The difference between the two pairs of ketones must evidently be attributed to the effect of the α-methyl group present in (III) and (IV) which has already been found to favour the βγ-phase in some cases (Kon and Narayanan, J., 1927, 1536), although no such effect was observed in the acids studied by Goldberg and Linstead (this vol., p. 2349). The great effect on mobility is certainly unexpected, and further work will be necessary before any explanation is attempted; it is therefore proposed to study several suitable cases in the near future.

EXPERIMENTAL.

Action of Acid Condensing Agents on Methyl Ethyl Ketone.

1. *Sulphuric Acid.*—Ice-cold methyl ethyl ketone was treated with one-tenth of its volume of sulphuric acid, the mixture kept for 24 hours, and worked up as described by Ekeley and Howe (*loc. cit.*). The yield of homomesitones was poor, generally about 10%, b. p. mainly 60—62°/17—19 mm., together with a fraction, b. p. 65—70°. The first fraction, $d_4^{20\cdot8°}$ 0·85845, $n_D^{20\cdot8°}$ 1·44552, was readily converted into a crystalline semicarbazone; this was fractionally crystallised from methyl alcohol, the less soluble portion being obtained in long, transparent laminæ, m. p. about 175°; on repeated crystallisation from ethyl alcohol, the m. p. rose to 203—204°, the compound being identical with the *semicarbazone* of (IV) (see below) (Found: N, 23·3. $C_9H_{17}ON_3$ requires N, 22·9%). The more soluble constituent of the original mixture was obtained in plates, m. p. 134°, evidently consisting of a "eutectic" similar to those previously obtained (compare Kon and Linstead, *loc. cit.*).

The fraction, b. p. 65—70°/17 mm., gave a semicarbazone from which iridescent, anthracene-like plates, m. p. 186°, were obtained on fractional crystallisation from methyl alcohol; these were identical with the semicarbazone of (III) (see below).

A somewhat better yield of homomesitones could be obtained by increasing the amount of condensing agent used; thus from 500 c.c. of methyl ethyl ketone and 200 c.c. of acid in four portions, 82 g., b. p. 53—85°/14 mm., were obtained, from which similar products were isolated.

2. *Hydrochloric Acid.*—The condensation was carried out as described by Ekeley and Howe; in later experiments, the mixture was kept for only 8 days. A yield of some 40% of homomesitone fraction was obtained, boiling mainly above 65°/20 mm.; the principal fraction, b. p. 65—67°/19 mm., had $d_4^{20\cdot4°}$ 0·8689, $n_D^{20\cdot4°}$ 1·45133. The same semicarbazone was obtained from all the fractions; it was purified by grinding with light petroleum, and fractionally crystallised from methyl alcohol. The first crops

usually melted at about 172° and had the characteristic anthracene-like appearance of the αβ-compound, m. p. 186°; repeated fractional crystallisation from methyl alcohol or acetone raised the m. p. to about 180°, whilst a compound of identical appearance, m. p. 166—167°, was present in the more soluble fraction and was evidently a stereoisomeride. Both semicarbazones gave rise to similar ketones: (*a*), from the high-melting semicarbazone, b. p. 53°/13 mm., $d_4^{18\cdot8°}$ 0·86722, $n_D^{18\cdot8°}$ 1·45313, $[R_L]_D$ 39·32; (*b*), from the low-melting semicarbazone, b. p. 53°/13 mm., $d_4^{19\cdot6°}$ 0·86567, $n_D^{19\cdot6°}$ 1·45233, $[R_L]_D$ 39·32; the same semicarbazones were obtainable from these ketones, although the higher-melting compound was clearly not quite homogeneous. This fact and the difficulty in eliminating all traces of halogen from the product caused us to abandon the use of hydrochloric acid as a condensing agent.

3. *Descudé's Method.*—The first experiment according to Descudé's directions (*loc. cit.*) gave a somewhat poor yield of homomesitone which was an inseparable mixture of αβ- and βγ-ketones (III and IV). The following simplified process gave good results: 300 G. of methyl ethyl ketone and 300 g. of acetyl chloride were cooled below 0°, and 120 g. of powdered zinc chloride added, the mixture being kept in the ice-chest for 2 days. Water and a little ether were added, and the oil was washed with sodium carbonate and added to a hot solution of 100 g. potassium hydroxide in 100 c.c. of water and 300 c.c. of alcohol, the mixture being boiled under reflux for 5 minutes. Water was then added, the oil extracted by ether, thoroughly washed, dried, and fractionated with a good column. The fractions obtained were: (*a*) up to 50°/20 mm., 30 g.; (*b*) 50—55°/18 mm., 9 g.; (*c*) 55—58°/17 mm., 22 g.; (*d*) 58—63°/16 mm., 27 g.; (*e*) 63—73°/15 mm., 38 g. Fractions (*b*), (*c*), and (*d*) were converted into the *semicarbazone* which formed characteristic plates, m. p. 186° after one crystallisation, and was identical with the synthetic specimen (see below) (Found: C, 59·0; H, 9·4. $C_9H_{17}ON_3$ requires C, 59·0; H, 9·4%). The ketone regenerated from it with oxalic acid had b. p. 53°/10 mm., 160°/750 mm., $d_4^{19\cdot5°}$ 0·86957, $n_D^{19\cdot5°}$ 1·45293, $[R_L]_D$ 39·19; it had a strong, pleasant odour. The fraction (*a*) consisted of methyl ethyl ketone and some of the βγ-ketone which could be isolated in the form of its semicarbazone. The fraction (*e*) still contained chlorine and was therefore again treated with alkali, whereby a mixture of the two homomesitones was obtained, the αβ- predominating. A greater proportion of the βγ-ketone was obtained on more prolonged treatment with alkali; thus, after 3 hours' boiling with sodium ethoxide in excess, it became the main product.

Synthesis of Ketone (III).—Methyl ethyl ketone was condensed

with ethyl α-bromopropionate in the presence of zinc to *ethyl β-hydroxy-αβ-dimethyl-*n*-valerate*, b. p. 89—90°/13 mm., $d_4^{19\cdot5°}$ 0·96457, $n_D^{19\cdot5°}$ 1·4319 (75% yield). The acid obtained by alkaline hydrolysis was liquid. It was dehydrated by boiling with acetic anhydride and gave a poor yield of *αβ-dimethyl-Δ$^{\alpha}$-pentenoic acid*, b. p. 116°/18 mm., $d_4^{17\cdot5°}$ 0·97497, $n_D^{17\cdot5°}$ 1·45952, $[R_L]_D$ 36·06 (calc., 35·60). The *acid chloride* boiled at 66°/17 mm., and gave a p-*toluidide* forming long needles, m. p. 123° (Found: C, 77·3; H, 8·7. $C_{14}H_{19}ON$ requires C, 77·4; H, 8·8%). The acid chloride was treated with zinc methyl iodide (compare Dickins, Hugh, and Kon, *loc. cit.*), giving a moderate yield of ketone which was converted into the semicarbazone and the latter recrystallised from methyl alcohol. The first crop separated in characteristic anthracene-like crystals, m. p. 180—182°, identical with the semicarbazone prepared by the Descudé method. Subsequent crops melted much lower and were evidently impure. The ketone, *γδ-dimethyl-Δ$^{\gamma}$-hexen-β-one* (III), regenerated from the first crop of semicarbazone had b. p. 65°/20 mm., $d_4^{17\cdot4°}$ 0·86856, $n_D^{17\cdot4°}$ 1·45283, $[R_L]_D$ 39·23, and was in every way identical with that obtained by Descudé's method.

Synthesis of Ketone (IV).—Ethyl β-hydroxy-αβ-dimethyl-*n*-valerate was readily dehydrated with phosphorus oxychloride in benzene, giving a 95% yield of *ethyl αβ-dimethyl-Δ$^{\beta}$-pentenoate*, b. p. 69°/13 mm., $d_4^{21\cdot1°}$ 0·92379, $n_D^{21\cdot1°}$ 1·43628. The *acid*, obtained by allowing the ester (1 g.-mol.) to stand at room temperature with 70 g. of sodium hydroxide in 700 c.c. of aqueous alcohol for 3 days (compare Linstead and May, J., 1927, 2565), had b. p. 116°/20 mm., $d_4^{18\cdot2°}$ 0·97002, $n_D^{18\cdot2°}$ 1·4498, $[R_L]_D$ 35·50 (calc., 35·60). The *acid chloride* boiled at 52°/13 mm., and gave a p-*toluidide* which had little tendency to crystallise but formed needles, m. p. 56°, from dilute alcohol (Found: C, 77·5; H, 8·7. $C_{14}H_{19}ON$ requires C, 77·4; H, 8·8%). The acid chloride gave on treatment with zinc methyl iodide a 50—60% yield of ketone, but an 85% yield was more readily obtained by slowly adding magnesium methyl iodide to a well-cooled ethereal solution of the acid chloride. The ketone was isolated in the form of its sparingly soluble semicarbazone; this separated very rapidly, and after one crystallisation melted at about 175°, rising to 203—204° after repeated crystallisation. The regenerated ketone, *γδ-dimethyl-Δ$^{\delta}$-hexen-β-one* (IV), had a characteristic camphoraceous odour, b. p. 48°/12 mm., 154°/750 mm., $d_4^{19\cdot2°}$ 0·85385, $n_D^{19\cdot2°}$ 1·43768, $[R_L]_D$ 38·74 (calc., 38·72). It was found that another *semicarbazone* was generally present and sometimes constituted the sole product; this had a very similar appearance (long, flattened needles) but melted at 163°, and the ketone regenerated from it was indistinguishable from the above,

b. p. 45°/10 mm., $d_4^{16\cdot9°}$ 0·85601, $n_D^{16\cdot9°}$ 1·4401, but gave the low-melting semicarbazone on treatment with semicarbazide. This ketone was frequently obtained as the main product on treating the intermediate fractions of the "Descudé ketone" with hot sodium ethoxide.

Equilibrium between Ketones (III) and (IV).—For the analysis of mixtures of the two ketones, the method of Linstead and May (*loc. cit.*) was used. The values obtained in 10 minutes with *M*/300-solutions in chloroform were

Mixture (% αβ)	0	10	25	50	75	90	100
% Iodine addition	81·8	77·7	69·6	50·6	28·4	14·5	3·4

from which a reference curve was constructed.

1. *Point of equilibrium.* Equilibrium was only slowly established at room temperature. Samples of the two pure ketones were therefore treated with a slight excess of sodium in methyl alcohol (4% solution) and warmed on the steam-bath under reflux for 6 hours; the ketones were then isolated as described by Dickins, Hugh, and Kon (*loc. cit.*), analysed iodometrically, and again treated with the reagent.

Initial material:	αβ-Ketone.			βγ-Ketone.	
Time (hours)	6	12	18	6	12
% Iodine addition	58·9	73·5	73·8	74·5	74·3
% αβ-Ketone	40·0	18·25	17·25	16·5	16·75

The equilibrium point is therefore 17 ± 0·25%.

2. *Mobility.* The first experiments were carried out by adding a cold solution of sodium (4 g.) in 75 c.c. of methyl alcohol to 18·3 g. of the ketone, making the volume up to 100 c.c. with methyl alcohol, and keeping the mixture at room temperature, 20 c.c. of solution being withdrawn at intervals for analysis.

Initial material:	αβ-Ketone.						
Time (hours)	24	48	72	96·5	121	235	422
% Iodine addition	11·7	16·6	18·4	22·4	27·0	37·9	46·2
% αβ-Ketone	92·5	87·5	85·5	81·05	76·5	64·75	55·5

Initial material:	βγ-Ketone.		
Time (hours)	96	165	306
% Iodine addition	79·5	78·9	78·1
% αβ-Ketone	5·75	6·75	9·0

The values for 235 and 422 hours were obtained by combining the five fractions of ketone isolated, taking them as corresponding to 72 hours, and again treating them with sodium methoxide. Only a few experiments were performed with the βγ-ketone, because this was apt to give erratic results. Finally, in order to obtain an estimate of mobility comparable with that of the ketones (I) and

(II) (see below), the αβ-ketone was treated with *N*-sodium methoxide (1 equiv.) at 25° :

Time (hours)	24	48	72
% Iodine addition	14·6	17·2	20·9
% αβ-Ketone	89·5	86·5	82·5

The change thus proceeded somewhat more quickly at 25°, although the total concentration of the reactants was lower.

Action of Alkaline Condensing Agents on Methyl Ethyl Ketone.

1. *Calcium Carbide.*—The condensation was carried out essentially as described by Bodroux and Taboury (*loc. cit.*); the yield of homomesitone fraction varied, the best being about 55%. On redistillation, the bulk of the product boiled at 67—70°/20 mm. and had $d_4^{22\cdot8°}$ 0·85523, $n_D^{22\cdot8°}$ 1·44973, $[R_L]_D$ 39·57; these properties indicate a high percentage of αβ-ketone, but this varies in different preparations. The semicarbazone was prepared in the usual way and proved to be an extremely intractable material from which only a minute proportion of pure substances could be isolated. Washing with light petroleum and fractional crystallisation from methyl alcohol led to the isolation of a very small amount of a less soluble constituent (in addition to the completely insoluble disemicarbazone already obtained by Ekeley and Howe, *loc. cit.*). This separated in pearly plates, m. p. 162°, and was the *semicarbazone* of the ketone (I) (see below) (Found : N, 23·1. $C_8H_{17}ON_3$ requires N, 22·9%). From the more soluble portions, less definite solids of varying m. p. were obtained, mainly the "eutectic" melting at 123°; this gave a ketone very similar in properties to the pure αβ-ketone, *viz.*, b. p. 50—52°/9 mm., $d_4^{18\cdot8°}$ 0·85731, $n_D^{18\cdot8°}$ 1·45193, $[R_L]_D$ 39·64. On one occasion a very small amount of needles, m. p. 156°, was isolated, which depressed the m. p.'s of all the other pure semicarbazones, but the amount was insufficient for investigation. On another occasion a preparation, m. p. 137°, was isolated which appeared to be a definite compound, and the ketone regenerated from it had b. p. 52—53°/12 mm., $d_4^{18\cdot8°}$ 0·85777, $n_D^{19\cdot8°}$ 1·45163, $[R_L]_D$ 39·63. On recombination with semicarbazide, a mixture was obtained from which a small amount of the compound of m. p. 162° could be isolated.

2. *Sodium Ethoxide.*—The following simplified preparation gave satisfactory results : Sodium (60 g.) was dissolved in ethyl alcohol (900 c.c.) and the excess of alcohol evaporated off under reduced pressure at about 80°; to the mixture, cooled in ice and salt, 500 c.c. of methyl ethyl ketone were added and the whole was kept for 24 hours with occasional shaking. Water was then added, the oil taken up in ether, well washed, dried, and distilled, the yield

of homomesitone fraction (b. p. 62—70°/19 mm.) being 90—100 g. The main bulk had $d_4^{21\cdot4°}$ 0·85656, $n_D^{21\cdot4°}$ 1·44502, iodine addition 34·3%. A specimen of the ketone prepared by the carbide process gave, on treatment with excess of sodium ethoxide, a product of very similar properties and iodine addition, which are characteristic of the equilibrium mixture of αβ- and βγ-ketone.

The semicarbazone of this equilibrium mixture was prepared, but it was again found impossible to isolate more than a small amount of pure material from it, although the αβ-semicarbazone, m.p. 162°, was obtained without great difficulty.

Synthesis of the Ketone (*I*).—β-Methyl-β-ethylacrylic acid was prepared as described by Kon and Linstead (J., 1925, **127**, 616) or by Fichter, Kieffer, and Bernoulli's method (*Ber.*, 1909, **42**, 4710). The acid chloride was then added to zinc ethyl iodide, and the moderate yield of ketonic fraction obtained was converted into the semicarbazone, which crystallised from methyl alcohol in anthracene-like plates, m. p. 162°, identical with the compound isolated from homomesitone (Found: C, 59·2; H, 9·3. Calc. for $C_9H_{17}ON_3$: C, 59·0; H, 9·3%). The regenerated ketone, *ε-methyl-Δ^δ-hepten-γ-one*, had b. p. 66°/18 mm., 53—54°/8 mm., $d_4^{21\cdot5°}$ 0·85516, $n_D^{21\cdot5°}$ 1·45073, $[R_L]_D$ 39·69 (calc., 38·72); its odour was strong and not very pleasant.

Isolation of Ketone (*II*).—Numerous attempts to obtain this ketone from β-methyl-Δ^β-pentenoic acid (Kon and Linstead, *loc. cit.*) by the action of zinc ethyl iodide on the chloride or of magnesium ethyl iodide on the amide were fruitless, although in the latter case a small amount of liquid with a ketonic smell was obtained but could not be purified. The chloride of the acid* was allowed to react with ethyl sodiomethylacetoacetate in ethereal solution, a good yield of the new ester, $CHMe{:}CMe{\cdot}CH_2{\cdot}CO{\cdot}CMe(CO_2Et){\cdot}COMe$, b. p. 158—168°/19 mm., being obtained; this was hydrolysed by boiling with 10% alcoholic sodium hydroxide for ½ hour, and the ketone formed isolated by distillation in steam: b. p. 74—76°/27 mm., $d_4^{20\cdot4°}$ 0·85595, $n_D^{20\cdot4°}$ 1·4453, $[R_L]_D$ 39·24. The semicarbazone was crystallised from methyl alcohol, and the resulting plates, m. p. 162°, were identified as the αβ-compound, showing that equilibration of the ketone had taken place during hydrolysis.

The ketone was finally isolated by treating the equilibrium mixture from the sodium ethoxide condensation with aluminium

* It should be noted that the acid prepared by the action of sulphuric acid on the hydroxy-acid (*loc. cit.*) contains some αβ-acid. The purest acid is obtained by the cold hydrolysis of the ester obtained by dehydrating the hydroxy-ester with phosphorus oxychloride or potassium hydrogen sulphate. The use of phosphorus pentoxide leads to a mixture of esters.

amalgam (Harries and Eschenbach, *Ber.*, 1896, **29**, 380), whereby the αβ-ketone was reduced to a high-boiling bimolecular condensation product; the unchanged βγ-ketone was then isolated by careful fractionation. The reduction was carried out twice to ensure the complete removal of the αβ-ketone, although the iodine addition of the product did not change. The new compound, *ε-methyl-Δ$^{\epsilon}$-hepten-γ-one*, thus obtained had b. p. 63°/19 mm., $d_4^{21\cdot2°}$ 0·85244, $n_D^{21\cdot2°}$ 1·43668, $[R_L]_D$ 38·73 (calc., 38·72); the odour of the ketone was more pleasant than that of the αβ-ketone and quite distinctive. Several different preparations had very similar properties and no saturated ketone, $C_8H_{16}O$, appeared to be produced in the reduction. The *semicarbazone*, although readily formed, was soluble and difficult to purify; it separated from methyl alcohol or ethyl acetate in indefinitely crystalline nodules, m. p. 134° (Found: N, 23·2. $C_9H_{17}ON_3$ requires N, 22·9%).

Equilibrium between the Ketones (I) and (II).—Mixtures of the two ketones were analysed iodometrically with the aid of a reference curve, constructed from the following figures:

Mixture (% αβ-)	0	10	25	50	75	90	100
% Iodine addition	75·3	71·6	64·2	48·7	29·4	16·2	7·8

the αβ-ketone used being regenerated from the pure semicarbazone; the βγ-ketone was the specimen described above.

1. *Point of equilibrium.* The βγ-ketone was treated with hot sodium methoxide for 6 hours and gave a product, $d_4^{20\cdot2°}$ 0·85898, $n_D^{20\cdot2}$ 1·4442, iodine addition 38·8%; on further treatment the value dropped to 35·4 and then remained constant. The ketone prepared by the method of Bodroux and Taboury and purified by regeneration from the semicarbazone was similarly treated and found to have the same iodine addition (35·3%). The composition of this mixture is 67·5% αβ-ketone. This incidentally proved that the βγ-ketone used was free from saturated impurities, otherwise a lower % addition of iodine would have been observed on complete equilibration.

2. *Mobility.* An exactly *N*-solution of sodium in methyl alcohol was added to each of the ketones in molecular proportion; the two mixtures were kept in a thermostat at 25°, and portions withdrawn at intervals for analysis gave the following result:

Initial material:	αβ-Ketone.						
Time (hours)	1	2	3	5	7	28	72
% Iodine addition	21·80	24·49	26·35	29·10	27·47	32·20	35·05
% αβ-Ketone	84·0	80·75	78·75	77·75	77·25	72·00	67·75

Initial material:	βγ-Ketone.					
Time (hours)	1	2	4	6	8	28
% Iodine addition	59·95	53·05	45·10	41·30	39·10	35·80
% αβ-Ketone	32·50	44·00	55·00	60·25	63·00	67·00

Ketone, $C_8H_{14}O$, *from Ethyl Ethoxycrotonate and Magnesium Ethyl Iodide.*—Blaise and Maire's preparation (*loc. cit.*) was repeated. The ketonic fraction (obtained in extremely poor yield) was treated with semicarbazide, and the resulting semicarbazone crystallised in small plates which did not felt together; it melted at 158° after several crystallisations from methyl alcohol and was not identical with any of the semicarbazones isolated in the course of this work. The ketone regenerated from it differed from the ketone (I) in smell, although its properties were otherwise very similar: b. p. 49°/8 mm., $d_4^{15\cdot5°}$ 0·86004, $n_D^{15\cdot5°}$ 1·45233, $[R_L]_D$ 39·58; it gave the same semicarbazone on recombining with semicarbazide. The high molecular refraction and low iodine value indicate an αβ-structure, but the quantity at our disposal did not allow of more thorough investigation.

The authors' thanks are due to the Royal Society and to the Chemical Society for grants which have defrayed the cost of this investigation.

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY,
SOUTH KENSINGTON, S.W. 7. [*Received, July 24th*, 1928.]

CCCXXXIV.—*The Chemistry of Aromadendrene. Part I.*

By LINDSAY HEATHCOTE BRIGGS and WALLACE FRANK SHORT.

DURING the course of his investigations, the late H. G. Smith recorded the presence of a sesquiterpene fraction in the oils obtained from about 140 species of the genus *Eucalyptus* (Baker and Smith, "A Research on the Eucalypts," Sydney, 1920, pp. 336—348), and he expressed the opinion (*op. cit.*, p. 417; *Proc. Roy. Soc. New South Wales*, 1901, **35**, 124) that aromadendrene is the only sesquiterpene present in eucalyptus oils. The largest amounts of aromadendrene were obtained from the oils of *E. nova-angelica* and *E. hæmastoma*, but a considerable quantity was also found to be present in those of *E. Dawsoni*, *E. eximia*, *E. trachyophloia*, *E. affinis*, *E. Maclurata*, *E. cebra*, *E. viminalis*, and *E. acmenoides*. It is probable that this sesquiterpene occurs in the oils of other genera, and it has been suggested tentatively that it is present in those obtained from *Angophora lanceolata* (Smith, *op. cit.*, pp. 17, 418), *Pinus Lambertiana*, Dougl. (Schorger, *U.S. Dept. of Agric. Forest Serv. Bull.*, 1913, No. 119), *Hypericum perforatum*, L. (Zellner, *Arch. Pharm.*, 1925, **263**, 161), *Leptospermum flavescens var. grandiflorum*, Bentham (Penfold, *Proc. Roy. Soc. New South Wales*, 1920, **54**, 198), *L. odoratum*, Cheel

(*idem, ibid.*, p. 205), *L. flavescens*, Smith (*idem, ibid.*, 1921, **55**, 171), *L. ericoides* (Johnson and Short, *Rep. Austr. Assoc. Sci.*, 1923, **16**, 220), *L. scoparium* (Short, *J. Soc. Chem. Ind.*, 1926, **45**, 96T), and *L. lanigerum*, Smith (Penfold, *Proc. Roy. Soc. New South Wales*, 1926, **60**, 79).

No solid derivatives of aromadendrene have hitherto been obtained, and for its identification it has been necessary to rely upon the physical constants and upon certain colour reactions, such as that produced by bromine in acetic acid solution. The same colour reactions are, however, exhibited by several dicyclic sesquiterpenes (*e.g.*, gaujene and eudesmene), so they are of very little diagnostic value.*

The purest specimen of aromadendrene isolated by Smith (*op. cit.*, pp. 46, 416) was obtained from the oil of *E. nova-angelica* and had the following physical constants: b. p. 124—125°/10 mm., $[\alpha]_D$ +4·7°, $n_D^{20°}$ 1·4964, $d_{15°}^{15°}$ 0·9222, $[R_L]_D$ 64·89 (calc. for a dicyclic sesquiterpene, 66·14; for a tricyclic sesquiterpene, 64·40). Semmler (" Ätherischen Öle," 1906, II, 530) suggested that aromadendrene is not an individual substance but possibly consists of a mixture of di- and tri-cyclic sesquiterpenes. In view of Semmler's criticism, and owing to the fact that no derivatives of aromadendrene had been obtained, it was impossible to establish definitely its identity with the sesquiterpene obtained by one of us (*loc. cit.*) from *Leptospermum* oils until further knowledge of the chemistry of aromadendrene had been acquired; such an investigation has now been made possible by the kindness of Mr. A. R. Penfold, Curator of the Technological Museum, Sydney, who supplied us with 1 lb. of an authentic sample of the oil of *E. nova-angelica*.

The sesquiterpene fraction of this oil was repeatedly fractionated in a vacuum over sodium–potassium alloy, a Widmer column being employed. The fractionation was controlled by determination of the refractive indices and optical rotations of the fractions, rather than by observation of the boiling ranges. After about twenty distillations, the sesquiterpene fraction was collected in two main fractions (representing about 20% of the original oil) and their physical constants (see p. 2527) pointed to the conclusion that the bulk of the sesquiterpene fraction consisted of a single tricyclic sesquiterpene exhibiting an exaltation of approximately one unit in its molecular refractive power. This conclusion has been verified by the preparation of a *dihydroaromadendrene* by exhaustive hydrogenation of the sesquiterpene by the methods of Skita and Paal. Both methods yielded the same result, so that isomerisation during

* Since the sesquiterpene alcohol eudesmol occurs in many eucalyptus oils, it may be anticipated that some of them will also contain eudesmene.

the hydrogenation is improbable. Since the dihydroaromadendren also showed an exaltation of one unit in molecular refractive power it is evident that the exaltation exhibited by the sesquiterpene is due to some structural peculiarity and not to its contamination with dicyclic sesquiterpenes. In this respect aromadendrene resembles the tricyclic sesquiterpenes α-gurjunene (Semmler and Spornitz *Ber.*, 1914, **47**, 1151) and copaene (Semmler and Stenzel, *ibid.*, p. 2555). It is probable, therefore, that aromadendrene contains either a *cyclo*propane ring conjugated with a double bond (as in sabinene) together with a *cyclo*butane ring, or, less probably, two *cyclo*propane rings.

Attempts to obtain solid addition products (nitrosite, nitrosate, nitrosochloride) from aromadendrene have not been successful. The hydrochloride, having approximately the composition $C_{15}H_{25}Cl$, is a liquid which cannot be distilled in a vacuum without considerable decomposition.

Dehydrogenation of aromadendrene with sulphur yielded a deep blue oil (b. p. 122—165°/12 mm.) from which no naphthalene hydrocarbon could be obtained, although a small quantity of a black picrate (azulene picrate?) was isolated from it. Aromadendrene therefore resembles the other tricyclic sesquiterpenes, with the exception of copaene (Henderson, M'Nab, and Robertson, J., 1926, 3077), in its inability to yield a naphthalene hydrocarbon on dehydrogenation with sulphur (Ruzicka, Stoll, Liebl, and Pontalti, *Helv. Chim. Acta*, 1923, **6**, 846).

Ozonisation of aromadendrene in acetic acid solution produced a compound, $C_{14}H_{22}O$ (m. p. 80—81°), approximately the same yield (60%) being obtained from each of the fractions above. This substance formed an *oxime* and a *semicarbazone*, and was at first considered to be an aldehyde, since, even when recrystallised to constant m. p., it reduced Tollens's reagent. The reduction, however, must have been due to contamination with traces of an impurity (probably formaldehyde), since the compound was devoid of reducing properties after it had been regenerated from its oxime. Moreover, the oxime did not yield a nitrile when it was digested with acetic anhydride. It therefore appears that the compound $C_{14}H_{22}O$ is a ketone, and we propose to call it *aromadendrone*.

Aromadendrone did not yield an enol-acetate when boiled with acetic anhydride and sodium acetate. This indicates that the carbonyl group is either situated in the side-chain or attached to two quaternary carbon atoms in the nucleus.

The results so far obtained indicate that aromadendrene is a tricyclic sesquiterpene, which probably contains a *cyclo*hexane nucleus with two bridges and is therefore allied in structure to

α-santalene (Semmler, *Ber.*, 1910, **43**, 446, 1898) and to longifolene (Simonsen, J., 1923, **123**, 2642). The results of ozonisation clearly show the presence of the group C·C(:CH_2)·C.

Experimental.

The fractions referred to on p. 2525 had the following properties: (1) b. p. 121°/10 mm., $[\alpha]_{577}^{20°}$ − 6·1°, $d_4^{20°}$ 0·9116, $n_D^{20°}$ 1·4978, $[R_L]_D$ 65·58; (2) b. p. 121—121·4°/10 mm., $[\alpha]_{577}^{20°}$ ± 0°, $d_4^{17°}$ 0·9157, $n_D^{17°}$ 1·4993, $[R_L]_D$ 65·44 [Found, for (1): C, 88·3; H, 11·8; for (2): C, 88·2; H, 11·9. $C_{15}H_{24}$ requires C, 88·2; H, 11·8%. $[R_L]_D$ for a dicyclic sesquiterpene, 66·14; for a tricyclic sesquiterpene, 64·40].

In addition to these two fractions a small first-running ($n_D^{20°}$ 1·4974, $[\alpha]_{577}^{20°}$ − 13·6°) and a small fraction (b. p. 124°/10·3 mm., $n_D^{20°}$ 1·4989, $[\alpha]_{577}^{20°}$ + 0·59°) were also obtained.

Hydrogenation.—(1) 12 G. of aromadendrene (fraction 2, freshly distilled over sodium), dissolved in pure methyl alcohol (200 c.c.), were hydrogenated in presence of 0·05% of colloidal palladium (Paal and Gerum, *Ber.*, 1908, **41**, 809) in the apparatus described by Skita and Meyer (*Ber.*, 1912, **45**, 3594), hydrogen from a cylinder being passed at slightly above atmospheric pressure for 20 hours. The product was poured into water, extracted with ether, dried, and distilled over sodium. The hydrogenation was then repeated with a further quantity of colloidal palladium (0·05%) and was found to be complete. The product, extracted in the usual way, was distilled over sodium, and practically the whole passed over at 121—122°/10 mm. (Found: C, 87·2; H, 12·7. $C_{15}H_{26}$ requires C, 87·4; H, 12·6%). *Dihydroaromadendrene* is a colourless oil having $d_4^{17°}$ 0·9014, $n_D^{17°}$ 1·4871, $[R_L]_D$ 65·83 (calc. for a tricyclic dihydrosesquiterpene, 64·87).

(2) Aromadendrene (fraction 2) was also exhaustively hydrogenated by Skita's inoculation method (*loc. cit.*). Addition of the inoculating solution to the aromadendrene–platinic chloride mixture and subsequent passage of hydrogen tended to yield a granular rather than a colloidal precipitate, and the hydrocarbon was therefore added after the colloidal condition had been induced. The aromadendrene (10·7 g.) was reduced in presence of colloidal platinum (0·95 g.), water (84 g.), and purified acetic acid (200 c.c.) at an excess pressure of 0·25 atm. Absorption of hydrogen ceased after about 6 hours and no further absorption occurred on the addition of more colloidal platinum. The purified product (Found: C, 87·4; H, 12·6%) had b. p. 115—116°/8—9 mm., $n_D^{22°}$ 1·4847, $d_4^{22°}$ 0·8972, $[R_L]_D$ 65·71.

Dehydrogenation.—Aromadendrene (8 g.; fraction 1) and sulphur

(4 g.) were heated together for 4 hours, during which the temperature was slowly raised from 210° to 290° and the evolution of hydrogen sulphide was completed. The reaction mixture was then distilled and purified by redistillation from potassium in a vacuum. The distillate (b. p. 122—165°/12 mm.) was a deep indigo-blue oil, from which no naphthalene hydrocarbon could be isolated (as picrate), but which yielded a trace of a black substance (m. p. 114—116°), possibly identical with eucazulene picrate (Ruzicka and Rudolph, *Helv. Chim. Acta*, 1926, 9, 118).

Aromadendrone.—A solution of aromadendrene (13 g.) in glacial acetic acid (60 c.c.) was cooled in ice-water and treated with a stream of ozonised oxygen (approx. 14% O_3) until a test portion no longer decolorised a dilute solution of bromine in acetic acid (2·5 hours). The straw-coloured liquid was concentrated under diminished pressure at 50—60° to half its volume, cautiously heated until incipient decomposition was observed, and the flask was then cooled in water to moderate the strongly exothermic reaction which took place. In the first experiments the ketone was recovered by steam-distillation, but it was subsequently found better to pour the cold residue into about six times its volume of ice-water, for the crystalline ketone then separated at once and could be filtered off. The filtrate, on neutralisation, deposited a small quantity (0·55 g.) of an amorphous, white solid which was not further examined. Crystallisation of the crude ketone (11·7 g.) from dilute acetone yielded 5 g. of pure substance, and another 3 g. were obtained by recrystallisation of the fraction of the mother-liquor boiling between 142·5° and 150°/10 mm. (total yield, 61%).

Aromadendrone crystallises in feathery, white needles (m. p. 80—81°) having a characteristic odour, and is very soluble in methyl and ethyl alcohols, chloroform, and acetone. It may be recrystallised from 60% alcohol or from acetone by dilution with water (Found: C, 81·4; H, 10·7; *M*, cryoscopic in benzene, 208·3, 207·6. $C_{14}H_{22}O$ requires C, 81·6; H, 10·7%; *M*, 206).

The *oxime* was obtained in almost theoretical yield by the interaction of aromadendrone with twice the theoretical quantities of hydroxylamine hydrochloride and sodium bicarbonate in 95% alcohol (44 hours at 56°). It crystallises in needles (m. p. 103°) from methyl alcohol (Found: N, 6·5, 6·4. $C_{14}H_{23}ON$ requires N, 6·3%).

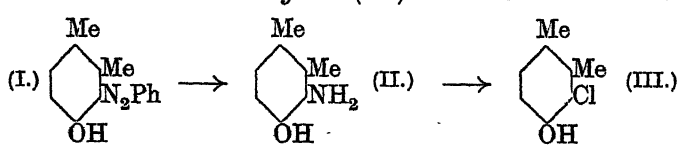
The *semicarbazone*, m. p. 189·5—190·5° (decomp.), prepared in the usual way, is a microcrystalline powder (from hot methyl alcohol) which is difficult to purify (Found: N, 15·7. $C_{15}H_{25}ON_3$ requires N, 16·0%).

Dehydration of the Oxime.—The oxime was boiled (1·25 hours) with twice its weight of purified acetic anhydride. The dark-coloured

product was worked up in the usual way, but yielded fractions of high boiling-point instead of a nitrile.

Aromadendrone and Acetic Anhydride.—The ketone (5 g.), purified acetic anhydride (10 g.), and fused sodium acetate (0·5 g.) were boiled together for ¾ hour. The product was cooled, shaken with water, and the crystals which separated were taken up in ether, washed with dilute sodium carbonate, dried, and distilled. Almost the whole passed over at 141—144°/10 mm., and the pure ketone (4 g.) was recovered from this fraction.

One of us (W. F. S.) wishes gratefully to acknowledge the receipt of a grant from the New Zealand Institute which enabled him to purchase the ozoniser and hydrogenation and micro-analytical apparatus. Our thanks are due to the Chemical Society for the loan of a vacuum pump, and to the authorities administering the Duffus Lubecki Fund for a scholarship which enabled one of us (L. H. B.) to participate in this investigation.



UNIVERSITY COLLEGE,

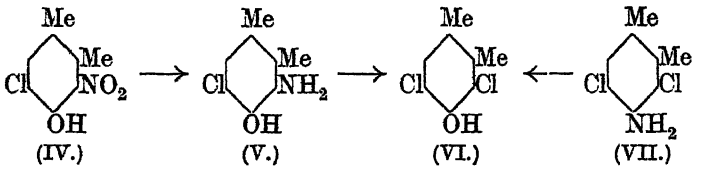
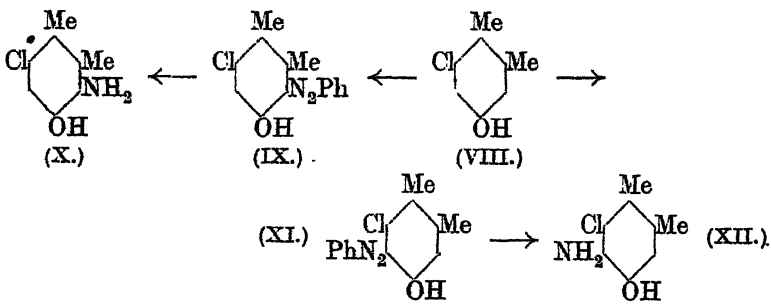
CCCXXXV.—*Chloro-o-xylenols. Part II. 3-Chloro-o-4-xylenol, the Dichloro-o-4-xylenols and 4 : 5-Dichloro-o-3-xylenol.*

By LEONARD ERIC HINKEL, ERNEST EDWARD AYLING, and LILIAN COLLIER BEVAN.



IN previous communications (J., 1923, **123**, 2968; 1924, **125**, 1847) six chloro-*o*-xylenols have been described; the syntheses of five of the eight remaining chloro-*o*-xylenols have now been completed.

The synthesis of 3-chloro-*o*-4-xylenol was achieved through *o*-4-xylenol, which was coupled with benzenediazonium chloride (Diepolder, *Ber.*, 1909, **42**, 2918; 1911, **44**, 2498), the 3-benzeneazo-*o*-4-xylenol (I) being separated from the accompanying 5-benzeneazo-*o*-4-xylenol, and reduced to 3-*amino*-o-4-*xylenol* (II), which was converted into 3-*chloro*-o-4-*xylenol* (III) in the normal manner.



3 : 5-*Dichloro*-o-4-*xylenol* was synthesised through 5-chloro-*o*-4-xylenol (Hinkel, Collins, and Ayling, J., 1923, **123**, 2973). The latter did not couple with benzenediazonium chloride, and was

therefore nitrated, and the resulting 5-*chloro*-3-*nitro*-o-4-*xylenol* (IV) reduced to 5-*chloro*-3-*amino*-o-4-*xylenol* (V). Replacement of the amino-group by chlorine did not yield a homogeneous product, although the similar action with 3-amino-*o*-4-xylenol (II) proceeded normally. The mixture of chloro-xylenols obtained from (V) probably resulted from either a partial elimination of the amino-group or its partial replacement by a second hydroxyl group instead of by chlorine. From the mixture a pure dichloro-*o*-4-xylenol was isolated, which was identical with 3 : 5-dichloro-*o*-4-xylenol (VI) subsequently prepared from 3 : 5-dichloro-*o*-4-xylidine (VII) (this vol., p. 1878), thus confirming the position of the nitro-group in (IV).

In an attempted synthesis of 5 : 6-dichloro-*o*-4-xylenol, 6-chloro-*o*-4-xylenol (VIII) (Hinkel, J., 1924, **125**, 1852) was coupled with benzenediazonium chloride, and the resulting azo-compound reduced to the corresponding amine, but attempted replacement of the amino-group by chlorine resulted in its unexpected elimination with regeneration of the starting material. Since, in the latter, both ortho-positions to the hydroxyl group are free, the coupling of the diazonium chloride can yield either of the azo-compounds (IX) and (XI), the product on reduction being either of the amines (X) and (XII).

In (X) the amino-group is situated similarly to those in (II) and (V), in which the amino-group can be replaced by chlorine. This serves in a measure to establish the constitutions of the azo-compound and the amine as 5-*benzeneazo*- (XI) and 5-*amino*-6-*chloro*-o-4-*xylenol* (XII) respectively, and the fact that 5-chloro-*o*-4-xylenol does not couple with benzenediazonium chloride (compare p. 2529),

whilst *o*-4-xylenol couples mainly in position 5 (compare Diepolder, *loc. cit.*), supports this view.

5 : 6-Dichloro-*o*-4-xylenol was finally prepared from 5 : 6-dichloro-*o*-4-xylidine (this vol., p. 1877) and is identical with the compound described by Hinkel (J., 1924, **125**, 1851).

4 : 5-*Dichloro*-o-3-*xylenol* and 3 : 6-*dichloro*-o-4-*xylenol* were prepared similarly from the respective dichloro-xylidines (this vol., p. 1876), although in no case does the replacement of the amino-group proceed smoothly.

EXPERIMENTAL.

3-*Amino*-o-4-*xylenol*.—3-Benzeneazo-*o*-4-xylenol, prepared according to Diepolder (*loc. cit.*), was finally purified by several crystallisations from light petroleum (b. p. 60—80°) and obtained as dark red crystals, m. p. 70°. The azo-compound was reduced in alcoholic solution with sodium hydrosulphite, and on removal of the alcohol under reduced pressure, a white solid separated which crystallised from benzene in small crystals, m. p. 126° (Found: N, 10·2. $C_8H_{11}ON$ requires N, 10·2%).

3-*Chloro*-o-4-*xylenol*.—3-Amino-*o*-4-xylenol was diazotised and treated with cuprous chloride in the usual way. Distillation with steam yielded an oil, which was extracted with ether, and the extract washed with sodium hydroxide solution. The xylenol, recovered from the alkaline solution by acidification and extraction with ether, crystallised from light petroleum (b. p. 40—60°) in transparent crystals, m. p. 27° (Found: Cl, 22·4. C_8H_9OCl requires Cl, 22·7%). The *benzoyl* derivative, prepared in the usual manner, crystallised from dilute alcohol in prisms, m. p. 87° (Found: Cl, 13·4. $C_{15}H_{13}O_2Cl$ requires Cl, 13·6%).

5-*Chloro*-3-*nitro*-o-4-*xylenol*.—To 1 g. of 5-chloro-*o*-4-xylenol (Hinkel, Collins, and Ayling, *loc. cit.*) in 10 c.c. of glacial acetic acid, 0·5 c.c. of nitric acid in 10 c.c. of glacial acetic acid was slowly added. After standing for 20 minutes, the mixture was poured on ice, and the precipitated solid distilled in steam. The solid distillate crystallised from benzene in yellow plates, m. p. 127·5° (Found: Cl, 17·6. $C_8H_8O_3NCl$ requires Cl, 17·6%).

5-*Chloro*-3-*amino*-o-4-*xylenol*.—5-Chloro-3-nitro-*o*-4-xylenol was reduced in alcoholic solution with sodium hydrosulphite. On removal of the alcohol under reduced pressure, a white solid was precipitated which crystallised from alcohol in very fine needles, m. p. 175°, with considerable darkening just below the m. p. (Found: Cl, 20·3. $C_8H_{10}ONCl$ requires 20·7%).

3 : 5-*Dichloro*-o-4-*xylenol*.—(1) 5-Chloro-3-amino-*o*-4-xylenol (2 g. in 240 c.c. of hydrochloric acid) was diazotised at 0°, poured into

cuprous chloride solution, distilled with steam, and the distillate extracted with ether. The extract was washed with sodium hydroxide solution, and the alkaline solution yielded a mixture of xylenols which, on fractional crystallisation from light petroleum (b. p. 60—80°), yielded mainly 3 : 5-*dichloro*-o-4-*xylenol* as feathery crystals, m. p. 52°, the constitution being confirmed by the synthesis described below (Found: Cl, 36·8. $C_8H_8OCl_2$ requires Cl, 37·2%). The *benzoyl* derivative crystallised from light petroleum (b. p. 40—60°) as white crystals, m. p. 89° (Found: Cl, 23·6. $C_{15}H_{12}O_2Cl_2$ requires Cl, 24·1%).

(2) 3 : 5-Dichloro-*o*-4-xylidine (this vol., p. 1878), dissolved in concentrated sulphuric acid, was diazotised at 0°, poured into dilute sulphuric acid, and steam-distilled. The distillate, which consisted mainly of 3 : 5-dichloro-*o*-xylene (4 : 6-dinitro-derivative, m. p. 175°; compare Crossley and Renouf, J., 1904, **85**, 284) together with a small quantity of the xylenol, was extracted with ether, and the extract washed with sodium hydroxide solution. The xylenol, obtained from the alkaline solution in the usual manner and purified from light petroleum (b. p. 60—80°), was identical with the 3 : 5-dichloro-*o*-4-xylenol described above.

6-*Chloro*-5-*benzeneazo*-o-4-*xylenol*.—The requisite amount of benzenediazonium chloride solution was coupled with 2·6 g. of 6-chloro-*o*-4-xylenol (Hinkel, *loc. cit.*) in slightly alkaline solution. The precipitate crystallised from alcohol in red needles, m. p. 143° (Found: Cl, 13·6. $C_{14}H_{13}ON_2Cl$ requires Cl, 13·4%).

6-*Chloro*-5-*amino*-o-4-*xylenol*.—The foregoing azo-compound was reduced in aqueous-alcoholic solution with sodium hydrosulphite; removal of the alcohol under reduced pressure precipitated a white solid, which crystallised from dilute alcohol in fluffy needles, m. p. 144·5° (Found: Cl, 20·1. $C_8H_{10}ONCl$ requires Cl, 20·7%). Diazotisation of the amine and treatment with cuprous chloride in the usual manner, followed by distillation with steam, yielded a white solid, which was extracted with ether, and then crystallised from light petroleum (b. p. 60—80°) in fine needles, m. p. 98°, unchanged by admixture with 6-chloro-*o*-4-xylenol, m. p. 98°.

5 : 6-*Dichloro*-o-4-*xylenol*.—5 : 6-Dichloro-*o*-4-xylidine (this vol., p. 1877), 0·5 g. at a time, was dissolved in 5 c.c. of sulphuric acid; the sulphate was precipitated in a finely divided state by the addition of 10 c.c. of water, diazotised at 0°, and gently warmed to 40° until a clear solution was obtained. The diazotised solution was treated according to the method of Heinichen (*Annalen*, 1889, **253**, 281; compare Cain and Norman, J., 1906, **89**, 19) by the addition of 20 c.c. of concentrated sulphuric acid, but modified by heating the acid solution for 1 hour on a steam-bath. Other methods of treat-

ment (compare Cain and Norman) result in the formation of much red solid, which is reduced to a minimum by the above procedure. The acid solution was distilled with steam, the solid distillate treated with dilute sodium hydroxide solution, the solution filtered, and the xylenol recovered in the usual manner; it crystallised from well-cooled light petroleum (b. p. 60—80°) in tiny rosettes, m. p. 102·5° (Found: Cl, 36·6. Calc. for $C_8H_8OCl_2$: Cl, 37·2%). The benzoyl derivative crystallised from dilute alcohol in stellate groups, m. p. 97·5° (Found: Cl, 23·8. Calc. for $C_{15}H_{12}O_2Cl_2$: Cl, 24·1%). These m. p.'s were unchanged by admixture with the corresponding compounds described by Hinkel (J., 1924, **125**, 1851).

3 : 6-*Dichloro*-o-4-*xylenol*.—3 : 6-Dichloro-*o*-4-xylidine (this vol., p. 1878) was dissolved by heating in 30% sulphuric acid. The finely divided sulphate obtained on cooling was diazotised at 40°, poured into boiling 40% sulphuric acid, and distilled with steam. The solid distillate was treated with dilute sodium hydroxide solution, the solution filtered, acidified, and extracted with light petroleum (b. p. 40—60°). The xylenol crystallised in long, flat needles, m. p. 84° (Found: Cl, 36·8. $C_8H_8OCl_2$ requires Cl, 37·2%). The *benzoyl* derivative crystallised from methyl alcohol in transparent, flat needles, m. p. 124° (Found: Cl, 23·8. $C_{15}H_{12}O_2Cl_2$ requires Cl, 24·1%).

4 : 5-*Dichloro*-o-3-*xylenol*.—4 : 5-Dichloro-*o*-3-xylidine (this vol., p. 1876) was treated exactly as in the preceding case, and the xylenol, recovered in the usual manner, crystallised from light petroleum (b. p. 60—80°) in stellate masses, m. p. 90° (Found: Cl, 36·5. $C_8H_8OCl_2$ requires Cl, 37·2%). The *benzoyl* derivative crystallised from dilute alcohol in prisms, m. p. 133° (Found: Cl, 24·3. $C_{15}H_{12}O_2Cl_2$ requires Cl, 24·1%).

UNIVERSITY COLLEGE, SWANSEA. [*Received, July 24th*, 1928.]

CCCXXXVI.—*The Conditions determining the Thermodynamic Stability of Cyanohydrins of Carbonyl Compounds. Part I. Some Effects of* (a) *Substitution in Aromatic Aldehydes and* (b) *Ring Formation.*

By ARTHUR LAPWORTH and RICHARD HELMUTH FRED MANSKE.

SINCE the condition of equilibrium attained by a system undergoing a reversible thermal chemical change is subservient to the laws of thermodynamics and independent of considerations such as

the relative velocities of the reactions by which the final state is attained, it follows that any factor connected with the constitution of one or more of the molecular species concerned, which is found to produce a definite alteration in the condition of equilibrium, is one which affects the " static " or average condition of the individual molecules. The adjective " static " is here used with full recognition of the principle that there is always a great variety of deviations from the average.

In recent discussions of the theory of mechanism of reaction of carbon compounds, there has been evident a tendency to regard some of the factors which control chemical change as operating primarily on reaction velocity and others on the conditions of equilibrium. Among the factors which have been most frequently considered are those to which Flürscheim originally applied the distinguishing terms " quantitative " and " electropolar " (compare J., 1909, **95**, 725). These two terms are retained throughout the present paper, being regarded as defined, not by any special hypothesis, but rather by the practical criteria originally laid down by Flürscheim.

The work of Victor Meyer and his pupils revealed the depressant effect of ortho-substituents on the rates of hydrolysis of benzoic esters. Flürscheim showed that all substituents when present in the ortho-position also have the effect of raising the ionisation constant of benzoic acids, no matter what the signs of the quantitative and electropolar factors. He attempted to account for this kind of effect by the introduction of a theory which had a kinetic basis (*loc. cit.*). His explanation still has a wide popularity, but is not accepted by the present authors, for it virtually postulates a mechanism by the automatic operation of which the second law of thermodynamics is rendered inoperative; the case is, in fact, one in which the principle restated in the foregoing paragraphs can be usefully applied. Since the ionisation constant of an acid at any given temperature and pressure and in any given solvent is simply a function of the increase in the free energy which is associated with the complete ionisation (including any simultaneous change of solvation) of 1 g.-mol. of the un-ionised acid as it exists in the solution, it is evident that the so-called " steric " factor does not, in this instance at least, operate primarily by modifying the speed at which a given change in entropy occurs, but actually alters the chemical potentials or entropies of the individual ions or molecules (or both) concerned.

Flürscheim also discovered and demonstrated in convincing manner that, not only the so-called " steric " factor, but also the quantitative and electropolar factors make themselves felt in the

magnitudes of ionisation constants. It follows of necessity that all three factors affect the entropies of the separate molecules or ions or both. The data now given (see Experimental) seem to show beyond doubt that neutral molecules are influenced by all three factors, and it would be unreasonable to assume that the same is not also true of ions.

It should now be clear that, if the alternate effects associated with the factor which Flürscheim termed "quantitative" be admitted to have a polar origin, then it would not be logical to maintain that polar considerations primarily affect reaction velocity (compare E. H. Ingold, J., 1925, **127**, 470).

Evidence obtained during the course of measurements of cyanohydrin equilibria (on which subject the experimental section of the present paper forms the first communication) indicates the operation of other factors which are not conspicuous in the study of ionisation of carboxylic acids or of aromatic substitution. Whilst the substituents NMe_2, OH, OCH_3, Cl, and CH_3 produce on the stability of benzaldehydecyanohydrin effects which are not inconsistent with prevailing views on the modes of operation of their quantitative and electropolar factors, the nitro-group appears out of place (p. 2546). There is already evidence that the nitro-group is not singular among meta-directive substituents in simulating the properties of ortho-para-directive substituents when the practical issue is the reduction in the additive power of a carbonyl group. Thus Mr. Glyn Owen, in these laboratories, has found that the cyanohydrin of benzoylformic ester has a somewhat higher dissociation constant than benzaldehyde, and as it is well known that the carbonyl group of ethyl benzoate has but very feeble additive properties, it is clear that in respect to efficiency in producing such results CO_2Et also comes between H and OEt.

The tendency of two or more double bonds (this term being applied to systems present in ethylenes, in $\cdot NO_2$, $\cdot CO\cdot Alk$, and $\cdot CO_2Alk$) to arrange themselves alternately with single bonds indicates that such an arrangement is ordinarily associated with an element of stability (*i.e.*, of large entropy) which must therefore operate unfavourably on any chemical change in which that arrangement is destroyed. There is no reason to believe that this factor is *necessarily* associated with polarisation. It will hereafter be referred to as the "Thiele factor," in view of the circumstance that the term "conjugation" is now commonly applied in a much wider sense. This factor would operate so as to stabilise, though to a quite unknown extent, the carbonyl form in a ketone or aldehyde of the types $CR^1R^2{:}CR^3{\cdot}CR^4{:}O$, $O{:}CR^1{\cdot}CR^2{:}O$, and probably also $NO_2{\cdot}CR{:}O$. This may conceivably account for some

apparent abnormalities in cyanohydrin formation, but there is yet another possibility which must not be overlooked.

The symbol $\overset{+}{A}_0 \rightharpoonup A_1$, etc., was first used by one of us in an attempt to account for the alternate effects (associated with the quantitative factor) to which such substituents as NMe_2, OEt, CH_3, etc., in position A_0 give rise when they are attached directly to carbon in position A_1 in certain atomic assemblages. The symbol implied (1) an increase in the covalence between A_0 and A_1, and (2) a movement of Faraday tubes equivalent to a drift or displacement of electrons, relatively to nuclei, in the direction indicated by the arrow.

The view may now be expressed that what is here essential is (1) the direction of electron displacement, and (2) the resulting change in the properties of A_1 and the atoms to the right of A_1. If it be assumed, for simplicity in the first instance, that the molecule terminates at A_1, the operation suggested in the figure would clearly imply that the nucleus of A_1 is engaged with an increased share of electrons, and consequently the restraint which it can exercise over its proper valency electrons must diminish, much as if some of its central charge has been removed. The "fugacity" of the valency electrons of A_1 has increased.

It is not apparent that there is any mode of ascertaining how far an observed change in the restraint on the valency electrons of an atom caused by replacement of H by A_0 (when A_0 is, for example, CH_3) can be ascribed to change in the value of the covalency, how far to simple electron displacement relative to nuclei (electron drift), or how far to an external electrostatic field, such as one arising out of the formation of the arrangement A_0—A_1, etc., from H—A_1, etc. It is rather the *sum total* of these which we may hope to detect, and possibly to estimate roughly, by observing either the change in the properties of A_1 or the consequent effects of this change on the rest of the molecule. The latter method was in principle the practical basis of the criteria used by Flürscheim.

Henceforward, therefore, the modified form $\overset{+}{A}\underset{\Sigma}{\rightharpoonup}A_1$, etc., will be used to denote an arrangement in which the replacement of H in H—A_1, etc., by A_0 produces, *by all effects from the left combined* (as indicated by Σ), an increase in the fugacity of the valency electrons of A_1, and this will be termed the "primary" interior effect of the substitution process. It is held that the classification of substituents based on Flürscheim's criterion for the quantitative factors gave the most satisfactory means hitherto discovered of ascertaining primary interior effects, *i.e.*, of ascertaining whether,

and roughly to what relative extent, a given substituent normally increases or decreases the fugacity of the valency electrons of a tervalent carbon atom at which substitution occurs. Those substituents, like NMe_2, OEt, Cl, and alkyl, which produce the same type of quantitative effect as a negative charge would do, are supposed to be those which by such substitution raise, on the whole, the fugacity of the electrons of A_1, when A_1 is a tervalent * or bivalent carbon atom. Substituents such as NO_2, CO·R, and NMe_3^+ in place of A_0 are imagined to be those which in their totalised effect on A_1 (where A_1 is tervalent or bivalent carbon) reduce the fugacity of its valency electrons.

It should be noted that the hypothesis above defined has definite reference to effects on tervalent and bivalent carbon only. Evidence as to how such groups as NMe_2, OH, or OAlk affect the restraint on valency electrons of an attached saturated (quadrivalent) carbon atom is not conclusive, but the change is certainly small. It is the *difference* between the effects on quadrivalent and tervalent or between tervalent and bivalent carbon to which attention must be paid in considering the stability of covalence attachments.

In connexion with the stability of the cyanohydrins of aldehydes and ketones, Robinson and Rây have explained how a substituent which increases the fugacity of the electrons of the carbon atom of a carbonyl group virtually endows that atom with an increased negativity, which must tend to decrease its attraction for negative ions such as CN^- (J., 1925, **127**, 1610). The present authors concur in this idea in so far as the electrostatic attraction is concerned, but suggest that something even more far-reaching may be postulated.

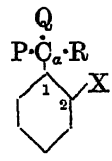
It has been suggested above that introduction of a substituent such as NMe_2, OH, OCH_3, Cl, or CH_3 in place of H produces a *totalised* effect on unsaturated carbon which is equivalent to a decrease in the restraint exercised by the central positive charge on the octet. With such an alteration, the atom will tend to display properties approaching those of boron. It follows that those structures in which the atom displays tervalency will become more stable *relatively to those in which it displays quadrivalency*. Consistently with this, the capacity of carbonyl to form stable, neutral, addition

* "Tervalent" is applied in the present paper to an atom which is exercising the co-ordination number 3, in the sense originally intended by Werner. Thus, carbon in ethylene, carbonyl, and carboxyl is described as "tervalent," and carbon in carbon dioxide as "bivalent." This application of such terms is in no way novel (compare Smith's "Inorganic Chemistry," by J. Kendall, G. Bell and Sons, Ltd., 1927, pp. 158—161), and has now been adopted in view of recent tendencies to restrict the use of the term "co-ordination."

products with H·CN, H·OH, and H·NH_2 decreases wherever the present theory, by utilising Flürscheim's criteria, predicts a large increase in the fugacity of the electrons of the carbonyl carbon atom, providing that the constitution of the substituent is not such as to form with the rest of the molecule a system with alternate single and double linkages and, therefore, is not such as to provide the carbonyl compound with an added non-polar element of stability ("Thiele factor," p. 2535). With singly bonded substituents, X in X·CO·R, it may with confidence be stated that the stability of the carbonyl addition products with neutral agents of the type above specified will be found to increase in the order: X = NMe_2, OAlk, Alk, (H). The truth of this is obvious enough in its application to the large contrast between OMe and CH_3 (in esters and ketones) and even to the comparatively small contrast between CH_3 and H, as consideration of the gradation in properties of CH_3·CO·CH_3, H·CO·CH_3, and H·CO·H will show.

If the analogy of changing central restraint suggested above may legitimately be pursued further, it may be inferred that replacement of H in H·C^1R:X by a substituent of the meta-directive type, such as NO_2 or CO·R, would have an effect on the carbon atom C^1 equivalent to an increase in the central charge on the latter. The atom C^1 might be said to show more "positiveness" in consequence of this; but it does not necessarily follow from this that the atom would more readily form a more stable covalency link by combination with a CN^- or OH^- ion. On passing from boron through carbon and nitrogen to oxygen, with increasing nuclear charge the capacity of the atom to exercise the co-ordination number 4 rises to a maximum and then decreases. Similarly, as A_0 in A_0·C^1R:X is replaced successively by NMe_2, OMe, CH_3, H, CO·R, and NO_2, the compound becomes more cationoid, but the relative stability of the addition product in which C^1 is quadrivalent may attain a maximum (not *necessarily* at hydrogen), and then decline. In this connexion it is very significant that on passing from, say,

$$(EtO)\text{—}\dot{C}^1\text{=}\dot{C}^2\text{·H} \quad \text{and} \quad (C\text{:}C)\text{—}\dot{C}^1\text{=}\dot{C}^2\text{·H} \quad \text{to} \quad (CO_2Et)\text{—}\dot{C}^1\text{=}\dot{C}^2\text{·H}$$



there is a development of electron-accepting (cationoid) properties in the system C^1=C^2; but nevertheless it is still C^2 and not C^1 which retains the greater tendency to combine with the "active" (or carbon-covalence-seeking) part of the agent [CN in HCN; $CH(CO_2Et)_2$ in ethyl sodiomalonate; Ar·N_2 in diazo-compounds; NO_2 in HO·NO_2].

It is desirable that it should be realised from the outset that the primary interior effect of a given substituent on an atom varies,

even in sign, with the nature of the atom at which substitution takes place. Thus, replacement of H in HCl^1 by Cl^2 does not increase the fugacity of the electrons of Cl^1; on the contrary, the product now shows nothing but strongly electron-seeking properties. Boron, on the other hand, resembles carbon, for while boron, in its hydrides, displays consistent quadrivalency, no neutral chloride is known in which boron displays a valency greater than three.

All ortho-substituents (other than OH) hitherto examined greatly increase the stability of the cyanohydrin group (see Table I), no matter what the quantitative or electropolar factors may be. This is quite irreconcilable with the idea that substituents so placed produce their effect in virtue of their occupation of space (compare also Kuhn and Wassermann, *Helv. Chim. Acta*, 1928, **11**, 3 *et seq.*).

In comparing the effects of ortho-substituents on the dissociation constants of cyanohydrins, on the one hand, and on the ionisation of carboxylic acids, on the other, it is natural to observe that both phenomena might at first sight be accounted for by assuming that a substituent X in position 2 in the annexed figure decreases the fugacity of electrons of C_α and, therefore (by consequent electron displacements), of the electrons of the atoms attached to C_α.

Having regard, however, to the possibility (for which reasons have been given above) that a large decrease in the fugacity of the electrons of C_α may not necessarily decrease the capacity of C_α to become quadrivalent, an alternative must not be overlooked. That alternative is a " direct " effect of X through space on the atoms or groups attached to C_α, rather than an effect on C_α itself, and it must in any case be an effect which both helps C_α to exercise its maximum co-ordination number and reduces the fugacity of the valency electrons of the atoms P, Q, and R attached to C_α; the latter requirement is shown by the decreased ability of the oxygen of ortho-substituted benzoic acids to retain a proton.

The most useful and significant measurements of thermodynamic changes associated with addition reactions of carbonyl compounds are certainly those of Adkins and Adams (*J. Amer. Chem. Soc.*, 1925, **47**, 1368), who studied the free energy of the formation of acetals from alcohols and carbonyl compounds, both aldehydes and ketones, by means of equilibrium measurements. This reaction, however, is highly complex, involving at equilibrium six molecules of four different chemical species :

$$2R'\cdot OH + R''\cdot CO\cdot R''' \longleftrightarrow R''\cdot C(OR')_2\cdot R''' + 2H_2O.$$

The ideal case for study is no doubt that in which only two

molecules of two chemical species are concerned at equilibrium (exclusive of catalysts), $A \longleftrightarrow A^1$, corresponding with the phenomenon of simple isodynamic change. Next to this in simplicity come two cases where three molecules are concerned:

$$(a) \quad A + A \longleftrightarrow C \text{ (two species)}$$
$$\text{or} \quad (b) \quad A + B \longleftrightarrow C \text{ (three species).}$$

Here, (*a*) would include all the simplest cases of polymerisation, and no simpler example of (*b*) could be taken than that of reversible cyanohydrin formation: $R_2CO + HCN \longleftrightarrow R_2C(OH)\cdot CN$, which is probably a simpler case than that of oxime or hydrazone formation (Petrenko-Kritschenko, *Ber.*, 1901, **34**, 1702; *Annalen*, 1905, **341**, 150; *Ber.*, 1906, **39**, 1454; Fischer, *Annalen*, 1886, **236**, 146; Stewart, J., 1905, **87**, 185, 410) and corresponds more closely with the formation of bisulphite double compounds (Stewart, *loc. cit.*).

Ultée (*Rec. trav. chim.*, 1909, **28**, 248, 257) examined the stability of a number of cyanohydrins, mainly by admixture of an aldehyde or ketone with anhydrous hydrogen cyanide in equimolecular proportion and in absence of solvent. The results were not in a form suitable for quantitative comparison, and this was more especially the case with aliphatic aldehydes, the cyanohydrins of which are so stable that the concentrations of the free hydrogen cyanide and of the free aldehyde (which could only be estimated by difference) were very uncertain. The equilibrium constants calculated for Ultée's liquid systems are not directly comparable with those given in the present paper, which refer to a different medium.

W. J. Jones (J., 1914, **105**, 1560) compared the dissociation constants of one or two cyanohydrins in aqueous solution, and confirmed Ultée's conclusion that in general the formation of cyanohydrins is incomplete, even with aldehydes; he made a quantitative comparison between the values of the equilibrium constant $K = C_{R_2CO} \times C_{HCN}/C_{R_2C(OH)\cdot CN}$ in aqueous solution and found the constant for acetone to be about eleven times as large as that for acetaldehyde.

The present authors have extended this work and made observations with a large number of aldehydes and ketones; but, as water is not generally suitable as a solvent, 96% alcohol was used as the medium throughout. Chemically, the principle on which the measurements were based was the same as that applied by Ultée and by Jones; it has recently been discussed at sufficient length by Lapworth, E. B. Robinson, and Manske (J., 1927, 2052 *et seq.*), and it is only necessary here to give details of the modified procedure adopted during the present research.

EXPERIMENTAL.

Preparation and Purification of the Aldehydes and Ketones.—Exigencies of space make it impracticable to give details for so many different compounds. Where the aldehydes or ketones were solids with a fairly high melting point, the procedure, as a rule, was fairly straightforward, and frequent recrystallisation from suitable solvents was always resorted to in the final stages—as, for example, where a nearly pure sample had been made synthetically or purchased as "pure" from a firm of repute and had passed the necessary preliminary tests satisfactorily. Where the compounds were liquids or low-melting solids, the methods of preparation adopted often afforded the necessary preliminary guarantee of homogeneity, and the elimination of most of the remaining impurities was always attempted by applying Richards's method of repeated distillation, with rejection of large initial and final fractions (compare *J. Amer. Chem. Soc.*, 1912, **34**, 978) even when the boiling-point range of the original material was very narrow. In each fractionation, wherever practicable, only the middle two-thirds of the distillate were utilised, so that when several successive operations were carried out, the proportion ultimately retained was very small. Oxidisable or hygroscopic compounds were fractionated in an atmosphere of dry carbon dioxide and then used immediately with every necessary precaution to avoid access of air or moisture.

In all cases where the aldehyde or ketone gave a crystalline bisulphite compound this was made as a stage in the preparative process.

In the following cases the starting materials used, and subjected to further treatment on the lines above indicated, were the best products made by British Drug Houses, Ltd.: Fluorenone and *o*-chloro-, *o*-nitro-, *m*-hydroxy-, *p*-hydroxy-, and *p*-dimethylaminobenzaldehydes.

The original *p*-nitrobenzaldehyde was purchased from Kahlbaum. In the case of *o*-nitrobenzaldehyde, traces of *o*-nitrosobenzoic acid present were easily removed by two successive precipitations from benzene solution by addition of light petroleum. The crude methoxybenzaldehydes were made by methylating the purified hydroxy-aldehydes; *m*-nitrobenzaldehyde was made by the method described in Erdmann's "Anleitung der Organischen Preparate" (Stuttgart, 1894), and *p*-methoxy-*m*- and -*o*-methylbenzaldehydes were made by the application of Gattermann's process to pure *o*- and *m*-cresol respectively.

Crude *m*-chloro- and *m*- and *p*-methyl-benzaldehydes were obtained from the corresponding chloro- and methyl-benzonitriles by Stephen's process (J., 1925, **127**, 1874). It is worthy of remark

that, owing to the retardation of reaction velocity ("steric hindrance"), this process did not prove satisfactory in the hands of the present authors for converting *o*-methylbenzonitrile into *o*-tolualdehyde, and it has not been possible to include any measurements on the cyanohydrin equilibrium in the case of the latter compound.

The original sample of *cyclo*pentanone was made from adipic acid by the method described in D.R.-P. 256,622; that of *cyclo*hexanone was purchased from Poulenc Frères. The methyl*cyclo*hexanones were made by catalytic reduction of pure cresols supplied by the Graesser Monsanto Co. The *cyclo*heptanone used was a specimen of this costly product kindly presented by Professor J. F. Thorpe; it was subsequently twice redistilled, small initial and final fractions being rejected as usual.

The following compounds were made in accordance with the authorities quoted: α-Ketotetrahydronaphthalene (Ingold and Piggot, J., 1923, **123**, 1483; compare also Kipping and Hill, J., 1899, **75**, 148), xanthrone (Perkin, *Ber.*, 1883, **16**, 339), and anthrone (Barnett and Cook, J., 1921, **119**, 904). In other cases the products were prepared by methods in general use.

Method of Determining the Equilibrium Constant.—The solvent used throughout was the binary constant-boiling 96% alcohol–water mixture, made from the strongest commercial spirit. This was purified by distillation first from 2% of its weight of oxalic acid, then from 5% of sodium hydroxide, and was finally carefully fractionated.

The anhydrous hydrogen cyanide was prepared from potassium ferrocyanide and dilute sulphuric acid, the vapours being conducted through a series of drying tubes containing calcium chloride, liquefied by cooling, and redistilled from phosphoric oxide.

Liquid aldehydes and ketones were weighed by difference from Lunge pipettes. This had numerous advantages, including ease in manipulation, increased accuracy by reduction of losses due to evaporation and oxidation, and prevention of access of moisture; moreover, by counting the drops, a rough control over the quantities used could be exercised.

A sufficient speed of reaction was ensured by the addition of a drop of *n*-tripropylamine, and it was ascertained that variations in the quantity of this base within limits many times wider than those which could accidentally be reached in practice had no measurable influence on the state of equilibrium. The equilibrium was finally "frozen," as in the experiments of Ultée and of Jones, by addition of excess of nitric acid.

In detail the operations were carried out as follows. A weighed amount of aldehyde or ketone was introduced into a 50 c.c. flask,

followed in succession by 30 c.c. of the alcoholic medium and 10 c.c. of the alcoholic hydrogen cyanide.* A very small drop (approximately 0·02 c.c.) of *n*-tripropylamine was added, and the mixture diluted to 50 c.c. with the solvent, confined with a glass stopper, and sealed with paraffin wax. Blank experiments, in which the operations were conducted in exactly the same way but without addition of the aldehyde or ketone, were carried out in each case to determine the total amount of hydrogen cyanide in the system. All solutions were thoroughly mixed, allowed to remain at room temperature over-night, and then kept at 20·0° ± 0·5°, at which temperature any slight contraction, frequently observed after reaction, was corrected, the volumes being made up to the original 50 c.c. by addition of more solvent. Equilibrium in most cases was attained in ½ hour, but this was always checked by comparison with titrations made on the following day.

Among all the cases which the authors have now investigated, that of *o*-nitrobenzaldehyde was the only one in which there was considerable irregularity in the amount of uncombined hydrogen cyanide present after standing for several days, and this was probably due to the extraordinary readiness with which this particular cyanohydrin undergoes complex changes (*Ber.*, 1904, **37**, 948).

The amount of uncombined hydrogen cyanide at equilibrium was determined by withdrawing a measured volume (the amount suitable having been ascertained by a preliminary titration) and adding to it 10 c.c. of *N*/20-silver nitrate solution, acidified with 2 c.c. of concentrated nitric acid in 20 c.c. of water. The precipitated silver cyanide was filtered off, thoroughly washed with water, and the excess of silver in the filtrate and washings determined by titration with *N*/20-potassium thiocyanate, ferric ammonium sulphate being used as indicator in the light given by a Daylight Electric Bulb, with which readings concordant within 0·04 c.c. were easily obtained. Means of two or more results concordant within 0·06 c.c. were used. The blank experiments were completed in the same way.

In all cases the amount of hydrogen cyanide which had combined with the aldehyde or ketone was determined by difference, for although a direct determination of the combined hydrogen cyanide is possible, it involves serious practical difficulties. In the circumstances, the best evidence that no large error was made in the indirect determination is the consistency in the several values for

* The alcoholic hydrogen cyanide was prepared by dissolving 10 c.c. of anhydrous hydrogen cyanide in 250 c.c. of the alcoholic medium; such a solution contained approximately 10 millimols. of HCN in 10 c.c., and remained unaltered in concentration for several weeks when kept in a stoppered glass flask sealed with paraffin wax.

the equilibrium constant calculated from the different determinations in which the relative quantities of reactants at equilibrium varied considerably.

It is evident that errors arising out of inaccurate measurements of the concentrations entering into the formula for the equilibrium constant are proportionately greatest when any of the three concentrations becomes very small, and this tends to be the case if the cyanohydrin has either a very low or a very high dissociation constant, the former being particularly unfavourable for accuracy. These considerations were always kept in mind while deciding the best ranges of concentration and proportions of constituents to be taken in the series of measurements made with each aldehyde and ketone examined.

Errors arising out of temperature variations may be regarded as relatively very small in the case of ketones; Ultée (*Rec. trav. chim.*, 1909, **28**, 281) showed that the increase in dissociation of the cyanohydrins which he used was less than 5% between 0° and 25°, so that even in some exceptional cases during the present series of measurements where the temperature employed was 18°, the difference was not detectable by the methods employed. With aldehyde-cyanohydrins the temperature coefficient is larger. In view of all the circumstances tending to detract from accuracy, the relative values of the functions in the last column in the tables are usually given to two significant figures only.

A serious source of possible error was impurity in the aldehydes and ketones studied, especially when these were liquids. This error as a rule would be largest when the impurity was chemically inert towards the hydrogen cyanide, for example, any residual alcohol used as solvent in the purification process. The presence of another nearly-related aldehyde or ketone (*e.g.*, an isomeride, in comparing constants for monosubstituted benzaldehydes) was less important, and obviously became less serious the more nearly the properties of the impurity approached those of the main constituent.

Example of Procedure and Calculation.—The case of *p*-chlorobenzaldehyde is selected to illustrate how the several independent values of the dissociation constant of each cyanohydrin were determined with various proportions of the interactants in neutral equilibrium. The total amount of the aldehyde or ketone originally taken was different in each determination, so that, although the total concentration of hydrogen cyanide (*i.e.*, free *plus* combined) was the same in each determination, yet the concentrations of both free aldehyde (or ketone) and hydrogen cyanide at equilibrium were different in each case.

In the example which follows, N_A, N_{HCN}, etc., are the numbers of millimols. of reactant per 50 c.c.; N_A refers to the aldehyde (or ketone) originally taken, and N_{HCN}, N_{R_2CO}, and $N_{R_2C(OH)\cdot CN}$ refer respectively to the *free* hydrogen cyanide, free carbonyl compound, and cyanohydrin found at equilibrium. The number of millimols. of *total* hydrogen cyanide, N_T, was taken as the mean of the two values given in the column N_{HCN} for the two blank experiments, *a* and *b*. Thus

$$N_{R_2C(OH)\cdot CN} = N_T - N_{HCN}, \text{ and } N_{R_2CO} = N_A - N_T + N_{HCN}.$$

The values of K given are the equilibrium constants expressed in the usual units, *viz.*, g.-mols. and litres, and are calculated from the arbitrary values, N_{HCN}, etc., by the relation

$$K = C_{HCN} \times C_{R_2CO}/C_{R_2C(OH)\cdot CN} = 2 \times 10^{-2} \times N_{HCN} \times N_{R_2CO}/N_{R_2C(OH)\cdot CN}.$$

The values of ΔF, in g.-calories, are obtained as usual from the relation $\Delta F = 1{\cdot}99 \times 293 \log_e K$ (for K at 293° abs.). Thus ΔF is zero when $K = 1$, *i.e.*, if cyanohydrin, hydrogen cyanide, and aldehyde or ketone are in equilibrium at normal (unit) concentrations; it is positive or negative accordingly as the dissociation constant of the cyanohydrin is greater or less than unity.

p-Chlorobenzaldehyde.

Expt.	N_A.	N_{HCN}.	N_{R_2CO}.	$N_{R_2C(OH)\cdot CN}$.	$K \times 10^3$.
a	0	8·88	0	0	—

5	11·21	0·66	2·99	8·22	4·80

Mean value of $K = (4{\cdot}94 \pm 0{\cdot}06) \times 10^{-3}$.

The " probable error " or " consistency measure," $\pm 0{\cdot}06 \times 10^{-3}$ (*i.e.*, 1·2% of the mean value), was calculated in the usual way.

Discussion of Results in Table I.

It will be convenient to consider in turn the effects of substituents in the para-, meta-, and ortho-positions.

(1) p-*Substitution.*—When the substituents are arranged in the order of their depressant effects on the affinity of the aldehyde for hydrogen cyanide, beginning with the most effective, the list runs :

Substituent	NMe_2	OH	OCH_3	NO_2	CH_3	Cl and H
$\Delta F \times 10^{-2}$	−5·5	−15·0	−20·0	−23·0	−27·0	−31·0

It will be observed that on this basis the three substituents, NMe_2, OH, and OCH_3, which are characterised by their very large

"quantitative" effects, come first and in their usual order; Cl, however, with its large electropolar effect, takes a position indicating that the effects produced by its quantitative and electropolar factors just balance one another. The authors' views on the appearance of the nitro-group in quite unusual company have already been stated (pp. 2535, 2538).

(2) m-*Substitution*.—Here the sequence among the substituents examined is:

Substituent	CH_3	HO and H	OCH_3	NO_2	Cl
$\Delta F \times 10^{-2}$	−30·0	−31·0	−32·0	−34·0	−35·0

This order bears apparently no relation whatever to the quantitative sequence, but definitely indicates that the electropolar effect is the dominant one. Even the methyl group takes its correct position with respect to hydrogen, although the authors admit that this may be fortuitous, for in this relation, as with that of OCH_3 to H, the difference is approaching the probable limits of experimental error. The order of NO_2 and Cl suggests that possibly NO_2, even in the meta-position, increases the extent of non-polar conjugation (Thiele effect) between the carbonyl group and the nucleus.

It seems highly significant that if the value of the expression $10^{-2} \times (\Delta F_{para} - \Delta F_{meta})$, that is, of $10^{-2} \times (RT \log_e K_{para} - RT \log_e K_{meta})$, be calculated for any of the single-bonded sub-

stituents measured both in para- and in meta-positions, the results obtained are as follows :

Substituent	OH	OCH_3	Cl	CH_3	H
Difference	+16	+12	+4	+3	±0

The agreement with Flürscheim's quantitative sequence (J., 1909, **95**, 726) is remarkable, in spite of the opposite and very widely different electropolar factors of Cl and CH_3. The coincidence cannot fail to suggest that the electropolar effects produced by the substituents are nearly the same at the meta- as at the para-position. If this indeed be so, separation of the quantitative and electropolar factors is greatly simplified.

(3) o-*Substitution.*—The sequence now is :

Substituent	OH	H	OCH_3	Cl	NO_2
$\Delta F \times 10^{-2}$	−24·0	−31·0	−35·0	−40·0	−42·0

The position of OH in this list is almost certainly attributable, not to its quantitative factor, but to the circumstance that *o*-hydroxybenzaldehyde is not comparable with other substituted benzaldehydes, the true hydroxy-compound existing largely as a more stable form where there is chelation between the hydroxyl and carbonyl groups, as Sidgwick and his co-workers have shown (J., 1924, **125**, 527; 1925, **127**, 907). Such an occurrence as this must have the effect of reducing the apparent stability of the cyanohydrin. The other groups, OCH_3, Cl, and NO_2, when in the ortho-position all act so as to increase the stability of the cyanohydrin relatively to that of the aldehyde. In view of the opposite effect which OCH_3 exercises when in the para-position, the large gap between the values of ΔF for ortho-situated OCH_3 and Cl may well be due to the opposite signs of the quantitative factors of these two substituents.

o-Methylbenzaldehyde could not be obtained for examination, but comparison of the numbers found for 2- and for 3-methyl-4-methoxybenzaldehyde show that in the ortho-position, CH_3, like OCH_3, Cl, and NO_2, raises the stability of the cyanohydrin in comparison with that of the aldehyde.

Discussion of Results in Table II.

Here are given a number of dissociation constants for cyanohydrins of cyclic ketones and (in parentheses) of some corresponding open-chain compounds. The effect of ring formation may be roughly shown by subtracting from the value of ΔF for the cyclic ketone that for its open-chain analogue. In the following list the name of the former only is given and the numbers represent the gains

TABLE II.

Constants of Cyanohydrins of some Cyclic (and Related) Ketones.

Ketone.	No. of determinations.	$K \times 10^2$.	% Error.	$\Delta F \times 10^{-2}$.
*cyclo*Pentanone	4	1·49	2·8	−24
(Methyl *n*-propyl ketone)	4	3·54	2·3	−19
*cyclo*Hexanone	4	0·092	4·3	−41
(Methyl *n*-butyl ketone)	4	3·22	1·2	−20
2-Methyl*cyclo*hexanone	5	0·059	5·4	−43
3- ,, ,, ,,	4	0·30	1·1	−34
4- ,, ,, ,,	4	0·127	2·0	−39
Menthone	4	6·54	1·8	−16
*cyclo*Heptanone	4	7·96	1·0	−15
Camphor	(No appreciable cyanohydrin formation.)			>>+10
α-Hydrindone	3	610·0	9·0	+11
(Phenyl ethyl ketone)	5	59·4	1·7	− 3
α-Ketotetrahydronaphthalene	3	806·0	10·0	+10·2
(Phenyl *n*-propyl ketone)	5	89·4	1·2	− 0·65
Fluorenone	3	146·0	0·6	+ 2·3
(Benzophenone)	(No appreciable cyanohydrin formation.)			>>+10
Anthrone and Xanthrone	(No appreciable cyanohydrin formation.)			>>+10

in the free energy of dissociation ($\Delta F \times 10^{-2}$) consequent upon ring closure:

*cyclo*Pentanone	−5·0	α-Hydrindone	+13·5
*cyclo*Hexanone	−20·7	α-Ketotetrahydronaphthalene	+10·9
*cyclo*Heptanone	+*ca.* 6·5	Fluorenone	... very large and negative

In some cases, then, and more especially in those of *cyclo*hexanone and fluorenone, ring formation in effect greatly increases the stability of the addition compound, and, with *cyclo*hexanone and its methyl derivatives, the result is to render the corresponding ketone-cyanohydrins the most stable known. In some cases, on the other hand, ring formation has the opposite result, and this is especially remarkable in the case of α-hydrindone, where ortho-substitution such as is involved in the ring formation would ordinarily tend to stabilise the cyanohydrin.

The effects of introducing methyl groups into *cyclo*hexanone have the appearance of an induced alternate effect, but this can scarcely be more than a coincidence. It seems much more probable that the normal electron-releasing electropolar effect of methyl is larger in the 3- than in the 4-position, whilst in the 2-methyl derivative an electron-restraining effect (similar to that produced by ortho-situated methyl in aromatic acids and aldehydes) enters, dominating all others.

The very large depressant effect of the *iso*propyl group in position 2- in 3-methyl-2-*iso*propylhexanone (menthone) is most striking, for methyl in that position has the opposite effect. Possibly this may be a true case of interference by configurational strain in the

cyanohydrin due to crowding. It has always appeared probable that the so-called steric effects are associated with, and therefore conditioned by, the amount of branching of chains.

Summary.

The constants for the dissociation

$$R^1 \cdot C(OH)(CN) \cdot R^2 \longleftrightarrow R^1 \cdot CO \cdot R^2 + HCN$$

of a number of cyanohydrins derived from aldehydes and ketones have been determined in 96% alcohol at 20° ± 0·5°.

The dissociation constants of cyanohydrins derived from benzaldehyde and its substitution derivatives appear to be affected by the same factors which influence the ionisation constants of benzoic acid and its substitution derivatives (Flürscheim, J., 1909, **95**, 726), although (i) the "electropolar" factor appears to be of relatively less importance in the para-substituted cyanohydrins, and (ii) the "quantitative" factor has little if any influence in the meta-substituted cyanohydrins. The effects of ortho-substituents examined (other than HO) are such as to depress the dissociation constants of the cyanohydrin, and this is in direct contrast to the result to be anticipated from the classical "space-occupation" hypothesis so frequently used to account for other effects associated with ortho-substitution. Ring closure (with elimination of two atoms of hydrogen) in a chain comprising a carbonyl carbon atom leads sometimes to a large increase and sometimes to a large decrease in the dissociation constant of the derived cyanohydrin.

The results obtained are discussed from the point of view of the electronic theory, and it is suggested that possibly the additive capacity of carbonyl carbon and ethylenic carbon, considered from the standpoint of entropy, does not increase continuously with the restraint on its electrons but reaches a maximum and then declines, just as in the series, boron, carbon, nitrogen, and oxygen, the capacity to form stable compounds, in which the element exercises a co-ordination number of 4, attains a maximum at carbon.

The authors gratefully acknowledge that a considerable part of the cost of the materials used for this work was defrayed from the Brunner Mond Research Fund.

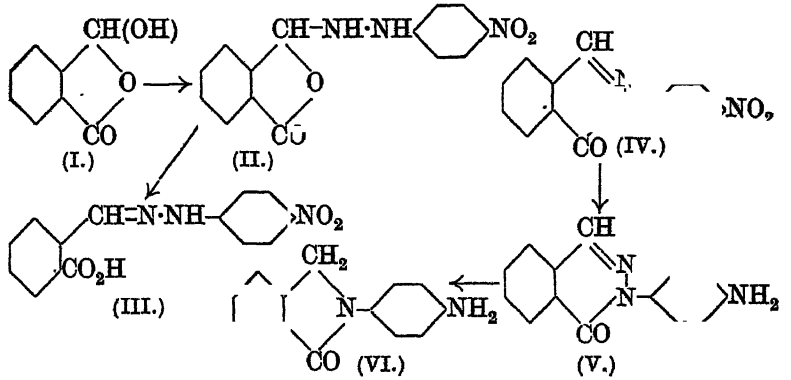
CCCXXXVII.—*A New Reaction of Certain Diazosulphonates derived from β-Naphthol-1-sulphonic Acid. Part II. The Constitution of Nitro- and Amino-phenylphthalazones.*

By FREDERICK MAURICE ROWE and ESTHER LEVIN.

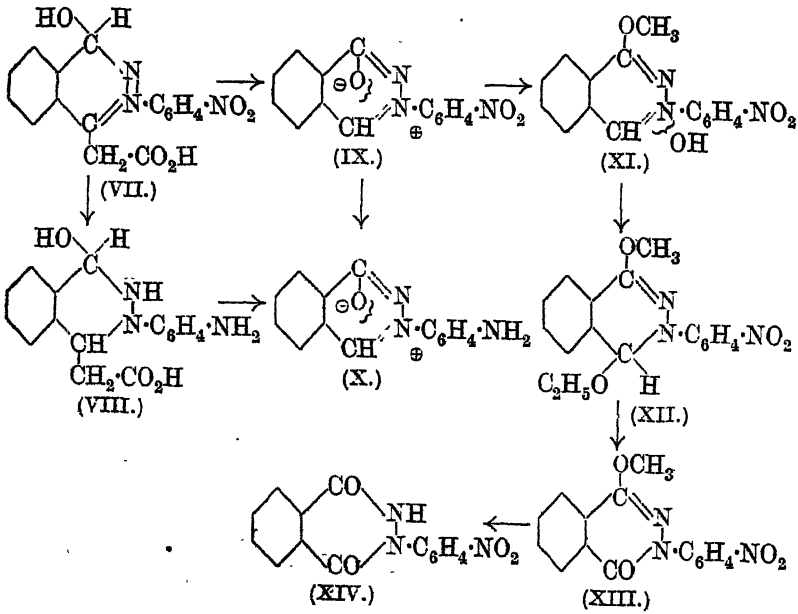


IN a former communication (J., 1926, 700) we stated that 1-hydroxy-3-(4′-nitrophenyl)-1 : 3-dihydrophthalazine-4-acetic acid (VII) is reprecipitated unaltered by diluting a solution in cold concentrated sulphuric acid, but boiling with aqueous sulphuric acid gives a substance which is not precipitated from the solution on further dilution. The latter substance has now been examined more closely. Acetic acid is eliminated during the reaction, and analysis of the product, yellow needles, m. p. 333°, gave the formula $C_{14}H_9O_3N_3$, which is that of a nitrophenylphthalazone. Consequently, this reaction is analogous to the conversion of 1-hydroxy-3-(4′-aminophenyl)-tetrahydrophthalazine-4-acetic acid (VIII) into an aminophenylphthalazone by boiling with aqueous mineral acid (*loc. cit.*, p. 703). The product obtained by the reduction of the nitrophenylphthalazone varies with the conditions used. Thus, reduction with aqueous sodium sulphide gives the aminophenylphthalazone, which we described previously as 4′-amino-3-phenylphthalaz-4-one, whereas zinc dust and hydrochloric acid give 4′-amino-*N*-phenylphthalimidine.

Seekles (*Rec. trav. chim.*, 1924, **43**, 329) has described as a nitrophenylphthalazone a substance, deep orange needles, becoming paler at 228° and melting at 259°, which he obtained by condensing *o*-phthalaldehydic acid with *p*-nitrophenylhydrazine in alcoholic solution. This compound obviously is not identical with ours, and its method of preparation should lead to 4′-nitro-3-phenylphthalaz-4-one. If that is the case, our compound is the isomeric 4′-*nitro*-3-*phenylphthalaz*-1-*one* (IX), and the compound which we described previously as 4′-amino-3-phenylphthalaz-4-one is actually 4′-*amino*-3-*phenylphthalaz*-1-*one* (X). Consequently, in converting 1-hydroxy-3-(4′-aminophenyl)tetrahydrophthalazine-4-acetic acid into the aminophenylphthalazone with elimination of acetic acid, it is not the $>CH\cdot CH_2\cdot CO_2H$ group, but the $>CH\cdot OH$ group, which is converted into a keto-group.

Unsuccessful attempts were made to confirm this hypothesis by eliminating the amino-group from our aminophenylphthalazone, so that the corresponding phenylphthalazone could be compared with 3-phenylphthalaz-4-one (Racine, *Annalen*, 1887, **239**, 86; Thiele and Falk, *ibid.*, 1906, **347**, 112), of which the constitution is

definitely known. Diazotisation and boiling with alcohol under a variety of conditions, or diazotisation, and reduction of the diazonium compound to the hydrazine, followed by oxidation with copper acetate, gave no phenylphthalazone. In the latter case, disruption of the molecule undoubtedly occurred.



It appeared desirable, therefore, to prepare Seekles's compound for purposes of comparison, and, as a result, it was found not to be a nitrophenylphthalazone. The condensation of an equimolecular proportion of phthalaldehydic acid and *p*-nitrophenylhydrazine in boiling alcoholic solution gives the compound described by Seekles, but it has the formula $C_{14}H_{11}O_4N_3$ and is actually only an intermediate stage in the formation of the nitrophenylphthalazone. In alcoholic solution, phthalaldehydic acid reacts mainly in the tautomeric form of hydroxyphthalide (I), and under these conditions condensation is limited to formation of the lactone form of o-*carboxybenzaldehyde*-p-*nitrophenylhydrazone* (II), which Seekles described as a nitrophenylphthalazone. This condensation product dissolves in sodium carbonate owing to conversion into the free *acid* (III), but on boiling a nitrobenzene solution a molecule of water is eliminated and gives the actual 4′-*nitro*-3-*phenylphthalaz*-4-*one* (IV), colourless needles, m. p. 258°, which is isomeric and not identical with the nitrophenylphthalazone we have obtained from 1-hydroxy-3-(4′-nitrophenyl)-1 : 3-dihydrophthalazine-4-acetic acid.

4′-Nitro-3-phenylphthalaz-4-one, although sparingly soluble in mineral acids, does not form salts with them and is insoluble in sodium hydroxide. Reduction with sodium sulphide gives the actual 4′-*amino*-3-*phenylphthalaz*-4-*one* (V), and reduction with zinc dust and hydrochloric acid gives 4-′amino-*N*-phenylphthalimidine (VI), but the conversion into the latter does not proceed so readily as in the case of 4′-nitro-3-phenylphthalaz-1-one.

The formula (IX) for 4′-*nitro*-3-*phenylphthalaz*-1-*one* appears to

agree best with its properties. Thus, it is acidic and dissolves readily in sodium hydroxide with a bluish-red colour; also it is basic and dissolves readily in mineral acids, forming well-crystallised salts, decomposed by water; and it forms a *picrate*. Further, it would be anticipated that the oxygen atom of the keto-group in a compound of this constitution could be methylated, and this proved to be the case, although the course of the reaction was somewhat complicated. The product of the interaction of 4′-nitro-3-phenylphthalaz-1-one with methyl sulphate in nitrobenzene solution, after removal of the latter, is obtained as an aqueous solution of the *methosulphate*, and is isolated as an orange-yellow, amorphous powder by making alkaline with sodium carbonate. This *substance*, probably (XI), crystallises well from alcohol, but it combines with the alcohol, probably forming (XII), and is then so reactive that it was impossible to determine its formula analytically. This proved to be immaterial, however, for by heating the compound after crystallisation from alcohol first at 110° and then at 140° it is readily converted into 4-*keto*-1-*methoxy*-3-(4′-*nitrophenyl*)-3 : 4-*dihydrophthalazine* (XIII), which is neither acidic nor basic. This compound is demethylated by heating with hydrobromic acid and glacial acetic acid in a sealed tube at 100° with formation of 1 : 4-*diketo*-3-(4′-*nitrophenyl*)*tetrahydrophthalazine* (XIV).

On the other hand, 4′-nitro-3-phenylphthalaz-4-one is neither

acidic nor basic, it does not form a picrate, and is unaltered by treatment with methyl sulphate under conditions identical with those used in the case of 4′-nitro-3-phenylphthalaz-1-one.

EXPERIMENTAL.

4′-Nitro-3-phenylphthalaz-1-one (IX).—A mixture of 10 g. of finely-powdered 1-hydroxy-3-(4′-nitrophenyl)-1 : 3-dihydrophthalazine-4-acetic acid (VII), 50 c.c. of concentrated sulphuric acid, and 60 c.c. of water was boiled (b. p. 140°) under reflux. Solution was complete after ½ hour, and boiling was continued for a further 1½ hours, acetic acid being eliminated during the reaction. The mixture was cooled, diluted with 240 c.c. of water, boiled, and filtered. After cooling, the sulphate, colourless needles, was filtered off and neutralised with sodium carbonate. A further quantity, but less pure, was isolated by neutralising the filtrate. The united product was purified through the sparingly soluble hydrochloride, long, colourless needles, and, after neutralisation with sodium carbonate, the *base* crystallised from pyridine in fine yellow needles, m. p. 333° (not 331° as previously given) (yield 5·6 g.; 68·5%) (Found: C, 62·9; H, 3·5; N, 15·7. $C_{14}H_9O_3N_3$ requires C, 62·9; H, 3·4; N, 15·7%). The substance is readily soluble in glacial acetic acid, soluble in nitrobenzene, sparingly soluble in alcohol and ethyl acetate, and very sparingly soluble in benzene. It is insoluble in sodium carbonate, but dissolves in sodium hydroxide with a bluish-red colour, changing to orange-brown on keeping; with mineral acids it forms salts which are readily decomposed by water. With an alcoholic solution of picric acid it forms a *picrate*, fine bright yellow needles, m. p. 218°, which appear to be decomposed progressively by recrystallisation from alcohol (Found: C, 48·6; H, 2·5. $C_{20}H_{12}O_{10}N_6$ requires C, 48·4; H, 2·4%).

Reduction of 4′-Nitro-3-phenylphthalaz-1-one.—(*a*) A fine suspension of 2 g. of 4′-nitro-3-phenylphthalaz-1-one in 50 c.c. of water was heated to 50° with a solution of 16 g. of sodium sulphide crystals in 15 c.c. of water. The bluish-red colour of the solution changed to reddish-orange, and orange-coloured needles separated. The mixture was then boiled for 10 minutes, cooled, and filtered. The *4′-amino-3-phenylphthalaz-1-one* (X) crystallised from alcohol in deep straw-coloured, prismatic needles, m. p. 259° (yield 1 g.; 56%), and is identical with the compound which we described formerly as 4′-amino-3-phenylphthalaz-4-one. (*b*) A solution of 2 g. of 4′-nitro-3-phenylphthalaz-1-one in 50 c.c. of water and 75 c.c. of concentrated hydrochloric acid was boiled, and 4 g. of zinc dust were added gradually with vigorous boiling. The 4′-amino-*N*-phenylphthalimidine (VI), almost colourless, prismatic needles,

m. p. 198° (yield 1·3 g.; 77%), was isolated as previously described (*loc. cit.*, p. 704).

Action of Methyl Sulphate on 4'-Nitro-3-phenylphthalaz-1-one.—A solution of 5 g. of 4'-nitro-3-phenylphthalaz-1-one in 120 c.c. of boiling, dry nitrobenzene was cooled to about 140°, and 2·5 g. of methyl sulphate were added to the crystalline mixture. The crystals disappeared rapidly and the reaction was completed by heating under reflux at 150° for ½ hour. Nitrobenzene was removed by distillation with steam, and the aqueous residue, after filtering from a little resin, gave an orange-yellow, flocculent precipitate when rendered alkaline with sodium carbonate. This *substance* (XI) forms a hydrochloride, stout colourless needles, and is unaltered by prolonged boiling with hydrochloric acid; it is insoluble in cold alkalis, but is decomposed by boiling with sodium hydroxide. On addition of alcohol to the dry compound, it became resinous and then crystalline, and after crystallising four times from ethyl alcohol formed large, orange, elongated, hexagonal prisms (XII), m. p. 138—141° (Found: C, 63·3; H, 5·7; N, 13·6; total OR, calculated as OMe, 18·3%). On the other hand, crystallisation from methyl alcohol gave orange leaflets and diamond-shaped crystals, m. p. 173—175° (Found: C, 62·3; H, 5·1; OMe, 18·5%). No definite conclusions as to the composition of these compounds after crystallisation from methyl or ethyl alcohol could be based on these analyses, however, because the substance has combined with the alcohols and the products are decomposed partially even by drying in a vacuum at the ordinary temperature, as was done for the preparation of the analytical specimens, whilst at 100° the crystals become opaque and are converted gradually into 4-keto-1-methoxy-3-(4'-nitrophenyl)-3 : 4-dihydrophthalazine (XIII). The latter change was best effected by heating first at 100° and then at 140°.

4-Keto-1-methoxy-3-(4'-nitrophenyl)-3 : 4-dihydrophthalazine crystallised from alcohol in fine pale yellow needles, or from glacial acetic acid in colourless needles, m. p. 199° (Found: C, 60·9; H, 3·9; N, 14·3; OMe, 10·3. $C_{15}H_{11}O_4N_3$ requires C, 60·6; H, 3·7; N, 14·1; OMe, 10·4%). The substance is readily soluble in chloroform, ethyl acetate and toluene, but insoluble in dilute mineral acids or alkalis. When 1 g. was heated with glacial acetic acid and twice the volume of hydrobromic acid in a sealed tube at 100° for about 10 minutes, *1 : 4-diketo-3-(4'-nitrophenyl)tetrahydrophthalazine* (XIV) separated, and after recrystallisation from glacial acetic acid, formed colourless needles, m. p. 307° (Found: C, 59·5; H, 3·4; N, 15·0. $C_{14}H_9O_4N_3$ requires C, 59·4; H, 3·2; N, 14·8%), insoluble in dilute mineral acids, but soluble in dilute sodium carbonate, giving a pale yellow colour.

4'-Nitro-3-phenylphthalaz-4-one (IV).—A mixture of a solution of 4·5 g. of *o*-phthalaldehydic acid in 100 c.c. of alcohol and a solution of 4·6 g. of *p*-nitrophenylhydrazine in 80 c.c. of alcohol was boiled under reflux for about 5 minutes after the lactone form of *o-carboxybenzaldehyde-p-nitrophenylhydrazone* (II) had separated in orange needles, m. p. 254° after shrinking and becoming paler at 228° (Found: C, 58·6; H, 4·0; N, 14·9. $C_{14}H_{11}O_4N_3$ requires C, 58·9; H, 3·9; N, 14·7%). It is sparingly soluble in dilute hydrochloric acid and soluble in dilute sodium carbonate owing to opening of the ring with formation of *o-carboxybenzaldehyde-p-nitrophenylhydrazone* (III), which is precipitated on acidifying the alkaline solution as a red powder, decomposing at 218° and then melting at 249°. Attempts to recrystallise the lactone form from alcohol or pyridine resulted in its conversion into *4'-nitro-3-phenylphthalaz-4-one*. The latter compound was prepared most conveniently by boiling a nitrobenzene solution for a short time; after cooling, it crystallised in long, colourless, glistening needles, m. p. 258° (Found: C, 63·0; H, 3·4; N, 15·7. $C_{14}H_9O_3N_3$ requires C, 62·9; H, 3·4; N, 15·7%). It is almost insoluble in alcohol, insoluble in sodium carbonate or hydroxide, but very sparingly soluble in hydrochloric acid. It neither forms a picrate nor reacts with methyl sulphate.

4'-Amino-3-phenylphthalaz-4-one (V).—A fine suspension of 2 g. of the lactone in 50 c.c. of water was heated to 50° with a solution of 16 g. of sodium sulphide crystals in 15 c.c. of water. The bluish-red colour of the solution changed to orange-yellow, and on further heating, almost colourless crystals separated in small yield. The *4'-amino-3-phenylphthalaz-4-one* crystallised from alcohol or water in long, pale yellow needles, m. p. 184° (Found: C, 70·7; H, 4·7; N, 17·9. $C_{14}H_{11}ON_3$ requires C, 70·9; H, 4·6; N, 17·7%). It is soluble in hot water, insoluble in alkalis, but soluble in dilute acids (*hydrochloride*, colourless needles), and can be diazotised. A solution of 1 g. in 10 c.c. of glacial acetic acid was boiled with 0·2 c.c. of acetic anhydride for 2 hours and poured into water; the *acetyl* derivative crystallised from dilute alcohol in colourless, feathery needles, m. p. 233° (Found: N, 15·0. $C_{16}H_{13}O_2N_3$ requires N, 15·0%). Reduction of the lactone form with zinc dust and hydrochloric acid, as described on p. 2553, resulted also in the formation of 4'-amino-*N*-phenylphthalimidine (VI), almost colourless needles, m. p. 198°, although with greater difficulty and in much lower yield.

We desire to thank Professor Robert Robinson, F.R.S., for his continued interest in this series of investigations.

LEEDS UNIVERSITY. [*Received, June 26th, 1928.*]

CCCXXXVIII.—*A New Reaction of Certain Diazosulphonates derived from β-Naphthol-1-sulphonic Acid. Part III. Preparation of Phthalazine, Phthalazone, and Phthalimidine Derivatives from* m-*Nitroaniline.*

By FREDERICK MAURICE ROWE, MAHMED AHMED HIMMAT, and ESTHER LEVIN.

IN Parts I and II of this series (J., 1926, 690; preceding paper), the preparation of phthalazine, phthalazone, and phthalimidine derivatives from 4′-nitrobenzene-2-naphthol-1-diazosulphonate has been described, and the constitution of the isomeric 4′-nitro- and -amino-phenylphthalazones discussed. The investigation has now been extended to the corresponding 3′-nitro- and amino-derivatives.

3′-Nitrobenzene-2-naphthol-1-diazosulphonate is formed quantitatively from diazotised *m*-nitroaniline and β-naphthol-1-sulphonic acid in acid solution, but conversion through *sodium* 1-3′-*nitrobenzeneazo*-β-*naphthaquinone*-1-*sulphonate* into *sodium hydrogen* 3-(3′-*nitrophenyl*)-1 : 3-*dihydrophthalazine*-4-*acetic acid*-1-*sulphonate* is accompanied by no marked change in colour and does not proceed so readily as in the case of the 4′-nitro-isomeride, owing to an increased tendency to the formation of 3′-nitrobenzeneazo-β-naphthol in appreciable quantities. This side reaction is limited by working at greater dilution, but under the best conditions the yield is 15% less than that obtained with the 4′-nitro-isomeride. Monosodium 3-(3′-nitrophenyl)-1 : 3-dihydrophthalazine-4-acetic acid-1-sulphonate resembles the 4′-nitro-isomeride in general properties, although it is noteworthy that, whereas the latter is a level-dyeing, pure greenish-yellow, acid dye of good tinctorial power, the former possesses hardly any tinctorial properties. The replacement of the sodium-1-sulphonate group by hydroxyl gives 1-*hydroxy*-3-(3′-*nitrophenyl*)-1 : 3-*dihydrophthalazine*-4-*acetic acid* in a yield of about 10% less than was obtained with the 4′-nitro-isomeride. *Esters* and an *anilide* of this hydroxy-compound were obtained readily, but attempts to prepare an acetyl derivative failed, for although a variety of conditions was employed the product was always resinous and could not be crystallised. Unlike the 4′-nitro-isomeride, 1-hydroxy-3-(3′-nitrophenyl)-1 : 3-dihydrophthalazine-4-acetic acid is not reduced satisfactorily by alkaline hydrosulphite [hyposulphite], for the compounds in the present series appear to be more sensitive to alkalis, and although the product resembled that anticipated in appearance and solubility in acids and alkalis, it could

not be purified by crystallisation and was not converted into the corresponding aminophenylphthalazone by boiling with mineral acid. 1-*Hydroxy*-3-(3′-*aminophenyl*)*tetrahydrophthalazine*-4-*acetic acid* is obtained satisfactorily, however, by reduction with stannous chloride and hydrochloric acid, because its hydrochloride is so sparingly soluble in concentrated hydrochloric acid that the reaction does not proceed further even after prolonged boiling. On the other hand, by boiling 1-hydroxy-3-(3′-aminophenyl)tetrahydrophthalazine-4-acetic acid with aqueous sulphuric acid (b. p. 140°), acetic acid is eliminated and 3′-*amino*-3-*phenylphthalaz*-1-*one* is obtained in a 91% yield. When this is reduced with zinc dust and hydrochloric acid, one nitrogen atom is eliminated as ammonia and 3′-*amino*-N-*phenylphthalimidine* is produced. The replacement of the amino-group in the latter by hydrogen or by hydroxyl proceeds as with the 4′-amino-isomeride, except that, as the diazonium chloride obtained from 3′-amino-*N*-phenylphthalimidine is less stable to the action of boiling dilute sulphuric acid, 3′-*hydroxy*-N-*phenylphthalimidine* is formed with greater ease.

When 1-hydroxy-3-(3′-nitrophenyl)-1 : 3-dihydrophthalazine-4-acetic acid is boiled with sulphuric acid (b. p. 140°), it loses acetic acid and 3′-*nitro*-3-*phenylphthalaz*-1-*one* is formed, but in a yield of 12% less than was obtained with the 4′-nitro-isomeride. 3′-Nitro-3-phenylphthalaz-1-one is much less acidic than the latter, but with mineral acids it also forms well-crystallised salts, decomposed by water, and it forms a more stable *picrate*. The product obtained from it by reduction varies with the conditions used. Thus, reduction with aqueous sodium sulphide gives 3′-amino-3-phenylphthalaz-1-one, although in a yield of 17% less than was obtained by the action of aqueous sulphuric acid on 1-hydroxy-3-(3′-aminophenyl)tetrahydrophthalazine-4-acetic acid, whereas zinc dust and hydrochloric acid give 3′-amino-*N*-phenylphthalimidine. 3′-Nitro-3-phenylphthalaz-1-one reacts with methyl sulphate in a similar manner to the 4′-nitro-isomeride, and the primary product behaves similarly with methyl or ethyl alcohol. After crystallisation from alcohol, heating gives 4-*keto*-1-*methoxy*-3-(3′-*nitrophenyl*)-3 : 4-*dihydrophthalazine*, but this is always accompanied by a more complex substance, especially if heating is too rapid at first. 1 : 4-*Diketo*-3-(3′-*nitrophenyl*)*tetrahydrophthalazine* is obtained from the methoxy-compound by the action of hydrobromic acid.

Finally, 3′-*nitro*-3-*phenylphthalaz*-4-*one* was prepared for purposes of comparison. The condensation of equimolecular proportions of phthalaldehydic acid and *m*-nitrophenylhydrazine in boiling alcoholic solution gives the *lactone* form of the *m*-nitrophenylhydrazone, and when a nitrobenzene solution of this is boiled, a molecule of water is

eliminated with formation of 3′-nitro-3-phenylphthalaz-4-one. The latter, although very sparingly soluble in mineral acids, does not form salts either with them or with picric acid, is insoluble in sodium hydroxide, and is unaltered by treatment with methyl sulphate under conditions identical with those used in the case of 3′-nitro-3-phenylphthalaz-1-one.

The lactone form of *o*-carboxybenzaldehyde-*p*-nitrophenylhydrazone is converted into 4′-amino-3-phenylphthalaz-4-one by treatment with warm aqueous sodium sulphide, but the corresponding *m*-nitro-derivative is merely converted into 3′-nitro-3-phenylphthalaz-4-one, which separates and remains unaltered even after prolonged boiling. 3′-*Amino*-3-*phenylphthalaz*-4-*one*, however, is readily obtained by reducing 3′-nitro-3-phenylphthalaz-4-one with alkaline hydrosulphite.

Further work on this subject is in progress.

EXPERIMENTAL.

Sodium Hydrogen 3-(3′-*Nitrophenyl*)-1 : 3-*dihydrophthalazine*-4-*acetate*-1-*sulphonate*.—A filtered solution of 50 g. of commercial sodium β-naphthol-1-sulphonate in 220 c.c. of water was stirred into a cold solution of diazotised *m*-nitroaniline, obtained by adding a concentrated solution of 14 g. of sodium nitrite to a solution of 24 g. of *m*-nitroaniline in 60 c.c. of concentrated hydrochloric acid and 180 c.c. of water. The 3′-nitrobenzene-2-naphthol-1-diazosulphonate separated immediately as a yellowish-brown precipitate in theoretical yield (calculated on the *m*-nitroaniline). This was filtered off, washed free from acid with brine, made into a paste with 600 c.c. of cold water, and a cold solution of 50 g. of anhydrous sodium carbonate in 250 c.c. of water was added. The *sodium* 1-3′-*nitrobenzeneazo*-β-*naphthaquinone*-1-*sulphonate* formed does not separate from the solution at this dilution. The cold, clear, yellowish-brown solution was added immediately to a cold solution of 60 g. of sodium hydroxide in 120 c.c. of water, the temperature rose about 10°, and the deep reddish-brown mixture was left overnight. Conversion into sodium 3-(3′-nitrophenyl)-1 : 3-dihydrophthalazine-4-acetic acid-1-sulphonate was accompanied by little change in colour. The mixture was rendered faintly acid with hydrochloric acid, then made alkaline with sodium carbonate, and a small amount of 3′-nitrobenzeneazo-β-naphthol (Metanitraniline Orange) filtered off. The latter should not be washed with hot water, as this renders the product resinous and difficult to coagulate. The filtrate was rendered faintly acid with hydrochloric acid, and salt added cautiously until the monosodium salt of the product separated completely as a yellowish-brown, semi-crystalline precipitate.

After drying, the product was separated from sodium chloride by extraction with absolute alcohol, from which it crystallised in orange-yellow prisms (yield 55 g.; 76·3%) (Found: S, 7·7. $C_{16}H_{12}O_7N_3SNa$ requires S, 7·7%). It is readily soluble in water, but less soluble in alcohol, forming yellow solutions, which are deepened in colour by the addition of alkalis. The aqueous solution is decolorised by zinc dust and ammonia, and on exposure to air a deeper colour returns. Unlike the 4′-nitro-isomeride (J., 1926, 699), it possesses but little tinctorial power.

1-*Hydroxy*-3-(3′-*nitrophenyl*)-1 : 3-*dihydrophthalazine*-4-*acetic Acid.*—An aqueous solution of monosodium-3-(3′-nitrophenyl)-1 : 3-dihydrophthalazine-4-acetic acid-1-sulphonate (32 g.) was boiled with concentrated hydrochloric acid (aqueous sulphuric acid also can be used) as described for the 4′-nitro-isomeride (*ibid.*, p. 700). The product crystallised from ethyl acetate in pale yellow, prismatic needles, m. p. 234° (yield 21·3 g.; 83·5%) (Found: C, 58·9; H, 4·0; N, 12·9. $C_{16}H_{13}O_5N_3$ requires C, 58·7; H, 4·0; N, 12·8%). The substance is readily soluble in alcohol or glacial acetic acid, but less soluble in benzene, acetone, or ether. It is sparingly soluble in water, forming a solution acid to litmus, but dissolves readily in sodium carbonate with an orange-yellow colour, or in sodium hydroxide with a deep reddish-brown colour. It dissolves in cold concentrated sulphuric acid with a yellow colour and is reprecipitated unaltered on dilution, but when boiled with aqueous sulphuric acid it is converted into 3′-nitro-3-phenylphthalaz-1-one.

Derivatives of 1-*Hydroxy*-3-(3′-*nitrophenyl*)-1 : 3-*dihydrophthalazine*-4-*acetic Acid.*—The *methyl* ester, prepared as described for the 4′-nitro-isomeride (*ibid.*, p. 700), crystallised from methyl alcohol in pale yellow needles, m. p. 184° (Found: C, 59·7; H, 4·5; N, 12·2. $C_{17}H_{15}O_5N_3$ requires C, 59·8; H, 4·4; N, 12·3%). The *ethyl* ester, similarly prepared, crystallised from ethyl alcohol in pale yellow needles, m. p. 195° (Found: C, 61·1; H, 5·0; N, 11·9. $C_{18}H_{17}O_5N_3$ requires C, 60·8; H, 4·8; N, 11·8%). It is insoluble in sodium carbonate, but dissolves in sodium hydroxide with a reddish-brown colour. The *anilide* was prepared as described for the 4′-nitro-isomeride and, after several crystallisations from ethyl acetate, formed transparent, yellow prisms, m. p. 239° (decomp.) (Found: C, 65·8; H, 4·8; N, 13·9. $C_{22}H_{18}O_4N_4$ requires C, 65·7; H, 4·5; N, 13·9%). It is almost insoluble in cold sodium hydroxide, whereas the 4′-nitro-isomeride is readily soluble with a red colour, and it is also hydrolysed to the original acid by boiling concentrated hydrochloric acid.

1-*Hydroxy*-3-(3′-*aminophenyl*)*tetrahydrophthalazine*-4-*acetic Acid.*—1-Hydroxy-3-(3′-nitrophenyl)-1 : 3-dihydrophthalazine-4-acetic acid

(20 g.) was boiled under reflux with a solution of stannous chloride (80 g.) in concentrated hydrochloric acid (200 c.c.) until it had all dissolved and been replaced by the hydrochloride of 1-hydroxy-3-(3′-aminophenyl)tetrahydrophthalazine-4-acetic acid, colourless cubic crystals. After a further 10 minutes' boiling, the hydrochloride was filtered off, washed with cold concentrated hydrochloric acid, and dissolved in water; tin was removed from the solution by means of hydrogen sulphide, and the product isolated by adding sodium carbonate until a white precipitate had separated completely. After being washed with cold water, it crystallised from boiling water in almost colourless, glistening prisms, m. p. 252° (yield 15·7 g.; 86%) (Found: C, 64·4; H, 5·4; N, 14·2. $C_{16}H_{17}O_3N_3$ requires C, 64·2; H, 5·7; N, 14·0%). This compound cannot be obtained satisfactorily by reduction with alkaline hydrosulphite. It is sparingly soluble in alcohol and benzene, more soluble in water than the 4′-amino-isomeride, and, unlike the latter, gives no coloration with ferric chloride. It dissolves readily in dilute alkalis or dilute acids, and can be diazotised. Direct esterification in this case also proved unsatisfactory, but there was no difficulty in preparing a pure *acetyl* derivative, which crystallised from boiling water in colourless prisms, m. p. 167° (Found: C, 63·5; H, 5·5; N, 12·1. $C_{18}H_{19}O_4N_3$ requires C, 63·3; H, 5·6; N, 12·3%).

3′-*Amino*-3-*phenylphthalaz*-1-*one*.—A solution of 5 g. of 1-hydroxy-3-(3′-aminophenyl)tetrahydrophthalazine-4-acetic acid in a mixture of 25 c.c. of concentrated sulphuric acid and 30 c.c. of water was boiled (b. p. 140°) under reflux for 1½ hours, acetic acid being eliminated during the reaction. After cooling, the solution was diluted with 50 c.c. of water, neutralised with sodium hydroxide, then made distinctly alkaline with sodium carbonate and filtered. The base crystallised from alcohol in stout, golden-yellow, spear-shaped prisms, m. p. 210° (yield 3·6 g.; 91%) (Found: C, 71·1; H, 4·8; N, 17·8. $C_{14}H_{11}ON_3$ requires C, 70·9; H, 4·6; N, 17·7%). It is soluble in hot water, sparingly soluble in acetone, and insoluble in benzene. It is insoluble in alkalis, but soluble in dilute acids and can be diazotised; the hydrochloride formed colourless needles, and the *acetyl* derivative crystallised from boiling water in fine, colourless needles, m. p. 204° (Found: C, 68·7; H, 4·9; N, 14·8. $C_{16}H_{13}O_2N_3$ requires C, 68·8; H, 4·7; N, 15·0%).

3′-*Amino*-N-*phenylphthalimidine*.—3′-Amino-3-phenylphthalaz-1-one was reduced with zinc dust and hydrochloric acid as described for the 4′-amino-isomeride (*loc. cit.*). After cooling, the product separated completely as colourless plates of the hydrochloride, together with a small proportion of colourless needles of the *zinc*

double chloride; the filtrate contained ammonia. The crystals were dissolved in a little hot water and hydrochloric acid, the solution was rendered alkaline, and the dry precipitate extracted with alcohol. The base crystallised in almost colourless prismatic needles, m. p. 175° (Found: C, 75·1; H, 5·7; N, 12·8. $C_{14}H_{12}ON_2$ requires C, 75·0; H, 5·4; N, 12·5%). The *acetyl* derivative crystallised from alcohol in colourless, silky needles, m. p. 204° (Found: C, 71·9; H, 5·6; N, 10·6. $C_{16}H_{14}O_2N_2$ requires C, 72·2; H, 5·4; N, 10·5%). *N*-Phenylphthalimidine, almost colourless plates, m. p. 160°, was obtained by diazotising 3′-amino-*N*-phenylphthalimidine sulphate, and boiling the sparingly soluble diazonium sulphate (almost colourless needles) with alcohol.

3′-*Hydroxy*-N-*phenylphthalimidine*.—This compound was prepared from 3′-amino-*N*-phenylphthalimidine (10 g.) as described for the 4′-hydroxy-isomeride (*loc. cit.*, p. 704), except that, as the diazo-compound in the present case was less stable, boiling for longer than ½ hour was unnecessary. The hydroxy-derivative crystallised from alcohol in colourless glistening leaflets, m. p. 268° (yield 9·5 g.; 95%) (Found: C, 75·0; H, 5·0; N, 6·4. $C_{14}H_{11}O_2N$ requires C, 74·7; H, 4·9; N, 6·2%). Its *methyl* ether, m. p. 122° (Found: C, 75·0; H, 5·5; N, 6·0. $C_{15}H_{13}O_2N$ requires C, 75·3; H, 5·4; N, 5·9%), and *ethyl* ether, m. p. 115° (Found: C, 75·7; H, 5·9; N, 5·6. $C_{16}H_{15}O_2N$ requires C, 75·9; H, 5·9; N, 5·5%), crystallised from the corresponding alcohols in colourless leaflets.

3′-*Nitro*-3-*phenylphthalaz*-1-*one*.—A solution of 5 g. of 1-hydroxy-3-(3′-nitrophenyl)-1 : 3-dihydrophthalazine-4-acetic acid in 25 c.c. of concentrated sulphuric acid was diluted with 30 c.c. of water, and the mixture boiled (b. p. 140°) under reflux. Solution was complete after ¾ hour, and boiling was continued for a further ¾ hour, acetic acid being eliminated during the reaction. The mixture was cooled, diluted with 120 c.c. of water, boiled, and filtered. After cooling, the sulphate (colourless needles) was filtered off and neutralised with sodium carbonate. A further quantity was isolated by neutralising the filtrate. The united product was purified through the sparingly soluble hydrochloride (long, colourless needles), and, after neutralisation with sodium carbonate, crystallised from pyridine in pale yellow needles, m. p. 324° (yield 2·3 g.; 56·5%) (Found: C, 63·2; H, 3·5; N, 15·7. $C_{14}H_9O_3N_3$ requires C, 62·9; H, 3·4; H, 15·7%). The substance is readily soluble in glacial acetic acid, soluble in nitrobenzene, sparingly soluble in alcohol and ethyl acetate, and very sparingly soluble in benzene. It is insoluble in sodium carbonate, and very sparingly soluble in boiling sodium hydroxide with a faint orange colour; with mineral acids it forms

salts, which are readily decomposed by water. With an alcoholic solution of picric acid it forms a *picrate*, bright yellow needles, m. p. 234°, which can be recrystallised from alcohol without decomposition (Found: C, 48·6; H, 2·6; N, 16·8. $C_{20}H_{12}O_{10}N_6$ requires C, 48·4; H, 2·4; N, 16·9%).

Reduction of 3'-Nitro-3-phenylphthalaz-1-one.—(*a*) Reduction of 3'-nitro-3-phenylphthalaz-1-one (5 g.) with aqueous sodium sulphide as described for the 4'-nitro-isomeride (this vol., p. 2553) gave 3'-amino-3-phenylphthalaz-1-one (yield 3·3 g.; 74%), identical with that obtained from 1-hydroxy-3-(3'-aminophenyl)tetrahydrophthalazine-4-acetic acid (p. 2560).

(*b*) Reduction with zinc dust and hydrochloric acid gave 3'-amino-*N*-phenylphthalimidine (yield 83%), identical with that obtained from 3'-amino-3-phenylphthalaz-1-one (p. 2560).

Action of Methyl Sulphate on 3'-Nitro-3-phenylphthalaz-1-one.—A solution of 3'-nitro-3-phenylphthalaz-1-one in nitrobenzene was treated with methyl sulphate as described for the 4'-nitro-isomeride (*loc. cit.*), and the nitrobenzene removed by distillation with steam. The aqueous residue, after being filtered from a little resin, gave an orange-yellow, flocculent precipitate when rendered alkaline with sodium carbonate. This basic substance behaves with alcohol in a similar manner to the 4'-nitro-isomeride, becoming first resinous and then crystalline. Thus, crystallisation from methyl alcohol gave golden-yellow needles, m. p. 114—117° (Found: OMe, 18·5%), and crystallisation from ethyl alcohol gave large, golden prisms, m. p. 116—120° (Found: total OR, calculated as OMe, 18·1%). No definite conclusions as to the composition of these compounds could be based on these analyses, however, because the substance has combined with the alcohols, and the products are decomposed partially even by drying in a vacuum at the air temperature, as was done for the preparation of the analytical specimens; moreover, at 100° the crystals melt, then resolidify, and are converted gradually into 4-keto-1-methoxy-3-(3'-nitrophenyl)-3 : 4-dihydrophthalazine. The latter change was best effected by heating first at 100° and then at 140°, and, unlike the case of the 4'-nitro-isomeride, in this instance there was always simultaneous formation of a certain amount of a more complex substance, red needles, m. p. 289°, especially if heating was too rapid at first.

4-Keto-1-methoxy-3-(3'-nitrophenyl)-3 : 4-dihydrophthalazine crystallised from alcohol in long, colourless, prismatic needles, m. p. 182° (Found: C, 60·8; H, 3·9; N, 14·3; OMe, 10·2. $C_{15}H_{11}O_4N_3$ requires C, 60·6; H, 3·7; N, 14·1; OMe, 10·4%); it is readily soluble in chloroform, ethyl acetate, glacial acetic acid, and toluene,

and insoluble in dilute mineral acids or alkalis. When 1 g. was heated with glacial acetic acid and twice the volume of hydrobromic acid in a sealed tube at 100° for ½ hour, 1 : 4-*diketo*-3-(3′-*nitrophenyl*)-*tetrahydrophthalazine* separated on cooling, and after crystallisation from alcohol formed colourless needles, m. p. 280° (Found : C, 59·6; H, 3·3; N, 14·8. $C_{14}H_9O_4N_3$ requires C, 59·4; H, 3·2; N, 14·8%). It is insoluble in dilute mineral acids, but soluble in dilute sodium carbonate with a pale yellow colour.

3′-*Nitro*-3-*phenylphthalaz*-4-*one*.—Alcoholic solutions of *o*-phthalaldehydic acid and *m*-nitrophenylhydrazine were boiled under reflux as described for the 4′-nitro-isomeride (*loc. cit.*). After removal of about one-half of the alcohol, the *lactone* form of the phenylhydrazone separated in small, orange crystals, m. p. 240° after becoming colourless at 200° (Found : C, 58·7; H, 4·0; N, 14·6. $C_{14}H_{11}O_4N_3$ requires C, 58·9; H, 3·9; N, 14·7%). It is sparingly soluble in dilute hydrochloric acid and soluble in dilute sodium carbonate, but acidification of the alkaline solution gave 3′-nitro-3-phenylphthalaz-4-one and not the hydrazone, and the same substance was obtained in attempts to recrystallise the lactone form from alcohol or pyridine. The *phthalazone* was prepared most conveniently by boiling a nitrobenzene solution for a short time, and, after cooling, crystallised in colourless needles, m. p. 240° (Found : C, 62·8; H, 3·5; N, 16·0. $C_{14}H_9O_3N_3$ requires C, 62·9; H, 3·4; N, 15·7%). It is soluble in alcohol, insoluble in sodium carbonate or hydroxide, and very sparingly soluble in hydrochloric acid. It neither forms a picrate nor reacts with methyl sulphate.

3′-*Amino*-3-*phenylphthalaz*-4-*one*.—To a fine suspension of 3′-nitro-3-phenylphthalaz-4-one in boiling water, made alkaline with sodium hydroxide, hydrosulphite was added until a clear solution was obtained. After cooling, 3′-*amino*-3-*phenylphthalaz*-4-*one* separated, and on recrystallisation from water formed colourless needles, m. p. 156° (Found : C, 71·2; H, 4·8; N, 17·5. $C_{14}H_{11}ON_3$ requires C, 70·9; H, 4·6; N, 17·7%). It forms a hydrochloride, clusters of colourless needles, and can be diazotised.

We desire to thank Alliance Colour and Chemical Co., and British Dyestuffs Corporation for gifts of sodium β-naphthol-1-sulphonate.

CCCXXXIX.—*Investigations on the Dependence of Rotatory Power on Chemical Constitution. Part XXXII. The Resolution of Phenylbenzylcarbinol.*

By WILLIAM GERRARD and JOSEPH KENYON.

IN view of the marked alterations in rotatory power and rotatory dispersion which are effected when an aromatic nucleus is introduced into the molecule of an aliphatic secondary alcohol (compare *inter alia*, Part XXV, J., 1925, **127**, 1094), it seemed desirable to study the effect of the introduction of two aromatic nuclei into the molecule of an aliphatic secondary alcohol.

With this object in view, the optically active modifications of phenylbenzylcarbinol have been prepared and their optical properties examined. The noteworthy results of this investigation are as follows: The effect of temperature on the rotatory power of the alcohol is very marked (Table I), there being a ten-fold increase on cooling from 125° to 20°, and the specific rotatory power of this alcohol at 20° is the largest yet recorded for a secondary alcohol; at the same time the rotatory dispersion ratio $\alpha_{4358}/\alpha_{5461}$ changes from 2·57 at 125° to 1·79 at 20°. The effect of solvents on the rotatory power is also very pronounced (Table II), the value of $[\alpha]^{25°}_{5461}$ changing from −11·0° in pyridine solution to +64·1° in ethyl-alcoholic solution, whilst in benzene solution the rotatory dispersion is anomalous. When the values of the specific rotatory powers of the alcohol in the homogeneous state are plotted against the squares of the wave-lengths of light used, the resulting curve is non-linear.

The acetate of *l*-phenylbenzylcarbinol, which is dextrorotatory, increases in rotatory power with rise of temperature, the values being given in Table III.

Phenylbenzylcarbinol has already been obtained in an optically active condition by Levene (*J. Biol. Chem.*, 1925, **65**, 507) by the method herein described, but the rotatory power obtained ($[\alpha]^{20°}_{D}$ + 18·54°) indicates that the resolution was incomplete.

EXPERIMENTAL.

Phenylbenzylcarbinol was prepared by adding an ethereal solution of benzaldehyde (96 g.) to a vigorously stirred and ice-cold ethereal solution of benzyl magnesium chloride, prepared from 126 g. of benzyl chloride, and working up the product in the usual way. The crude carbinol (m. p. 61°) was purified by crystallisation from light petroleum containing 5% of benzene, being thus obtained as white needles, m. p. 67°, b. p. 177°/15 mm.; yield 154 g., 78%.

Phenylbenzylcarbinyl hydrogen phthalate, prepared by heating a mixture of the carbinol (120 g.) and phthalic anhydride (90 g., previously crystallised from dry chloroform to remove traces of phthalic acid) at 120° for 24 hours and working up the product in the usual manner, was obtained (192 g., 91%), after crystallisation from a mixture of ether and light petroleum, in small needles, m. p. 131° (Found, by titration with NaOH: *M*, 347. Calc.: *M*, 346).

d-*Phenylbenzylcarbinyl Hydrogen Phthalate*.—Quinine (110 g.) was dissolved in a hot solution of *dl*-phenylbenzylcarbinyl hydrogen phthalate (100 g.) in acetone (200 c.c.), and the resulting *d*A,*l*B salt, which separated on standing, was removed by filtration and recrystallised four times from 1½ times its weight of ethyl alcohol, the rotatory power of the *d*-phenylbenzylcarbinyl hydrogen phthalate obtained from it by decomposition having then become constant. The pure *quinine* salt forms soft, silky needles, m. p. 205° (decomp.), which are too insoluble in cold solvents to allow of its rotatory power being determined; it was dissolved in the minimum amount of hot alcohol and the solution poured into a slight excess of dilute hydrochloric acid; the precipitated *d*-hydrogen phthalic ester, after washing and drying, was crystallised from acetic acid (40 c.c. of 90%) and subsequently from ether–light petroleum, being obtained as fine needles, m. p. 131°; yield 31 g., a further 7 g. being obtained by working up the mother-liquors: $[\alpha]_D^{25°}$ +32·75°, $[\alpha]_{5461}^{25°}$ +38·75° ($c = 5·0$, in ethyl alcohol, 99%).

l-*Phenylbenzylcarbinyl Hydrogen Phthalate*.—The partially active *l*-hydrogen phthalic ester (50 g.; $[\alpha]_{5461}^{25°}$ −30·7° in alcohol), obtained by the decomposition of the more soluble fractions of the quinine salt, was dissolved in methyl alcohol (150 c.c.) and the hot solution mixed with cinchonine (42·5 g.). The *l*A,*d*B salt, which separated from the solution on standing, after four recrystallisations from methyl alcohol containing 10% of acetone reached constancy of m. p., 110°, and of rotatory power, $[\alpha]_{5461}^{25°}$ +82·3° ($c = 4·90$ in ethyl alcohol). The pure *cinchonine* salt was dissolved in hot alcohol and decomposition effected as described above. The recrystallised *l*-phenylbenzylcarbinyl hydrogen phthalate has m. p. 131° and $[\alpha]_{5461}^{25°}$ −38·80° ($c = 5·00$ in ethyl alcohol); yield 31 g.

d- *and* l-*Phenylbenzylcarbinols*.—The free carbinols were obtained by gently boiling for 15 minutes the respective hydrogen phthalic esters with a slight excess of dilute aqueous sodium hydroxide. The liberated alcohols were extracted with ether and subsequently crystallised from ether–light petroleum; they each have m. p. 67°. Their rotatory powers are given in Table I.

l-*Phenylbenzylcarbinyl acetate* (l-α*β-diphenylethyl acetate*), prepared

by the slow addition of acetyl chloride (3 g.) to a solution of *l*-phenylbenzylcarbinol (6 g.) in dry pyridine (15 c.c.), was obtained as a colourless oil (6·3 g.), b. p. 182°/15 mm. (Found, by hydrolysis with alcoholic potassium hydroxide: *M*, 241. $C_{16}H_{16}O_2$ requires *M*, 240); $[\alpha]^{17°}_{5461}$ + 28·00°.

17	47·12	28·00	24·52	23·51	17·69	1·682

The specific rotatory power of this ester determined at 17° was found to be unchanged after the above data had been obtained. A portion of the ester was hydrolysed and the resulting carbinol possessed a rotatory power identical with that of the carbinol from which the ester was prepared. It is thus evident that no racemisation had taken place during either the esterification or the subsequent heating of the ester.

Determination of Densities.—

d-Phenylbenzylcarbinol: $d^{t°}_4$ = 1·0358 at 70°, 1·0251 at 86°, 1·0210 at 92°, 1·0152 at 100°, 1·0095 at 110°, 1·0031 at 120°.

l-Phenylbenzylcarbinyl acetate: $d^{t°}_4$ = 1·0831 at 17°, 1·0723 at 30°, 1·0552 at 50°, 1·0380 at 70°, 1·0214 at 90°, 1·0041 at 110°, 0·9958 at 120°, 0·9870 at 130°.

The authors desire to express their thanks to the Government Grant Committee of the Royal Society for a grant which has helped to defray the cost of this investigation.

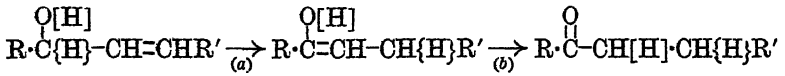
CCCXL.—*The Mobility of Symmetrical Triad (Prototropic*) Systems. Part III. Three-carbon Prototropy in an αγ-Diphenylallyl Ether.*

By CHARLES WILLIAM SHOPPEE.

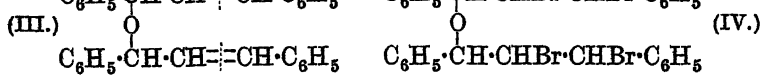


IN a recent communication (Burton and Ingold, this vol., p. 908, footnote), it was suggested that the transformation of α-arylated allyl alcohols to saturated ketones in the presence of alcoholic alkali

* This word has been added to the serial title to indicate the exclusion of triad *anionotropic* systems which are being concurrently investigated in these laboratories.

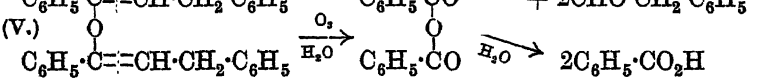
(Tiffeneau, *Bull. Soc. chim.*, 1907, **1**, 1209; Nomura, *ibid.*, 1925, **37**, 1245) occurred through the pinacolic electron displacement:

Alternatively, the change may be regarded as proceeding by three-carbon prototropy (*a*) succeeded by ketonisation (*b*):



In a paper (Ingold, Shoppee, and Thorpe, J., 1926, 1480) dealing with the mechanism of tautomerism in the so-called three-carbon system CH·C:C·C:O (which, according to the view there advanced, is not a symmetrical triad system but a pentad keto-enol complex; see also Ingold, *Ann. Report*, 1927, **24**, 114), it was shown that hydroxyl, and still better ethoxyl, ions should be extremely powerful catalysts for the $\alpha\beta$-$\beta\gamma$ change. When the theoretical reason for this is examined, it is seen to apply not only to this special case, but to the whole of prototropy, and thus, having regard to the experimental conditions of the reaction considered by Burton and Ingold, it seemed possible that the mobility of a truly triad three-carbon system was under observation. Since this condition has not previously been established, except for systems involved in a ring (*e.g.*, indene; Ingold and Piggott, J., 1923, **123**, 1469; compare Goss and Ingold, this vol., p. 1268), the mechanism of the reaction referred to appeared worthy of study.

An attempt is now described to differentiate between the mechanisms formulated above by investigating an ether of type (I). Here pinacolic electron displacement cannot occur, for there can be no ionisation of the alkyl group R, with consequent formation of an electron source to constitute the driving force of the rearrangement. On the other hand, three-carbon prototropy can take place with



(I.) R′·CH(OR)·CH:CHR″ R′·C(OR):CH·CH_2R″ (II.)

production of the isomeride (II), corresponding with process (*a*) above, but the substituent R will prevent further change [process (*b*) above]. Thus, if pinacolic electron displacement is the mechanism underlying the first-mentioned transformation, an ether of type (I) will be unaffected by treatment with alcoholic sodium ethoxide; but if the rearrangement can take place by a three-carbon prototropic change, equilibration of the ethers (I) and (II) is to be anticipated.

The ether examined was *bis-αγ-diphenylallyl ether* (III), an unsaturated crystalline solid which yields a *tetrabromide* (IV), and on fission with ozone gives benzaldehyde and benzoic acid.

This ether was heated with alcoholic sodium ethoxide, and the absence of an appreciable amount of phenyl β-phenylethyl ketone, which would be formed if hydrolysis of the ether linking occurred, was shown by treatment with semicarbazide. The product was a liquid isomeric with the ether (III); it was shown to consist essentially of the ether (V), since on fission with ozone it yielded the products, phenylacetaldehyde and benzoic acid, to be expected from a compound of this constitution.

Treatment with bromine confirmed this structure, four atoms being absorbed; the product, however, was not a saturated tetrabromide (VI) isomeric with (IV), but an unsaturated dibromide (VII), evidently formed from (VI) as a consequence of the well-known instability of halogens in α-halogeno-ethers ():

The position of equilibrium in hot alcoholic sodium ethoxide favours the isomeride (V) very largely, and it thus appears that the combined electronic affinities (inductive effect) represented in  C(H)·C:C are sufficient to produce (under the catalytic conditions mentioned) tautomeric mobility in a three-carbon system which is of a particularly simple type, since it is not implicated in a "developed" keto-enol complex.

Whether the reaction discussed by Burton and Ingold is to be represented by the first or the second of the mechanisms formulated at the outset cannot yet be decided, but the possibility of the second mechanism is clearly established by the example herein described.

EXPERIMENTAL.

Bis-αγ-diphenylallyl Ether (III).—αγ-Diphenylallyl alcohol was prepared from cinnamaldehyde and phenyl magnesium bromide and had m. p. 58° after crystallisation from ligroin (b. p. 40—60°).

The alcohol (15 g.), dissolved in glacial acetic acid, was treated with 75 g. of a 30% solution of hydrogen bromide in glacial acetic acid in the cold, and the mixture stirred for 2 hours. Pouring on ice, extraction with ether, washing (sodium hydrogen carbonate), drying, and evaporation of the ethereal extract yielded an oil which soon crystallised. After rubbing with a mixture of ether and ligroin, the *ether* was collected. It crystallised from ligroin (b. p. 60—80°), or from a large volume of methyl alcohol, in fine, rhombic prisms, m. p. 98—99° (Found: C, 89·5, 89·7; H, 6·6, 6·7. $C_{30}H_{26}O$ requires C, 89·5; H, 6·5%); yield, 13 g.

Bis-βγ-dibromo-αγ-diphenylpropyl Ether (IV).—The above ether (1·0 g.), dissolved in chloroform, was treated with a chloroform solution of bromine; absorption of 2 mols. took place readily, and removal of the solvent yielded a pale yellow oil (Found: C, 50·1; H, 3·9. $C_{30}H_{26}OBr_4$ requires C, 49·9; H, 3·6%).

Ozonolysis of the Ether (III).—A solution of the ether (2·0 g.) in glacial acetic acid was treated with ozonised oxygen, and after decomposition of the ozonides, the product was separated into neutral and acid fractions. The former had the characteristic odour of benzaldehyde, which was identified as the phenylhydrazone, m. p. 156°; the yield was small, but the acid fraction, which consisted entirely of benzoic acid, was correspondingly large.

Bis-αγ-diphenylpropenyl Ether (V).—The ether (III) (2·0 g.) was added to a solution of sodium (2·0 g.) in 99·5% ethyl alcohol (25 c.c.), and the mixture boiled under reflux for 2 hours on a sand-bath. The product was poured into much water and extracted with ether, and the dried extract evaporated. The yellow oil obtained (Found: C, 88·5; H, 6·5. $C_{30}H_{26}O$ requires C, 89·5; H, 6·5%) decomposed on distillation in a vacuum; it was treated with alcoholic semicarbazide acetate solution for a week, but no semicarbazone separated, and the oil was recovered by pouring the solution into water and extraction with ether.

Bis-β-bromo-αγ-diphenylpropenyl Ether (VII).—The crude ether (V) was treated with 2·5 mols. of bromine in chloroform solution. Addition took place at first, but hydrogen bromide was soon evolved. Hydrogen bromide and chloroform were removed by evaporation on the steam-bath; the oil obtained, which did not solidify when kept over potash in a vacuum, was dissolved in ether, and the solution filtered and evaporated. Analysis indicates that, although not quite pure, the product consists essentially of the dibromo-compound (VII) (Found: C, 62·0; H, 4·1. $C_{30}H_{24}OBr_2$ requires C, 64·3; H, 4·3%). It quickly decolorises an alkaline solution of permanganate in aqueous acetone.

Ozonolysis of the Ether (V).—The ether (2·0 g.), dissolved in glacial

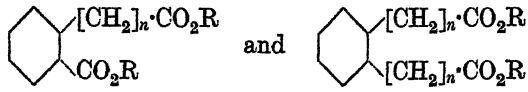
acetic acid, was treated with ozonised oxygen. After decomposition of the ozonides, the product was separated into neutral and acid fractions. The former on treatment with alcoholic semicarbazide acetate solution yielded a fluffy precipitate after several days (absence of benzaldehyde); this was filtered off, and after two crystallisations from methyl alcohol, separated in needles, m. p. 153°, identified as phenylacetaldehydesemicarbazone. The acid fraction was systematically crystallised from ligroin; benzoic acid was obtained, but no trace of phenylacetic acid could be detected.

Phenyl β-Phenylethyl Ketone Semicarbazone.—The ketone, m. p. 72—73°, prepared by the method of Perkin and Stenhouse (J., 1891, **59**, 1007), was treated with alcoholic semicarbazide acetate solution, and the *semicarbazone* crystallised out during 24 hours; it separated from dilute alcohol in needles, m. p. 144° (Found: C, 72·0; H, 6·4. $C_{16}H_{17}ON_3$ requires C, 71·9; H, 6·4%).

The author wishes to express his thanks to Professor C. K. Ingold, F.R.S., for his interest and advice, and to the Royal Commissioners of the 1851 Exhibition for a Senior Studentship.

THE UNIVERSITY, LEEDS. [*Received, August 16th*, 1928.]

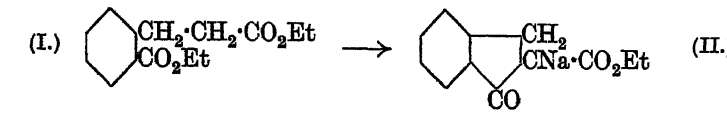
CCCXLI.—*Conditions of Formation of Rings attached to the* o-, m-, *and* p-*Positions of the Benzene Nucleus. Part III.*



By ALAN FRANCIS TITLEY.

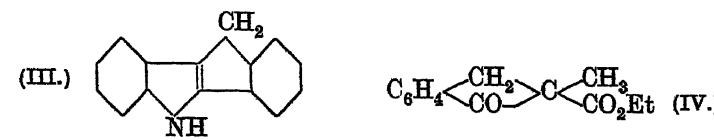
IN Part I of this series (J., 1922, **121**, 1562) the scope of the proposed investigation was defined as (i) the determination of the limit of size of rings which can be attached to the ortho-positions of the benzene nucleus, and (ii) an enquiry into the possibility of synthesising such rings in the meta- and para-series.

The synthesis of rings of this second type had been previously claimed by von Braun and his collaborators (*Ber.*, 1912, **45**, 1274; 1918, **51**, 1217, 1225; 1919, **52**, 2015; 1925, **58**, 281), and in one case (von Braun, Karpf, and Garn, *Ber.*, 1920, **53**, 98) a supposed heterocyclic "meta-ring" was converted into a homocyclic ring. It was shown, however, in Part II of this series (J., 1926, 508), that in this particular instance both the supposed heterocyclic and homocyclic "meta-rings" of von Braun were in reality benzene compounds containing simple side-chains in the meta-positions.



In the present communication some further results of the

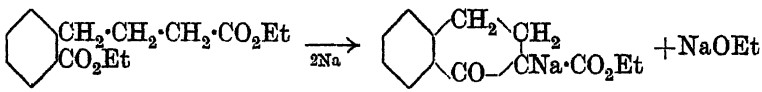
application of the Dieckmann reaction (the standard reaction chosen) to esters of the type



are described, together with some attempts to effect meta- and para-ring closure by the same methods.

Five-membered Ring.—The formation of a five-membered ring by the action of sodium on *o*-phenylenediacetic ester was described in Part I (*loc. cit.*). It is now found that condensation occurs, though less readily, when one of the reacting carbethoxy-groups is directly attached to the benzene nucleus. Thus, sodium reacts with a toluene solution of *ethyl* β-o-*carbethoxyphenylpropionate* (I) at 100°, forming ethyl sodio-1-hydrindone-2-carboxylate (II), about 20% of the ester (I) apparently being saponified. Acidification of the

sodium derivative yielded ethyl 1-hydrindone-2-carboxylate (compare Mitchell and Thorpe, J., 1910, **97**, 2273), which was hydrolysed almost quantitatively by acids or alkalis to 1-hydrindone (compare Part I, p. 1563). The phenylhydrazone of this ester, or a mixture of it with dry phenylhydrazine hydrochloride, was converted by concentrated hydrochloric acid into 2 : 3-*indeno*(1 : 2)-*indole* (III),

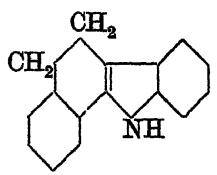


the *N*-methyl compound of which has been described by Armit and Robinson (J., 1922, **121**, 838).

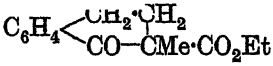
Ethyl 2-methyl-1-hydrindone-2-carboxylate (IV) was readily obtained by the action of methyl iodide on (II) (Mitchell and Thorpe, *loc. cit.*). The introduction of the methyl group into the 1-hydrindone ring appears to decrease the reactivity of the ketonic grouping, since, unlike the 1-methyl-2-hydrindone-1-carboxylic ester, the above ester does not readily form a phenylhydrazone or a semicarbazide. In both esters, however, the stability of the ring is decreased. Thus, on hydrolysis, (IV) yields, in addition to 2-methyl-1-hydrindone (Mitchell and Thorpe, *loc. cit.*), β-o-*carboxyphenyliso-butyric acid*. These results are of some importance in connexion

with those obtained in attempting to prepare meta- and para-ring structures.

Six-membered Ring.—The formation of ketotetrahydronaphthalenecarboxylic acids by the dehydration of various γ-phenylbutyric acids has been investigated by Attwood, Stevenson, and Thorpe (J., 1923, **123**, 1755), who have shown that β-substituted phenylbutyric acids, which contain in addition another carboxyl group, readily yield the six-membered ring under the action of sulphuric acid at room temperature. Unsubstituted phenylbutyric acid, however, according to Krollpfeiffer and Schäfer (*Ber.*, 1923, **56**, 620), is not dehydrated at room temperature and only to the extent of 50% at 100°.



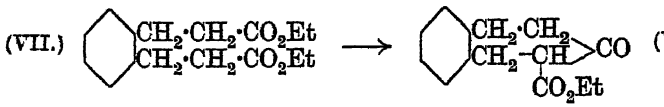
The " internal acetoacetic ester " condensation



gives a 70% yield in toluene at 100°, and therefore does not take place so readily as either of the two reactions previously described leading to the formation of five-membered rings.

Ethyl 1-keto-1 : 2 : 3 : 4-tetrahydronaphthalene-2-carboxylate (compare Hückel and Goth, *Ber.*, 1924, **57**, 1285) is almost quantitatively converted on hydrolysis with acids or alkalis into 1-keto-1 : 2 : 3 : 4-tetrahydronaphthalene (α-tetralon); it does not give a crystalline phenylhydrazone but, on treatment with phenylhydrazine hydrochloride and hydrochloric acid, it yielded 1 : 2-*indolo*(2 : 3)-3 : 4-*dihydronaphthalene* (V), and its sodio-derivative is methylated by methyl iodide to *ethyl* 1-*keto*-2-*methyl*-

(V.)



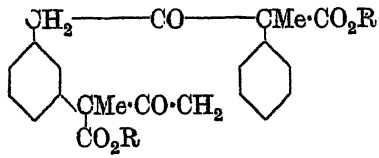
(VI.)

1 : 2 : 3 : 4-*tetrahydronaphthalene*-2-*carboxylate* (VI); by acid hydrolysis (VI) is quantitatively converted into 1-*keto*-2-*methyl*-1 : 2 : 3 : 4-*tetrahydronaphthalene*, whilst alkaline hydrolysis yields a mixture of this ketone with γ-*o*-*carboxyphenyl*-α-*methylbutyric acid*, again pointing to a destabilisation of the saturated ring on the addition of a methyl group.

Seven-membered Ring.—*o*-Phenylenedipropionic ester (VII) was found to be only slowly attacked by finely divided sodium in toluene at 100°, being almost entirely saponified; about 2—3%, however,

condensed to give (VIII), which was characterised by means of its *phenylhydrazone*. From these results the formation of a seven-

membered ring by the condensation of two three-membered side-chains in the ortho-position does not appear to be easily brought about. The formation of 1-ketophenheptamethylene from δ-phenylvaleryl chloride by the Friedel–Crafts reaction (Kipping and Hunter, J., 1903, **83**, 246) and the more recent work of von Braun and Bayer (*Ber.*, 1927, **60**, 1257) suggest, however, the probability that ring-closure by means of the Dieckmann reaction on *o*-carboxyphenylvaleric ester might be more readily effected.



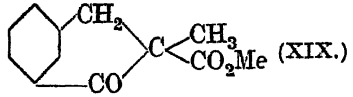
m- *and* p-*Ring-closure*.—From the theoretical standpoint there appears to be no valid reason why meta- and para-ring structures should not be capable of a stable existence, but the uncertainty of the benzene structure and the possibility that the rings would not be co-planar render it difficult to predict the most favourable conditions for their formation. The attempts described below to prepare such rings by the methods used for ortho-ring formation led to no conclusive result, but illustrate the difficulties of the problem. The action of sodium at 100° on toluene solutions of the following esters was investigated (R = Me or Et):

	meta-Series.	*para*-Series.
$C_6H_4<^{X—CO_2R}_{Y—CO_2R}$	(IX): X=C_2H_4; Y=C_2H_4.	(X): X=C_2H_4; Y=C_2H_4.
	(XI): X= —; Y=C_2H_4.	(XII): X= —; Y=C_2H_4.
	(XIII): X=CH_2; Y=CH_2.	(XIV): X=CH_2; Y=CH_2.
	(XV): X=CH_2; Y= —.	

Certain regularities of behaviour were observed. Thus (IX) and (X) (R = Et) and (XII) (R = Me) were only very slowly acted on by sodium with gradual formation of the sodium salt of the acid. There was no trace of ring-formation or condensation reactions. On the other hand, (XI) (R = Me), (XIII) and (XIV) (R = Me and Et), and (XV) (R = Me) reacted with sodium almost as readily as the corresponding ortho-esters under the same conditions, giving mixtures of sodium salts of the acids with unstable condensation products of varying degrees of molecular complexity, which could not be purified by distillation.

By employing the methyl esters, however, and methylating the resulting sodium compounds with methyl iodide, the products of the reaction could be separated by distillation under greatly reduced pressure. In addition to highly complex condensation products,

bimolecular compounds were isolated, presumably of "bridged-ring" structure of the type shown (from XIII).



Finally, in each case a lower-boiling product was obtained, consisting mainly of the dimethyl ester, regenerated by the action of the methyl iodide on the disodium salt of the acid which had been produced in the original reaction. The hydrolysis of these low-boiling fractions yielded, in the case of (XIII) and (XIV), not only the simple acids, but also small quantities of the α-methylated acids (XVI) and (XVII), respectively. From (XI), the α-methylated acid

(XVI.) m-C_6H_4<$^{CHMe\cdot CO_2H}_{CH_2\cdot CO_2H}$ p-C_6H_4<$^{CHMe\cdot CO_2H}_{CH_2\cdot CO_2H}$ (XVII.)

(XVIII) was similarly obtained, the position of the methyl group in this instance being settled by synthesising the acid for comparison. On the other hand, no α-methylated acid was obtained in this way from (XV).

These two facts appeared to render it doubtful whether the formation of these α-methylated acids could be safely attributed to direct methylation of an α-methylene group, in each open-chain ester, which had been rendered slightly "acid" in character by its position between the phenyl and carbethoxy-groupings. It appeared possible that traces of meta- and para-ring compounds, *e.g.*, of the type (XIX) from (XI), were actually present in the low-boiling fractions, which gave rise to the α-methylated acids, *e.g.*, (XVIII), on hydrolysis. The low-boiling fractions were carefully

(XVIII.) m-C_6H_4<$^{CH_2\cdot CHMe\cdot CO_2H}_{CO_2H}$

(XIX.)

examined for traces of ketonic substances, but none could be detected. The possibility is nevertheless not entirely excluded because, as previously mentioned, the keto-group in methylated hydrindonecarboxylic esters of the normal type is not very reactive.

The mechanism by which the esters appear to be directly converted in toluene solution into the sodium salts of the corresponding acids is somewhat obscure and is being further investigated.

EXPERIMENTAL.

β-o-*Carboxyphenylpropionic Acid.*—o-Aldehydobenzoic acid (25 g.) is condensed with malonic acid (45 g.) in glacial acetic acid (20 g.) in presence of anhydrous sodium acetate (15 g.). The

mixture is heated for 8—10 hours at 100°, cooled, and diluted with 150 c.c. of water, whereby monohydrated phthalideacetic acid, m. p. 102—104°, is precipitated in nearly quantitative yield. (Drying in a steam-oven gives the anhydrous acid, m. p. 151°; compare Edwards, J., 1926, 813.) This condensation may also be effected in dry pyridine solution containing a trace of piperidine, the yield being practically the same. The acid is boiled with an excess of 25% sodium hydroxide for about 2 hours, cooled in ice, and acidified with the theoretical quantity of dilute hydrochloric acid; *o*-carboxycinnamic acid then separates as a thick pasty mass, which is filtered and washed with a large volume first of cold and then of boiling water. The crude acid melts at 194°, and after recrystallisation from alcohol forms small prisms, m. p. 197° (Found: C, 62·5; H, 4·2. Calc. for $C_{10}H_8O_4$: C, 62·5; H, 4·2%). Ehrlich (*Monatsh.*, 1888, **9**, 528), Edwards (*loc. cit.*), and Gabriel give m. p. 184°, 182°, and 173—175° respectively, but the acid passes into phthalideacetic acid on melting, for on re-melting it has m. p. 151°.

The *o*-carboxycinnamic acid is reduced by means of sodium amalgam to *o*-carboxyphenylpropionic acid, m. p. after recrystallisation 167° (Bamberger, *Ber.*, 1890, **23**, 1562, gives m. p. 165°); esterification of the latter acid by saturation of its boiling solution in ethyl alcohol with dry hydrogen chloride gives the *ethyl* ester, b. p. 182—183°/14 mm. (Found: C, 67·0; H, 7·11. $C_{14}H_{18}O_4$ requires C, 67·2; H, 7·20%).

Ethyl 1-*Hydrindone*-2-*carboxylate*.—Metallic sodium (5 g.) is finely granulated by shaking under boiling toluene (100 g.), and a solution of *o*-carboxyphenylpropionic ester (24 g.) in toluene (50 g.) is added. The reaction proceeds smoothly at 100° and is complete in 4—5 hours; the resulting sodium compound (II) dissolves to a considerable extent in the toluene (compare Sidgwick and Brewer, J., 1925, **127**, 2381) and is precipitated on addition of dry ether. On decomposition with dilute acid, 1-hydrindone-2-carboxylic ester separates as an orange oil, b. p. 179—180°/15 mm. (slight decomp.) (Found: C, 70·8; H, 6·0. Calc.: C, 70·6; H, 5·9%) (Mitchell and Thorpe, *loc. cit.*, give b. p. 185°/20 mm.); the phenylhydrazone (Found: C, 73·5; H, 6·35; N, 9·5. Calc.: C, 73·5; H, 6·1; N, 9·5%) has m. p. 103° (Mitchell and Thorpe, *loc. cit.*, give m. p. 101·5°).

Hydrolysis. The ester (5 g.) was mixed with an aqueous solution of 2·5 g. of sodium hydroxide and kept at room temperature for 24 hours; α-hydrindone separated as an oil in almost quantitative yield; b. p. 164—166°/20 mm., m. p. 39°. The phenylhydrazone had m. p. 130° (compare Liebermann, *Ber.*, 1898, **31**, 2081).

2 : 3-*Indeno*(1 : 2)-*indole* (III).—1-Hydrindone-2-carboxylic ester (4 g.), mixed with dry phenylhydrazine hydrochloride (2·8 g.) and

two drops of concentrated hydrochloric acid, is heated first on the water-bath and afterwards at 150° for about 2 minutes; the solid brownish cake is broken up, washed with water, and extracted with hot methyl alcohol. On cooling, small brownish-red plates are deposited, m. p. 251° (Found: N, 6·6. $C_{15}H_{11}N$ requires N, 6·8%).

Ethyl 2-Methyl-1-hydrindone-2-carboxylate.—1-Hydrindone-2-carboxylic ester (10 g.) was converted into the sodium derivative by adding its ethereal solution to sodium previously granulated under toluene. The bright yellow, flocculent mass was collected, washed with a little dry ether, suspended in 100 c.c. of alcohol and boiled with 10 g. of methyl iodide for 3 hours. The ester which separated on addition of water boiled at 166°/14 mm. (Mitchell and Thorpe, *loc. cit.*, give b. p. 181°/20 mm.) and solidified in long prisms, m. p. 31° (Found: C, 71·5; H, 6·5. Calc. for $C_{13}H_{14}O_3$: C, 71·5; H, 6·4%). The ester, on boiling with 20% methyl-alcoholic potash, was hydrolysed to the extent of about 60% to 2-methyl-1-hydrindone, b. p. 125—126°/18 mm. (Found: C, 81·8; H, 6·8. Calc.: C, 82·2; H, 6·8%), and to the extent of about 40% to β-*o-carboxyphenyl*isobutyric *acid*, colourless needles, m. p. 141° (Found: C, 63·4; H, 5·8. $C_{11}H_{12}O_4$ requires C, 63·5; H, 5·8%).

Ethyl γ-o-Carbethoxyphenyl-n-butyrate.—The acid was obtained by the method of Hückel and Goth (*loc. cit.*), and its *ethyl* ester, prepared in the usual manner, had b. p. 188—189°/14 mm. (Found: C, 68·0; H, 7·7. $C_{15}H_{20}O_4$ requires C, 68·2; H, 7·6%).

Ethyl 1-Keto-1 : 2 : 3 : 4-tetrahydronaphthalene-2-carboxylate.—The preceding ester (19 g.) was slowly added to sodium (3·5 g.) dispersed in toluene (100 g.). The reaction was complete after 6—7 hours at 100°. After addition of a little alcohol to decompose traces of unchanged sodium, powdered ice was added, and the mixture made just acid by the addition of 15 c.c. of concentrated hydrochloric acid. The toluene layer was separated, washed with sodium carbonate solution, dried, and the solvent removed under diminished pressure; 10 g. of crude 1-ketotetrahydronaphthalene-2-carboxylic ester (65% yield) were obtained, b. p. 183°/15 mm., m. p. 33° (Hückel and Goth give m. p. 34°). From the aqueous layer and sodium carbonate washings 3—4 g. of *o*-carboxyphenylbutyric acid were obtained on evaporation.

When warmed to 150° with the calculated quantity of phenylhydrazine hydrochloride and a little concentrated hydrochloric acid, the foregoing ester yields 1 : 2-*indolo*(2 : 3)-3 : 4-*dihydronaphthalene* (V), dark reddish plates, m. p. 161° (Found: N, 6·3. $C_{16}H_{13}N$ requires N, 6·4%).

Ethyl 1-Keto-2-methyl-1 : 2 : 3 : 4-tetrahydronaphthalene-2-carboxylate (VI).—An alcoholic solution of 11 g. of the ketonic ester is

added to 1·2 g. of sodium, previously dissolved in 20 c.c. of ethyl alcohol. After the addition of 15 g. of methyl iodide, the mixture is boiled for 2—3 hours, evaporated to a small bulk, and poured into water. The *methyl* compound separates as a colourless oil with a terpene-like odour; b. p. 183—184°/18 mm. (Found: C, 72·0; H, 6·9. $C_{14}H_{16}O_3$ requires C, 72·4; H, 6·9%). On steam distillation with 20% sulphuric acid, this is converted into 1-*keto*-2-*methyltetrahydronaphthalene*, b. p. 143°/20 mm. (Found: C, 82·0; H, 7·6. $C_{11}H_{12}O$ requires C, 82·5; H, 7·5%), whereas alkaline hydrolysis with 10% methyl-alcoholic potash gives a mixture of the above ketone with *γ-o-carboxyphenyl-α-methylbutyric acid*, prisms, m. p. 173° (Found: C, 64·9; H, 6·6. $C_{12}H_{14}O_4$ requires C, 64·9; H, 6·3%). The decrease in stability of the saturated ring on the addition of the methyl group is very strikingly exemplified in this instance, since the unmethylated ester is hydrolysed to *o*-carboxyphenylbutyric acid only by sodium and boiling *cyclo*hexanol, and then to an extent of not more than 20%.

Ethyl o-Phenylenedipropionate (VII).—The acid was prepared by the method of Perkin (J., 1888, **53**, 18); after purification by means of the diethyl ester, it had m. p. 168° (Perkin found m. p. 160—162°, "not very sharply"). The *ethyl* ester had b. p. 200—202°/12 mm. (Found: C, 69·0; H, 7·8. $C_{16}H_{22}O_4$ requires C, 69·1; H, 7·9%).

Action of sodium on the ethyl ester. To sodium (1·8 g.), dispersed in toluene (60 g.), was added *o*-phenylenedipropionic ester (11·5 g.) dissolved in toluene (15 g.), and the mixture heated on the water-bath. After 9 hours, the toluene was filled with a deposit of brown sodium compounds and no unchanged metallic sodium could be detected. The sodium derivatives were filtered off rapidly, washed with dry ether, and decomposed with dilute hydrochloric acid. The brown, flocculent, oily material which separated was extracted with ether, and the ethereal solution thoroughly washed with sodium carbonate solution; on acidification of these sodium carbonate washings, a large quantity of a brownish powder was precipitated, which, after recrystallisation from dilute alcohol, formed microscopic prisms, m. p. 167—168°, and was found on analysis to be *o*-phenylenedipropionic acid; this acid (9 g.) constituted the main product of the reaction. From the ethereal solution was obtained about 0·5 g. of a brownish oil of b. p. approx. 190°/15 mm., which gave an immediate purple colour with ferric chloride. The amount was not sufficient for purification but, on warming with phenylhydrazine at 100° and then adding alcohol, a crystalline *phenylhydrazone* was obtained which formed straw-yellow needles, m. p. 198° (decomp.), from hot alcohol (Found: C, 74·6; H, 6·8; N, 8·55. $C_{20}H_{22}O_2N_2$ requires C, 74·5; H, 6·8; N, 8·7%).

This phenylhydrazone is thus almost certainly derived from *ethyl* 3-*ketophenheptamethylene*-2-*carboxylate* (VIII).

Action of Sodium on m- *and* p-*Phenylenediacetic Esters.*

These esters are conveniently obtained from the corresponding nitriles (see Part II, *loc. cit.*) by simultaneous hydrolysis and esterification by means of the appropriate alcohol saturated with dry hydrogen chloride. *Methyl* m-*phenylenediacetate* has b. p. 185—187°/15 mm. (Found: C, 64·9; H, 6·3. $C_{12}H_{14}O_4$ requires C, 64·8; H, 6·3%). *Ethyl* m-*phenylenediacetate* has b. p. 188—189°/12 mm. (Found: C, 66·8; H, 7·3. $C_{14}H_{18}O_4$ requires C, 67·2; H, 7·2%). *Methyl* p-*phenylenediacetate* has b. p. 189—190°/15 mm. (Found: C, 64·6; H, 6·2%). *Ethyl* p-*phenylenediacetate* has m. p. 59° (Found: C, 66·9; H, 7·1%).

Ethyl *m*-phenylenediacetate (48 g.) was slowly added to metallic sodium (10 g.) finely granulated under toluene (150 g.). On warming on the water-bath, a vigorous reaction set in which was complete in about 20 minutes. The mass of brown sodium compounds was filtered off quickly, washed with a large volume of dry ether, and dried in a vacuum. An iodoform test showed that considerable quantities of sodium ethoxide were present. The sodium compounds were decomposed with the theoretical quantity of ice-cold dilute hydrochloric acid and the viscous yellow product was extracted with ether. Free *m*-phenylenediacetic acid was removed by shaking with dilute sodium carbonate, and the ethereal solution dried and distilled. The syrup so obtained, on removal of the last traces of ether in a vacuum, set to a solid sticky mass, which softened and melted at 30—40° and decomposed vigorously above 100° (Found: C, 70·8; H, 6·3. $C_{12}H_{12}O_3$ requires C, 70·6; H, 5·9%). This *compound* showed no tendency to crystallise on standing for 9 months or on cooling to −40°, whilst attempts at distillation under pressures as low as 0·3 mm. led to complete decomposition, with formation of a horny, shellac-like mass. The alcoholic solution gave a deep purple colour with ferric chloride and a deep green copper salt with copper acetate, indicating the presence of a keto-enol structure, but no crystalline compound with phenylhydrazine could be isolated. Hydrolysis with alcoholic potash gave rise to yellowish, insoluble resins.

Almost precisely similar results were obtained with ethyl *p*-phenylenediacetate, but the syrupy product obtained combined fairly readily with phenylhydrazine, yielding an amorphous, red, glassy mass. This was extracted with boiling methyl alcohol, and the solution poured into a large volume of dry ether. A small quantity of microscopic yellow needles was obtained which softened at 190°

and melted at 194—195° (Found: C, 73·6; H, 6·3; N, 9·5. $C_{18}H_{18}O_2N_2$ requires C, 73·5; H, 6·1; N, 9·5%). As this *phenylhydrazone* was obtained in very small yield and its molecular weight was not determined, it cannot be regarded as positive evidence of the formation of a *p*-β-hydrindonecarboxylic ester.

The action of sodium on the two dimethyl esters was carried out in a similar manner. The sodium compounds were mixed with dry methyl alcohol and a slight excess of methyl iodide and boiled for 12 hours. The solution was then poured into water, and the methylated product extracted with ether, dried, and distilled under 1 mm. pressure. Starting with methyl *m*-phenylenediacetate, three main fractions were obtained: (*a*) b. p. 131—135°, (*b*) b. p. 217—222°, (*c*) 270° and upwards; (*c*) was not further investigated, as it appeared to be of a high degree of molecular complexity. The *compound* constituting the middle fraction (*b*) probably has the bridged-ring structure (p. 2575) (Found: C, 70·2; H, 6·3; *M*, cryoscopic in acetic acid, 418. $C_{24}H_{24}O_6$ requires C, 70·6; H, 5·9%; *M*, 408); on hydrolysis with 2—3% methyl-alcoholic potash it gives about a 40% yield of a colourless, amorphous powder, which is insoluble in sodium carbonate but dissolves in warm dilute sodium hydroxide. This *substance*, which appears to be a lactone or acid anhydride, sinters at 340° and melts fairly sharply at 345—346° (Found: C, 72·5; H, 5·1. $C_{22}H_{18}O_5$ requires C, 72·9; H, 5·0%).

The low-boiling fraction (*a*) redistilled at 182—190°/15 mm. and could not be further separated by fractionation. After hydrolysis with dilute methyl-alcoholic potash, the crude acid obtained was extracted with cold chloroform until the insoluble residue melted sharply at 169° (pure *m*-phenylenediacetic acid). The soluble portion was fractionally recrystallised from water to remove traces of the above acid from the more soluble *phenylene*-1-*acetic*-3-α-*propionic acid* (XVI), m. p. 132° (Found: C, 63·6; H, 6·0. $C_{11}H_{12}O_4$ requires C, 63·5; H, 5·8%).

The action of sodium on methyl *p*-phenylenediacetate gave similar results. The middle fraction had b. p. 225—228°/1 mm. (Found: C, 70·3; H, 6·2. $C_{24}H_{24}O_6$ requires C, 70·6; H, 5·9%). On hydrolysis, the low-boiling fraction (188—192°/16 mm.) gave a mixture of *p*-phenylenediacetic acid, m. p. 244°, and *phenylene*-1-*acetic*-4-α-*propionic acid* (XVII), m. p. 189° (Found: C, 63·3; H, 5·9. $C_{11}H_{12}O_4$ requires C, 63·5; H, 5·8%).

Action of Sodium on m- *and* p-*Carboxyphenylpropionic Esters.*

Preparation of Esters.—*m*-Carboxyphenylpropionic acid was prepared by condensing *iso*phthalaldehydic acid (Davies, Perkin,

and Clayton, J., 1922, **121**, 2215) with malonic acid in glacial acetic acid or pyridine to obtain *m*-carboxycinnamic acid, needles, m. p. 275° (corr.) (Simonis, *Ber.*, 1912, **45**, 1584, gives m. p. 264°) (Found: C, 62·5; H, 4·3. Calc.: C, 62·5; H, 4·2%), and reducing this with sodium amalgam and sodium carbonate solution to m-*carboxyphenylpropionic acid*, plates, m. p. 177° (Found: C, 61·6; H, 5·25. $C_{10}H_{10}O_4$ requires C, 61·8; H, 5·2%). The *methyl* ester, prepared from this in the usual way, had b. p. 184—185°/15 mm. (Found: C, 64·9; H, 6·5. $C_{12}H_{14}O_4$ requires C, 64·9; H, 6·3%).

p-Carboxyphenylpropionic acid was prepared by two methods. (1) *p*-Toluoyl chloride (1 mol.) treated at 185—190° with bromine (2 atoms) gave a mixture of ω-bromo-*p*-toluoyl chloride, b. p. 155—156°/20 mm., and *ω-bromo*-p-*toluoyl bromide*, b. p. 170—171°/20 mm., m. p. 56° (Found: Br, 57·8. $C_8H_6OBr_2$ requires Br, 57·5%), together with some high-boiling material which was not distilled but appeared to consist of a mixture of ωω-dibromo-*p*-toluoyl chloride and bromide, since, on mixing with alcohol it yielded *ethyl ωω-dibromo*-p-*toluate*, hexagonal prisms, m. p. 103° (Found: C, 36·8; H, 3·08. $C_{10}H_{10}O_2Br_2$ requires C, 37·2; H, 3·10%). *Ethyl ω-bromo*-p-*toluate*, prepared from the mixture of monobromo-acid chloride and bromide, has b. p. 165°/18 mm. and crystallises in needles, m. p. 35—36° (Found: Br, 32·7. $C_{10}H_{11}O_2Br$ requires Br, 32·9%); when condensed with chloromalonic ester, it gives a fair yield of *ethyl chloro*-p-*carbethoxybenzylmalonate*, b. p. 235°/20 mm., m. p. 54—55° (Found: Cl, 9·95. $C_{17}H_{21}O_6Cl$ requires Cl, 9·81%), which, on reduction with zinc dust and acetic acid, yields *ethyl* p-*carbethoxybenzylmalonate*, b. p. 218—219°/15 mm. (Found: C, 62·8; H, 6·6. $C_{17}H_{22}O_6$ requires C, 63·2; H, 6·8%). On hydrolysis this is converted into p-*carboxybenzylmalonic acid*, a microcrystalline powder, m. p. 186—188° (Found: C, 55·5; H, 4·6. $C_{11}H_{10}O_6$ requires C, 55·4; H, 4·3%). The dicarboxylic acid does not lose carbon dioxide readily, but on heating to 240° it is converted into *p*-carboxyphenylpropionic acid, m. p. 294° (Found: C, 62·0; H, 5·2. Calc.: C, 61·8; H, 5·2%). The yields in the last stages of this synthesis are not good.

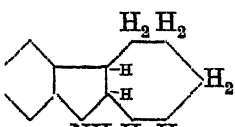
(2) The condensation of terephthalaldehydic acid with malonic acid gave a good yield of *p*-carboxycinnamic acid, a highly insoluble powder which, after subliming a little from 350° upwards, melts at 358° (decomp.) (Löw, *Annalen*, 1885, **231**, 367, gave no m. p.) (Found: C, 62·7; H, 4·3. Calc.: C, 62·5; H, 4·2%). The acid cannot be purified by recrystallisation, and this is best effected by converting it into the *ethyl* ester, which crystallises from dilute alcohol in prisms, m. p. 52° (Found: C, 67·5; H, 6·5. $C_{14}H_{18}O_4$ requires C, 67·8; H, 6·5%). On reduction of *p*-carboxycinnamic

acid with sodium amalgam and sodium carbonate, *p*-carboxyphenylpropionic acid, m. p. 294° (compare above) is obtained (Moses, *Ber.*, 1900, **33**, 2626, gave m. p. 280°). The *methyl* ester crystallises from chloroform in prisms, m. p. 33° (Found: C, 64·6; H, 6·47. $C_{12}H_{14}O_4$ requires C, 64·9; H, 6·3%).

Methyl *m*-carboxyphenylpropionate (27 g.), dissolved in toluene (20 g.), was added to sodium (5·6 g.) dispersed in toluene (60 g.), and the mixture heated for 12 hours on the water-bath. The sodium compounds were filtered off rapidly, washed with ether, suspended in 100 g. of dry methyl alcohol and, after the addition of 40 g. of methyl iodide, boiled for 3 hours. On distilling the product under 1 mm. pressure, two fractions were obtained at about 140°/1 mm. and 275°/1 mm. The low-boiling fraction redistilled at 183—187°/15 mm. and weighed 7·2 g. (Found: C, 66·0; H, 6·5%); 7 g. were hydrolysed in a sealed tube at 100° with 15 g. of 10% methyl-alcoholic potash, and on addition of water a clear brown solution was obtained, there being no evidence of ketone formation. The acidified solution was extracted with ether and yielded 6 g. of acid; two treatments of this crude product with 30 g. of cold chloroform extracted 1·55 g. and the residue then had m. p. 177°, thus being pure *m*-carboxyphenylpropionic acid. The chloroform-soluble acid was recrystallised several times from chloroform and finally from water to constant m. p. 137—138° (corr.) (Found: C, 63·6; H, 5·8. $C_{11}H_{12}O_4$ requires C, 63·5; H, 5·8%). It was proved to be β-m-*carboxyphenylisobutyric acid* (XVIII) by the following synthesis.

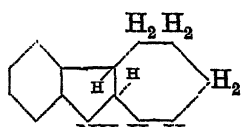
m-Toluoyl chloride was chlorinated at 160—165°, until the gain in weight was equivalent to one atom of chlorine. This gave a 90% yield of *ω-chloro-m-toluoyl chloride*, b. p. 149—150°/20 mm. (Found: Cl, 37·2. $C_8H_6OCl_2$ requires Cl, 37·6%), which on mixing with alcohol yielded *ethyl ω-chloro-m-toluate*, b. p. 168—169°/25 mm. (Found: C, 60·2; H, 5·7; Cl, 17·6. $C_{10}H_{11}O_2Cl$ requires C, 60·4; H, 5·5; Cl, 17·9%). This chloro-ester condensed with sodiomethylmalonic ester to give *ethyl m-carbethoxybenzylmethylmalonate*, which distilled without decomposition at 234°/24 mm. (Found: C, 63·8; H, 7·0. $C_{18}H_{24}O_6$ requires C, 64·3; H, 7·1%). The corresponding *acid*, obtained on hydrolysis, is a microcrystalline powder fairly soluble in water, m. p. 182—183° (decomp.). On heating to 185° until no more carbon dioxide is evolved, it is converted into β-*m*-carboxyphenyl*iso*butyric acid. The crude product had m. p. 136—137°, but after conversion to the *methyl* ester, b. p. 182°/18 mm., distilling, and re-hydrolysing, it crystallised from water in small prisms, m. p. 138—139° (Found: C, 63·7; H, 5·9%). The mixed m. p. of this acid with that obtained above was 138°.

m- *and* p-*Phenylenedipropionic Esters.*—The respective acids were obtained by the method of Kipping (J., 1888, **53**, 21). *Ethyl* m-*phenylenedipropionate* has b. p. 197—198°/15 mm. (Found: C, 68·8; H, 7·95. $C_{16}H_{22}O_4$ requires C, 69·1; H, 7·9%). *Ethyl* p-*phenylenedipropionate* crystallises in plates, m. p. 69° (Found: C, 68·9; H, 7·8%).



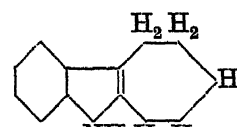
My thanks are due to the Ramsay Memorial Trustees for a Fellowship, during the tenure of which the greater part of this work was carried out, and to Professor W. H. Perkin for his advice.

THE DYSON PERRINS LABORATORY,
OXFORD. [*Received, April 4th,* 1928.]



CCCXLII.—*Stereoisomerism in Polycyclic Systems. Part V.*

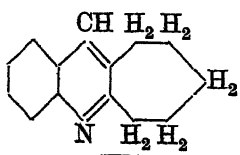
By WILLIAM HENRY PERKIN, jun., and SYDNEY GLENN PRESTON PLANT.



IT has been shown that although the reduction of tetrahydrocarbazole with tin and hydrochloric acid in aqueous alcohol leads almost entirely to the *cis*-modification of hexahydrocarbazole, the *trans*- being produced in only small amount (Gurney, Perkin, and Plant, J., 1927, 2676), yet the reduction of 2 : 3-dihydroquinindene under similar conditions gives relatively large quantities of both the *cis*- and the *trans*-form of 2 : 3 : 4 : 5 : 12 : 13-hexahydroquinindene (Perkin and Plant, this vol., p. 639). These facts were found to be in accordance with the deductions which could be drawn from a consideration of the relative strains in the various multiplanar configurations. The present communication deals with an extension of these considerations to some systems containing seven-membered rings. Owing to the fact that the multiplanar *cyclo*heptane ring can pass by free rotation into a strainless phase in which the *trans* valencies of two neighbouring carbon atoms, when projected on to a plane at right angles to the line joining these two atoms, enclose only a very small angle, it appears that there

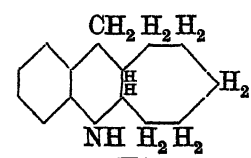
cis- (I.)

trans- (II.)



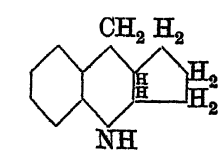
(III.)

should be relatively less strain in the *trans*-configuration of 2 : 3 : 4 : 5 : 11 : 12-*hexahydroheptindole* (II) than in *trans*-hexahydro-



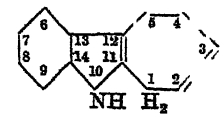
carbazole. It was thought, therefore, that the reduction of 2 : 3 : 4 : 5-*tetrahydroheptindole* * (III) with tin and hydrochloric acid in aqueous alcohol might lead to relatively large quantities of both the stereoisomeric hexahydro-derivatives (I) and (II).

2 : 3 : 4 : 5-Tetrahydroheptindole has been prepared by Fischer's indole synthesis from suberonephenylhydrazone, its reduction under the above conditions has been investigated, and the product has been found to consist almost entirely of a single form (presumably the *cis*-, since this is likely to be the less strained) of 2 : 3 : 4 : 5 : 11 : 12-hexahydroheptindole, not more than 5% of any stereoisomeride being present. This modification of hexahydroheptindole is basic, readily yielding a *picrate*, and *acetyl* and *benzoyl* derivatives. The isolation of the small quantity of the second form, which may possibly be present here as it was in the case of hexahydrocarbazole, was not attempted on account of the difficulty of obtaining the large amounts of suberone which would be required for such an investigation.

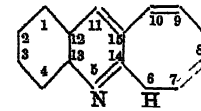


The results obtained in the above investigations suggested that a study of the reduction of 7 : 8 : 9 : 10-tetrahydroheptaquinoline † (IV) to 5 : 7 : 8 : 9 : 10 : 11 : 14 : 15-octahydroheptaquinoline (V) would be interesting. In this instance, as in the case of octahydroacridine (Perkin and Sedgwick, J., 1924, **125**, 2437) and of 2 : 3 : 4 : 5 : 12 : 13-hexahydroquinindene (VI) (Perkin and Plant, *loc. cit.*), there should be very little difference in the strains of the

(IV.)



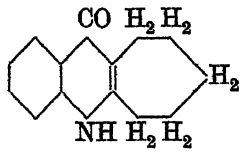
(V.)

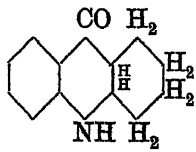


(VI.)

two stereoisomeric octahydro-derivatives, and relatively large quantities of the two forms should again be produced. We have pre-

* This substance is regarded as derived from the hypothetical parent compound " heptindole,"





† This substance is regarded as derived from the hypothetical parent compound " heptaquinoline,"

pared 7 : 8 : 9 : 10-tetrahydroheptaquinoline by the elimination of carbon dioxide from 7 : 8 : 9 : 10-tetrahydroheptaquinoline-11-carboxylic acid (compare Borsche, *Annalen*, 1910, **377**, 122), and have found that on reduction by means of tin and hydrochloric acid in aqueous-alcoholic solution it yields an oily base. By benzoylation (see Experimental), this was shown to consist almost entirely of one of the two possible forms of 5 : 7 : 8 : 9 : 10 : 11 : 14 : 15-*octahydroheptaquinoline*, admixed with a small amount of the unreduced tetrahydro-compound. The failure to isolate more than one stereoisomeride in these two reduced systems containing 7-membered rings is surprising and difficult to explain. Previous work in this field has indicated that the constitution of the product is influenced by the nature of the reducing agent used and depends also upon the nature of the starting material. It was hoped, therefore, that the second stereoisomeride of 5 : 7 : 8 : 9 : 10 : 11 : 14 : 15-octahydroheptaquinoline would result from the reduction of 11-*keto*-5 : 7 : 8 : 9 : 10 : 11-*hexahydroheptaquinoline* (VII) with sodium amalgam. We have prepared this keto-derivative by condensing anthranilic acid with suberone, but have found that reduction under these conditions and subsequent benzoylation of the oily product yields a single benzoyl derivative identical with that obtained by the previous method.

(VII.)

(VIII.)

In Part I of this series (J., 1924, **125**, 2437), the formation of the two stereoisomeric octahydroacridines (A, m. p. 82°, and B, m. p. 72°) by the reduction of tetrahydroacridine with tin and hydrochloric acid in aqueous alcohol is described. The more recent developments of this work have made it desirable to determine the relative amounts of the two modifications produced under these conditions, and we have now found that the ratio of octahydroacridine (A) to octahydroacridine (B) in the product is approximately 1 to 4. The reduction of tetrahydroacridone with sodium amalgam yielded entirely octahydroacridine (A) (Perkin and Sedgwick, *loc. cit.*), but it has been found during the course of the present work that the action of tin and hydrochloric acid on tetrahydroacridone in aqueous alcohol is to give a small quantity of a base which appears to be one of the two possible *hexahydroacridones* (VIII). This structure is confirmed by the fact that it gives an *oxime* (p. 2590).

EXPERIMENTAL.

2 : 3 : 4 : 5-*Tetrahydroheptindole.*—After equal weights of suberone and phenylhydrazine had been warmed together on the water-bath for 5 minutes and then cooled, the product solidified, and suberone-phenylhydrazone could be obtained from dilute alcohol in colourless needles, m. p. 72°. When a mixture of the crude hydrazone (18 g.), water (360 c.c.), and concentrated sulphuric acid (20 c.c.) was heated on the water-bath for 25 minutes with frequent shaking, 2 : 3 : 4 : 5-*tetrahydroheptindole* (11 g.) gradually separated in a practically pure condition. On crystallisation from alcohol it was isolated in colourless plates, m. p. 144° (Found: N, 7·4. $C_{13}H_{15}N$ requires N, 7·6%). The *picrate* was obtained from hot alcohol in dark crimson plates, m. p. 142°.

2 : 3 : 4 : 5 : 11 : 12-*Hexahydroheptindole.*—A mixture of 2 : 3 : 4 : 5-tetrahydroheptindole (10 g.), alcohol (30 c.c.), granulated tin (30 g.), and concentrated hydrochloric acid (30 c.c.) was boiled under reflux for 5 hours, filtered, the tin residues washed with a little hot alcohol, and the alcohol distilled off from the united filtrates. After being made alkaline with a concentrated aqueous solution of sodium hydroxide (30 g.) and cooled, the whole was filtered through asbestos, and both the solid and the filtrate were extracted with ether. The solid residue then remaining was dissolved in dilute hydrochloric acid, the solution was made alkaline with aqueous sodium hydroxide and again extracted with ether. When the united ethereal solutions were dried over potassium carbonate and the solvent removed, the residue solidified on cooling. On crystallising from alcohol, 2 : 3 : 4 : 5 : 11 : 12-*hexahydroheptindole* (2·9 g.) separated in colourless plates, m. p. 77°, unaltered by further recrystallisation (Found: C, 83·4; H, 9·2. $C_{13}H_{17}N$ requires C, 83·4; H, 9·1%). After removal of the solvent from the alcoholic filtrate, the residue melted at 67—70°, and crystallisation of this from a small quantity of alcohol yielded a further quantity (3·3 g.) of the hexahydroheptindole, m. p. 72—74° (mixed m. p. 73—75°). The solvent was then again removed from the filtrate, and the residue extracted with dilute hydrochloric acid, which left a small quantity of a dark red, resinous material. After the acid solution had been made alkaline with ammonia, the base obtained (2·0 g., m. p. 45—55°) was treated in hot alcohol with picric acid (2·5 g.). The picrate (2·4 g., equivalent to 1·1 g. of base) which separated, m. p. 176° (decomp.), proved to be identical with the picrate of 2 : 3 : 4 : 5 : 11 : 12-hexahydroheptindole described below, and, on decomposition with aqueous sodium hydroxide, it yielded the base, m. p. 77°. The alcoholic filtrate from the picrate was shaken with ether and dilute aqueous sodium

hydroxide, and the ethereal solution extracted with dilute hydrochloric acid. The small amount (0·6 g.) of base obtained by making this acid solution alkaline with ammonia melted at 35—45°, and on benzoylation gave a product which, after crystallisation from methyl alcohol, yielded 0·2 g. of the benzoyl derivative described below. It is thus apparent that not more than a very small quantity of any second stereoisomeride can be present in the product of the reduction of 2 : 3 : 4 : 5-tetrahydroheptindole by the above method.

2 : 3 : 4 : 5 : 11 : 12-Hexahydroheptindole forms a sparingly soluble *hydrochloride*, but this dissolves in much water, and the base is reprecipitated by adding ammonia. When the product obtained by boiling a solution of the base in acetic anhydride for 15 minutes, cooling and shaking with water, was crystallised from dilute alcohol, 10-*acetyl*-2 : 3 : 4 : 5 : 11 : 12-*hexahydroheptindole* was obtained in long, silky, colourless needles, m. p. 87° (Found : N, 6·3. $C_{15}H_{19}ON$ requires N, 6·1%). When the base was shaken with benzoyl chloride and aqueous sodium hydroxide, 10-*benzoyl*-2 : 3 : 4 : 5 : 11 : 12-*hexahydroheptindole* resulted; it separated from alcohol in clusters of colourless prisms, m. p. 116° (Found : N, 4·9. $C_{20}H_{21}ON$ requires N, 4·8%). The *picrate* of the base was isolated from alcohol in yellow prisms, m. p. 176° (decomp.).

7-*Bromo*-2 : 3 : 4 : 5-*tetrahydroheptindole*.—When suberone (4 g.) and *p*-bromophenylhydrazine (6 g.) were mixed in a small quantity of hot alcohol, *suberone*-p-*bromophenylhydrazone* separated, on cooling, in colourless plates, m. p. 57°, which quickly decomposed on exposure to the air. The alcoholic mixture was added to water (500 c.c.) containing concentrated sulphuric acid (60 c.c.), and the whole was boiled for 10 minutes. The product separated as a dark red oil, which solidified on cooling, and, after crystallisation from alcohol, 7-*bromo*-2 : 3 : 4 : 5-*tetrahydroheptindole* was obtained in colourless plates, m. p. 129—130° (Found : N, 5·5. $C_{13}H_{14}NBr$ requires N, 5·3%). It is not basic, being precipitated from its solution in concentrated sulphuric acid by pouring into water. The reduction of this substance by means of tin and hydrochloric acid in aqueous alcohol was studied, but partial debromination occurred during the process.

Reduction of 7 : 8 : 9 : 10-*Tetrahydroheptaquinoline*.—A mixture of 7 : 8 : 9 : 10-tetrahydroheptaquinoline (12 g., prepared from suberone and isatin as described by Borsche, *loc. cit.*), alcohol (60 c.c.), concentrated hydrochloric acid (60 c.c.), and granulated tin (60 g.) was boiled under reflux for 9 hours, a further quantity (20 c.c.) of hydrochloric acid being added after 5 hours. The liquid was then filtered, the solid residue washed with alcohol, and as much alcohol as possible removed by distillation from the united liquors. The

residue was made alkaline by the addition of a concentrated aqueous solution of sodium hydroxide (80 g.), and extracted several times with ether. After the extract had been dried over potassium carbonate and the solvent removed, the residual oil, which could not be made to solidify, was shaken with dilute aqueous sodium hydroxide and benzoyl chloride (15 g.). The solid product was dissolved in a considerable quantity of ether, the solution shaken with dilute hydrochloric acid, which removed a quantity (2·3 g., isolated by making the acid solution alkaline) of unreduced 7 : 8 : 9 : 10-tetrahydroheptaquinoline, dried over calcium chloride, and the solvent distilled off. The solid residue (13·3 g.) melted at 133—137°, and after crystallisation from alcohol, *5-benzoyl-5 : 7 : 8 : 9 : 10 : 11 : 14 : 15-octahydroheptaquinoline* (9·3 g.) separated in colourless prisms, m. p. 145° (Found: C, 82·8; H, 7·6. $C_{21}H_{23}ON$ requires C, 82·6; H, 7·5%). By concentrating the alcoholic mother-liquor, a further quantity (1·1 g.) of the benzoyl compound was obtained, and it is clear that no appreciable quantity of a stereoisomeride of this benzoyl compound can be present.

5 : 7 : 8 : 9 : 10 : 11 : 14 : 15-*Octahydroheptaquinoline*.—A solution of the benzoyl derivative (m. p. 145°) in aqueous-alcoholic potassium hydroxide was boiled for 24 hours, the alcohol removed, and the residue shaken with ether and water. The base was removed from the unchanged benzoyl compound, which was also present in the ether, by extraction with dilute hydrochloric acid, recovered by adding ammonia, and taken up in ether. 5 : 7 : 8 : 9 : 10 : 11 : 14 : 15-*Octahydroheptaquinoline* was collected as a colourless oil, b. p. 203°/24 mm. (Found: C, 83·9; H, 9·2. $C_{14}H_{19}N$ requires C, 83·6; H, 9·4%). Its *picrate* separated from alcohol in orange-red prisms, m. p. 196°.

11-*Keto*-5 : 7 : 8 : 9 : 10 : 11-*hexahydroheptaquinoline*.—This substance was obtained by a process analogous to that used by Tiedtke (*Ber.*, 1909, **42**, 624) for the preparation of tetrahydroacridone. Anthranilic acid (3·5 g.) and suberone (4 c.c.) were heated together at 120° for an hour and then at 210° for 15 minutes. The solid was boiled for 1½ hours with benzene, in which it is sparingly soluble, collected, and crystallised from alcohol; 11-*keto*-5 : 7 : 8 : 9 : 10 : 11-*hexahydroheptaquinoline* then separated in colourless plates, m. p. 344—345° (Found: N, 6·5. $C_{14}H_{15}ON$ requires N, 6·6%).

The keto-compound (6 g.), dissolved in boiling alcohol (300 c.c.) to which a little sodium bicarbonate had been added, was treated gradually at 80° with sodium amalgam (450 g. of 4%), the whole being vigorously stirred and carbon dioxide being passed continuously. After 6 hours, the mixture was filtered, the solid washed with alcohol, and the alcohol removed from the united filtrates

under reduced pressure. The residue was shaken with ether and water, the ether layer dried over potassium carbonate, and the solvent removed. After distilling under reduced pressure, the residual oil did not solidify, and, on shaking with benzoyl chloride (4·5 g.) and dilute aqueous sodium hydroxide, it yielded 5-benzoyl-5*:7:8:9:10:11:14:15-octahydroheptaquinoline, isolated from alcohol in colourless prisms, m. p. 145°. The mixture with the benzoyl compound obtained from the reduction product of 7:8:9:10-tetrahydroheptaquinoline also melted at 145°.

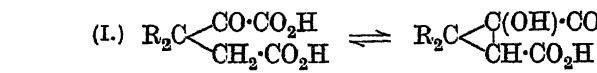
Reduction of Tetrahydroacridine with Tin and Aqueous-alcoholic Hydrochloric Acid.—A mixture of tetrahydroacridine (27 g.), alcohol (100 c.c.), concentrated hydrochloric acid (100 c.c.), and granulated tin (100 g.) was boiled under reflux for 5 hours, filtered, and the alcohol distilled off from the filtrate. The residue, after being made alkaline with sodium hydroxide (100 g. in concentrated aqueous solution), was extracted repeatedly with ether; from the extract, dried over potassium carbonate, a product was obtained which solidified on cooling and was crystallised from petroleum (b. p. 40—60°). Octahydroacridine (B) (6·7 g.) separated, and a further quantity (3·0 g.) was obtained by concentrating the mother-liquor. The petroleum was then completely removed, the residue heated to boiling for ½ hour with an excess of acetic anhydride, and the whole shaken with water (1500 c.c.) and left for several hours. The solid product was extracted with ether, and from the aqueous layer a small quantity (1·3 g.) of unchanged tetrahydroacridine was obtained by making it alkaline with ammonia and extracting it with ether. The extract containing the acetyl derivatives was shaken with dilute aqueous sodium carbonate, dried over calcium chloride, the solvent removed, and the residue crystallised from alcohol, 10-acetyloctahydroacridine (B) (7·0 g., m. p. 135—136°) being thus obtained; by distilling off the alcohol from the mother-liquor and crystallising the product from petroleum (b. p. 60—80°), a further quantity (1·7 g.) of the same substance was collected. After the mother-liquor was again evaporated to dryness, the residue was treated with potassium hydroxide (25 g.) in aqueous alcohol, and the whole boiled for 24 hours. The mixture, after removal of the alcohol, was diluted with water and shaken with ether; the ethereal layer was extracted with dilute hydrochloric acid and then evaporated, and the fact that no appreciable residue remained indicated complete hydrolysis of the acetyl derivatives. The aqueous acid solution was made alkaline with ammonia, and the basic product taken up in ether and dried with potassium carbonate. After removal of the ether, the residue (7·2 g.) solidified. It was dissolved in alcohol and treated with an alcoholic solution of picric acid (10 g.), whereupon the picrate of

octahydroacridine (A) (10·5 g., m. p. 198°) rapidly separated: the free (A) base was obtained from this by treatment with dilute aqueous sodium hydroxide and extraction with ether. The product remaining in the mother-liquor after removal of the picrate was clearly small and was essentially the picrate of octahydroacridine (B), for when the liquid was shaken with aqueous sodium hydroxide and ether, and the extracted base was crystallised from petroleum, octahydroacridine (B) (0·5 g., m. p. 72°) separated. The identities of the substances isolated were definitely established by mixed m. p. determinations with the products obtained as described by Perkin and Sedgwick (*loc. cit.*); the total amounts correspond to 17·3 g. of octahydroacridine (B) and 4·7 g. of octahydroacridine (A).

Hexahydroacridone.—A mixture of tetrahydroacridone (12 g.), alcohol (70 c.c.), concentrated hydrochloric acid (70 c.c.), and granulated tin (70 g.) was boiled for 6 hours, filtered, the alcohol removed, and the residue made alkaline with sodium hydroxide (70 g. in concentrated aqueous solution). After extraction with ether, drying with potassium carbonate, and removal of the solvent, the small quantity (about 0·5 g.) of solid obtained was crystallised from alcohol, from which *hexahydroacridone* separated in yellow plates, m. p. 180° (Found: C, 77·4; H, 7·7. $C_{13}H_{15}ON$ requires C, 77·6; H, 7·5%). The unreduced tetrahydroacridone was recovered by acidifying the mixture after the ether extraction with concentrated hydrochloric acid, collecting the hydrochloride, dissolving this in much water, and adding concentrated nitric acid. The nitrate of tetrahydroacridone gradually separated in a pure condition, and the free base was obtained from this with sodium hydroxide.

Hexahydroacridone, which is readily soluble in dilute hydrochloric acid, was treated in alcoholic solution with hydroxylamine hydrochloride and sodium acetate, the mixture boiled for 2 hours, the alcohol distilled off, and the residue shaken with water. The *oxime* separated from alcohol in pale yellow prisms, m. p. 215—216° (Found: N, 13·1. $C_{13}H_{16}ON_2$ requires N, 13·0%).

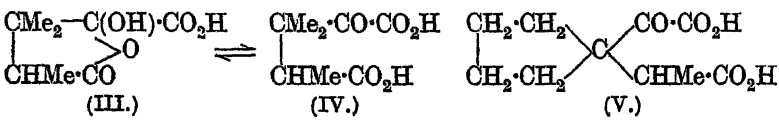
The authors wish to express their gratitude to Professor J. F. Thorpe for his gift of the suberone used in this work, and one of them (S. G. P. P.) wishes gratefully to acknowledge the receipt of a grant from the Chemical Society Research Fund, which has defrayed a part of the cost of this investigation.



THE DYSON PERRINS LABORATORY,
OXFORD.

[*Received, July 14th,* 1928.]

CCCXLIII.—*Experiments on the Synthesis of Certain γ-Ketonic Acids Closely Allied to Balbiano's Acid. Part I. Synthesis of α-Methylcyclopentane-1 : 1-diacetic Acid, of the Lactone of α-Hydroxy-α-methylcyclopentane-1 : 1-diacetic Acid, and of 1-Acetylcyclopentane-1-acetic Acid.*

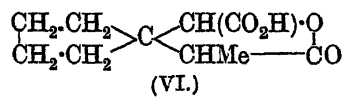


By JOGENDRA CHANDRA BARDHAN.

THE outcome of work which has been carried out in these laboratories during the past few years has been to show that in certain ββ-disubstituted ketoglutaric acids there exists a kind of tautomerism (keto-cyclol type) between the open-chain keto-form (I) and the hydroxy-ring form (II) (compare, *e.g.*, Deshapande and Thorpe, J., 1922, **121**, 1430; Bains and Thorpe, J., 1923, **123**, 1206). In

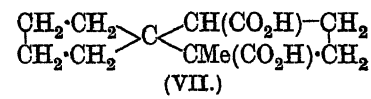
(I.) (II.)

the case of the corresponding acids containing an additional α-substituent, however, other factors come into play which considerably reduce the tendency to *cyclo*propane ring formation. The determining conditions are well illustrated in the case of an acid $C_8H_{12}O_5$ (Balbiano's acid), which has recently been dealt with by Kon, Stevenson, and Thorpe (J., 1922, **121**, 650), by Pandya and Thorpe (J., 1923, **123**, 2825), and by Rothstein, Stevenson, and Thorpe (J., 1925, **127**, 1072). Here, the usual keto-cyclol change is completely suspended, the substance exhibiting a marked tendency to pass into the lactol-form (III), which in the liquid state or in solution comes into equilibrium with the tautomeric parent (IV).



(III.) (IV.) (V.)

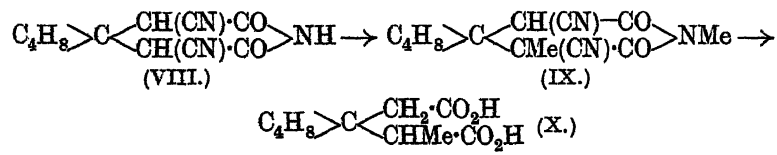
In view of the light which this phenomenon throws on the difficult question of the constitution of Balbiano's acid, it seemed desirable to ascertain the rôle played by the α-substituent, and, incidentally, to synthesise other keto-acids capable of exhibiting this kind of tautomerism.



In the course of an extended series of investigations on *spiro*- and associated alicyclic compounds, Thorpe and his co-workers have shown that the angle of the *cyclo*pentane ring is very close to that included between the *gem*-dimethyl groupings (Becker and Thorpe, J., 1920, **117**, 1579; Dickens, Kon, and Thorpe, J., 1922,

121, 1496; Lanfear and Thorpe, J., 1923, **123**, 1683; Ingold, Lanfear, and Thorpe, *ibid.*, p. 3140). It is to be expected, therefore, that the acid (V) would, if it could be synthesised, simulate the characteristic properties of Balbiano's acid. A general method of synthesis of α-ketoglutaric acids, indicated many years ago by Perkin and Thorpe (J., 1901, **79**, 737), consists in converting a substituted glutaric acid by means of the Hell–Volhard method into the dibromo-ester, from which the keto-acid is obtained either directly through the action of alkali or by further hydrolysis of the intermediate *cyclo*propane compounds through the agency of concentrated hydrobromic acid. Unfortunately, the above reaction breaks down in the case of the corresponding glutaric acids containing an additional α-substituent, owing to the occurrence of an abnormal decomposition, whereby the dibromo-ester is transformed into oxalic acid and an acid of the acrylic series (compare Pandya and Thorpe, *loc. cit.*, p. 2855; also Kon, Smith, and Thorpe, J., 1925, **127**, 567).

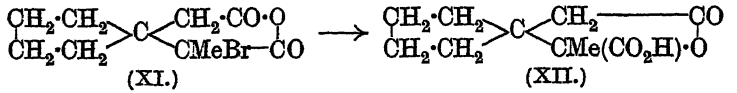
The necessity therefore arose of devising methods for the synthesis of αββ-trisubstituted ketoglutaric acids. A consideration of the conditions under which Balbiano's acid is produced showed that the synthesis of the *cyclo*pentane acid (V) might be attained through the oxidation of (i) the lactonic acid (VI) and (ii) the *spiro*-compound (VII) by means of alkaline permanganate, and a number of experi-



(VI.)

(VII.)

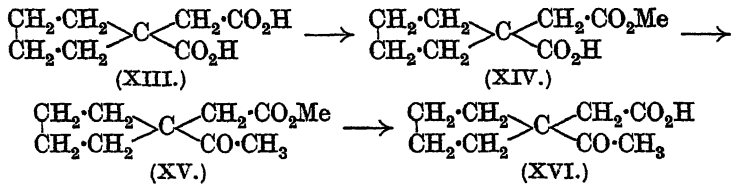
ments were made with this end in view. Although these attempts were unsuccessful, the results obtained led to the isolation of a number of substances of considerable interest.



The starting point in these attempts was *α-methylcyclopentane-1 : 1-diacetic acid* (X), which was prepared in quantity by methylating the imide (VIII) and hydrolysing the resulting *methylimide* (IX) with mineral acid. The *anhydride* of the acid (X) on treatment

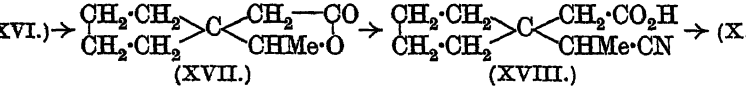
(VIII.) (IX.) (X.)

with the calculated amount of bromine gave a monobromo-compound (XI), which on hydrolysis with alkali readily furnished a crystalline lactonic *acid* (XII). This acid is very resistant to oxidising and reducing agents, and in this respect resembles the corresponding



gem-dimethyl lactonic acid prepared by Blanc (*Bull. Soc. chim.*, 1901, **25**, 68).

(XI.) (XII.)

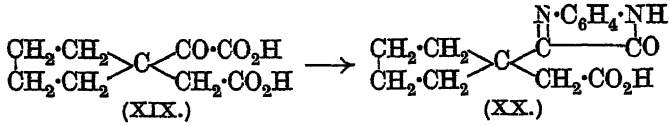


That the above scheme correctly represents the course of the bromination follows from the following synthesis of the lactonic acid (XII), which leaves no room for doubt as to its constitution.

1-*Acetyl*cyclo*pentane*-1-*acetic acid* (XVI) was first prepared in the following manner: *cyclo*Pentane-1-acetic-1-carboxylic acid (XIII), prepared by an extension of Lapworth and McRae's method (J., 1922, **121**, 2754), was successively converted into its *anhydride* and acid *ester* (XIV); the *acid chloride* of this ester was then allowed to react with zinc methyl iodide to give a product (XV), which on hydrolysis yielded 1-acetyl*cyclo*pentane-1-acetic acid.

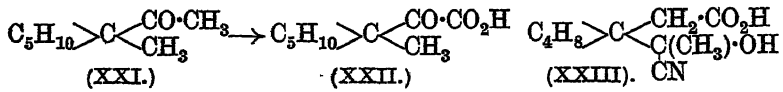
(XIII.) (XIV.) (XV.) (XVI.)

This synthesis, although simple and convenient as a method of preparation, does not provide an adequate basis for the constitution assigned to the acid (XVI), since the acid ester (XIV) might have an alternative structure. To settle this point, the keto-acid (XVI) was reduced with sodium and alcohol, the lactone (XVII) was converted by potassium cyanide into the cyano-compound (XVIII), and hydrolysis then yielded the acid (X), the identity of which was established by direct comparison.



(XVII.) (XVIII.)

1-Acetyl*cyclo*pentane-1-acetic acid shows all the properties of a ketonic acid; its *methyl* ester readily yields a *semicarbazone* and in this respect differs from its *cyclo*hexane analogue (Rothstein and Thorpe, J., 1926, 2014).



On oxidation with alkaline permanganate at the ordinary temperature the ketonic ester (XV) yielded an acid (XIX) which gave a condensation product (XX) with *o*-phenylenediamine. Although no authentic material was available for comparison, there can be no doubt that the acid is α-keto*cyclo*pentane-1 : 1-diacetic acid, previously obtained by Lanfear and Thorpe (J., 1923, **123**, 1688)

by the hydrolysis of the dibromo-ester of *cyclo*pentane-1 : 1-diacetic acid. Its formation in the present instance must have been due to

(XIX.) (XX.)

the oxidation of the methyl group, the reaction being precisely similar to the oxidation of the *cyclo*hexane ketone (XXI), which gives the keto-acid (XXII) as the sole product (Tarbourisch, *Compt. rend.*, 1910, **150**, 1606).

(XXI.) (XXII.) (XXIII).

The above reaction is very important, as it opens up a possibility of synthesising α-ketoglutaric acids, the preparation of which by the more obvious synthetical methods is either difficult or impossible. There can be no doubt, moreover, that the formation of trimethylpyruvic acid from pinacolin (Glucksmann, *Monatsh.*, 1889, **10**, 771) and of benzoylformic acid from acetophenone (Claus and Neukranz, *J. pr. Chem.*, 1891, **44**, 777) are instances of a very general reaction whereby an acetyl group attached to a quaternary carbon atom is similarly transformed into the corresponding oxalyl derivative.

In order to obtain the lactonic acid (XII), 1-acetyl*cyclo*pentane-1-acetic acid (XVI) was allowed to react with hydrocyanic acid, and under the prescribed conditions (p. 2602) combination readily took place with the formation of (XXIII), which on hydrolysis smoothly passed into the desired lactonic acid, which proved to be identical in all essential respects with that obtained in the bromination of α-methyl*cyclo*pentane-1 : 1-diacetic acid.

It therefore follows that in the bromination of the acid (X), the bromine atom has entered the carbon atom adjacent to the methyl group. It is somewhat remarkable that no trace of the isomeric bromo-derivative could be obtained, although Pandya and Thorpe (*loc. cit.*) succeeded in isolating both the possible lactonic acids from the products of the bromination of αββ-trimethylglutaric acid. On the other hand, Hariharan, Menon, and Simonsen (this vol., p. 432) obtained only one lactonic acid from the action of alkali on the monobromo-derivative of α-*iso*propylglutaric acid.

In order to avoid the formation of the lactonic acid (XII), it was next decided to brominate the monoethyl ester (prepared by partial hydrolysis of the normal ester) of α-methyl*cyclo*pentane-1 : 1-diacetic acid (XXIV), for in this case only the bromo-ester (XXV) could be formed, and on hydrolysis this should yield the desired

lactonic acid (VI). The bromination did not proceed very smoothly, however, and the crude product on treatment with alkali yielded a

$$C_4H_8\!>\!C\!<\!\begin{matrix}CH_2\cdot CO_2H\\CHMe\cdot CO_2Et\end{matrix} \longrightarrow C_4H_8\!>\!C\!<\!\begin{matrix}CHBr\cdot CO_2Et\\CHMe\cdot CO_2Et\end{matrix}$$

(XXIV.) (XXV.)

gummy acid from which no material of any definite composition could be obtained. On one occasion the impure acid was oxidised with alkaline permanganate and the resulting product was treated with *o*-phenylenediamine, but no trace of any quinoxaline derivative indicating the formation of the keto-acid (V) could be detected.

Finally, an attempt was made to prepare the lactonic acid (VI) by the hydrolysis of the *bromo*-compound (XXVI), which was readily prepared by direct bromination of the imide (IX); but on hydrolysis with concentrated hydrochloric acid the substance apparently lost bromine, the only isolable product being the acid (X), evidently derived from the original imide.

(XXVI.) $\begin{matrix}CH_2\cdot CH_2\\CH_2\cdot CH_2\end{matrix}\!>\!C\!<\!\begin{matrix}CBr(CN)-CO\\CMe(CN)\cdot CO\end{matrix}\!>\!NMe$

Several preliminary experiments have also been made with a view to synthesise the *cyclo*pentane analogue of camphoric acid (VII) by an extension of Komppa's method (*Annalen*, 1909, **370**, 209; **368**, 126), but these, together with a much easier method of preparing α-ketoglutaric acids which has now been discovered, are reserved for future communications.

During preliminary attempts to obtain the acid (X), a *ketone* was prepared from the acid (XXVII) (Wallach and Martins, *Annalen*, 1909, **365**, 272) by means of the Blaise reaction, and might therefore be expected to possess the αβ-structure (XXVIII). It readily yielded a mixture of two *semicarbazones*, one melting at 189° and the other at 169°; the regenerated ketones showed identical physical properties, and an exaltation characteristic of αβ-unsaturated ketones. Moreover, the corresponding *βγ-ketone* (XXX),

$$\begin{matrix}CH_2\cdot CH_2\\CH_2\cdot CH_2\end{matrix}\!>\!C\cdot CMe\cdot CO_2H \longrightarrow \begin{matrix}CH_2\cdot CH_2\\CH_2\cdot CH_2\end{matrix}\!>\!C\cdot CMe\cdot COMe$$

(XXVII.) (XXVIII.)

$$\begin{matrix}CH_2\cdot CH_2\\CH_2-CH\end{matrix}\!>\!C\cdot CHMe\cdot CO_2H \longrightarrow \begin{matrix}CH_2\cdot CH_2\\CH_2-CH\end{matrix}\!>\!C\cdot CHMe\cdot COMe$$

(XXIX.) (XXX.)

prepared from the acid (XXIX) (Wallach and Martins, *loc. cit.*, p. 271), gave a *semicarbazone* melting at 144°, and was markedly different from the αβ-ketones in physical properties. It seems probable that the semicarbazones are stereoisomeric like those of mesityl oxide (Wilson and Heilbron, J., 1913, **103**, 378). It is

proposed to investigate the action of ultra-violet light on these semicarbazones with a view to determine whether and under what conditions they may be interconvertible.

EXPERIMENTAL.

A. *Synthesis of α-Methyl*cyclo*pentane*-1 : 1-*diacetic Acid* (X).

The imide of αα′-dicyano*cyclo*pentane-1 : 1-diacetic acid was prepared by condensing *cyclo*pentanone with cyanoacetic ester and alcoholic ammonia (Kon, J., 1921, **119**, 818; Kon and Thorpe, J., 1919, **115**, 686). The crude product (yield 60%), after having been dried in the steam-oven, was directly used in the experiments described below.

N-*Methyl-ω-imide of αα′-Dicyano-α-methyl*cyclo*pentane*-1 : 1-*diacetic Acid* (IX).—In the preparation of this substance by an extension of Kon and Thorpe's method (J., 1922, **121**, 1795), it was found essential to adhere to the following conditions: The above imide (108 g.), dissolved in absolute alcohol (300 c.c.), was gradually added with vigorous shaking to a solution of sodium ethoxide prepared from sodium (35 g.) and absolute alcohol (500 c.c.); the biscuit-coloured sodium salt which separated was cooled in ice, cautiously mixed with methyl iodide (100 c.c.), and the mixture allowed slowly to attain room temperature. After 12 hours, the clear solution was heated under reflux on the steam-bath until neutral. The greater part of the alcohol was then evaporated off, the residue mixed with water (2 l.), and slightly acidified with hydrochloric acid. The methylated imide which separated as a viscous gum was washed with hot water, and when left in contact with methylated spirit gradually solidified to a brittle resin. This was thoroughly ground in a mortar with alcohol and the solid collected, washed successively with sodium sulphite solution, water, and alcohol, and dried. The material (90 g.), m. p. 132—135°, is sufficiently pure for most purposes, but can be recrystallised from alcohol, from which it separates as minute, colourless prisms, m. p. 136—137° (Found: C, 63·6; H, 6·2; N, 17·4. $C_{13}H_{15}O_2N_3$ requires C, 63·7; H, 6·1; N, 17·1%). The *imide* slowly dissolves in alkali and is reprecipitated on the addition of dilute acids.

*Hydrolysis of the Methylated Imide: Formation of α-Methyl*cyclo*pentane*-1 : 1-*diacetic Acid.*—(i) *With sulphuric acid.* The imide (87 g.) was dissolved in sulphuric acid (400 c.c.; *d* 1·84), and after remaining over-night, the viscous liquid was cautiously mixed with water (365 c.c.) and boiled under reflux for 8—10 hours. The solution was cooled, diluted with water, saturated with ammonium sulphate, and exhaustively extracted with ether. The ethereal extract was washed with a moderately concentrated solution of

sodium carbonate, from which the acid (55 g.) was recovered in the usual way as a pale yellow oil which rapidly solidified when kept in an evacuated desiccator over sulphuric acid. The residue from the ethereal extract above consisted of a neutral liquid which partly solidified on keeping. The solid product on purification first from alcohol and then from glacial acetic acid was obtained in pearly plates, m. p. 223—224° (Found: C, 59·1; H, 6·1; N, 11·0. $C_{13}H_{16}O_4N_2$ requires C, 59·1; H, 6·1; N, 10·7%). Owing to the small amount available, the constitution of this *substance* could not be determined.

(ii) *With hydrochloric acid.* The imide (5 g.) was heated with concentrated hydrochloric acid (35 c.c.) at 160—180° in a closed tube for 5 hours, and the acid was isolated in the usual way in nearly quantitative yield and of a high degree of purity.

α-*Methyl*cyclo*pentane*-1 : 1-*diacetic acid* crystallises from benzene–light petroleum (b. p. 40—60°) in small, colourless prisms, m. p. 90—91° (Found: C, 60·0; H, 8·1; *M*, 200·2. $C_{10}H_{16}O_4$ requires C, 60·0; H, 8·0%; *M*, 200), readily soluble in acetone, alcohol, ethyl acetate, and ether, moderately soluble in benzene and water, and almost insoluble in hydrochloric acid and light petroleum. A neutral solution of the ammonium salt of the acid gives a bluish-green, crystalline precipitate with copper acetate, a white, crystalline precipitate on boiling with calcium chloride, and a heavy white precipitate with lead acetate. The *silver* salt, prepared in the usual manner, is a white, curdy, insoluble precipitate (Found: Ag, 51·9. $C_{10}H_{14}O_4Ag_2$ requires Ag, 52·2%).

The *anhydride*, prepared by boiling with excess of acetic anhydride, distils at 193°/24 mm. as a colourless liquid, and solidifies to a crystalline cake on cooling. It crystallises from light petroleum (b. p. 40—60°) and chloroform in colourless transparent plates, m. p. 48° (Found: C, 65·9; H, 7·7. $C_{10}H_{14}O_3$ requires C, 65·9; H, 7·7%), and dissolves in aqueous alkali when warmed, the acid (m. p. 90—91°) being deposited on acidification of the solution.

The β-*naphthylamic acid*,

$$C_{10}H_7\cdot NH\cdot CO\cdot CHMe\cdot C(:C_4H_8)\cdot CH_2\cdot CO_2H\ (?),$$

prepared from the anhydride, was obtained as a viscid oil, which solidified in contact with methyl alcohol and separated on recrystallisation in microscopic needles, m. p. 133—134° (Found: C, 73·9; H, 7·4. $C_{20}H_{23}O_3N$ requires C, 73·7; H, 7·1%). The corresponding derivatives of aniline and *p*-toluidine could only be obtained as oils.

The β-*naphthylimide*, obtained by heating the naphthylamic acid to 180° in a test-tube and cooling, was twice crystallised from dilute alcohol (charcoal), and separated in colourless, glistening plates,

m. p. 179° (Found: C, 78·3; H, 6·9. $C_{20}H_{21}O_2N$ requires C, 78·2; H, 6·8%). The *imide*, obtained on heating the dried ammonium salt of the acid in a sealed tube at 150° for 4 hours (Thorpe and Young, J., 1903, **83**, 358), crystallises from boiling water (charcoal) in long, colourless needles, m. p. 123—124° (Found: C, 66·7; H, 8·3; N, 7·9. $C_{10}H_{15}O_2N$ requires C, 66·3; H, 8·3; N, 7·7%); on boiling with a 30% solution of sulphuric acid, it was rapidly hydrolysed, and on extraction of the product with ether, the acid (m. p. 90—91°) was obtained in almost theoretical yield.

B. *Attempts to prepare the Lactone of α-Hydroxy-α'-methylcyclopentane-1 : 1-diacetic Acid* (VI).

Bromination of α-Methylcyclopentane-1 : 1-diacetic Acid.—Since the Hell–Volhard method did not give satisfactory results, the bromination was carried out as follows: The anhydride (6 g.) was treated with the calculated amount of bromine (5·3 g.) and heated in a sealed tube in a boiling water-bath for 5 hours; the liquid was then kept in a desiccator over potash to remove the last traces of hydrobromic acid. The resinous product was dissolved in light petroleum (b. p. 40—60°), and the solution cooled in a freezing mixture. The *bromo-anhydride* (XI) separated in colourless prisms, m. p. 95° (Found: Br, 30·1. $C_{10}H_{13}O_3Br$ requires Br, 30·7%).

Hydrolysis. The crude bromination product was boiled with an excess of 2*N*-sodium carbonate for 10 hours, the solution concentrated, acidified with concentrated hydrochloric acid, and evaporated to dryness, and the residue extracted with ethyl acetate. On removal of the solvent, a thick syrup was obtained which, when kept over sulphuric acid in a vacuum desiccator, began to crystallise. In contact with porous porcelain the mother-liquor was slowly absorbed, and a colourless crystalline residue of the *lactone* of *α-hydroxy-α-methylcyclopentane-1 : 1-diacetic acid* remained; it crystallised from ethyl acetate–light petroleum (b. p. 60—80°) (charcoal) in long, colourless needles, m. p. 140° (Found: C, 60·6; H, 7·0. $C_{10}H_{14}O_4$ requires C, 60·6; H, 7·1%), readily soluble in acetone, chloroform, and ethyl acetate, moderately soluble in benzene, and almost insoluble in light petroleum.

The *silver* salt was obtained from the ammonium salt as a rather soluble, white precipitate (Found: Ag, 35·7. $C_{10}H_{13}O_4Ag$ requires Ag, 35·4%). The *barium* salt, prepared from the lactonic acid by shaking with a suspension of barium carbonate, separated from a fairly concentrated solution in leaflets, which were dried at 110° [Found: Ba, 25·4. $(C_{10}H_{13}O_4)_2Ba$ requires Ba, 25·8%]. The *lead* salt is very soluble. The *ethyl* ester, obtained by saturating an alcoholic solution of the lactonic acid with hydrogen chloride, is a

mobile liquid, b. p. 197°/30 mm. (Found: C, 63·6; H, 8·2. $C_{12}H_{18}O_4$ requires C, 63·7; H, 8·0%).

Bromination of Ethyl Hydrogen α-Methylcyclopentane-1 : 1-diacetate (XXIV).—The *diethyl* ester, prepared by the esterification of the acid with alcohol and sulphuric acid, was obtained as a colourless oil, b. p. 165°/25 mm. (Found: C, 65·8; H, 9·3. $C_{14}H_{24}O_4$ requires C, 65·6; H, 9·4%). This was partly saponified as follows: The ester (25·6 g.) was boiled under reflux with potassium hydroxide (5·6 g.) in alcohol (30 c.c.) for ½ hour, the alcohol evaporated, the residue mixed with water, extracted with ether to remove any neutral product, and the aqueous solution acidified and again extracted with ether. The residual oil was kept in a vacuum desiccator for 2 days. The *silver* salt was obtained as a white precipitate (Found: Ag, 31·8. $C_{12}H_{19}O_4Ag$ requires Ag, 32·2%). The acid ester was warmed with excess of thionyl chloride for ½ hour, and the excess was removed under reduced pressure. The residue was mixed with the required amount of bromine and gently warmed (55°) until all the bromine had disappeared. It was then poured into an excess of ice-cold alcohol, and the mixture allowed to remain over-night. The product, *ethyl α-bromo-α'-methylcyclopentane-1 : 1-diacetate* (XXV), was then collected in ether after the addition of water. The residual oil was dried in a vacuum (Found: Br, 18·2. $C_{14}H_{23}O_4Br$ requires Br, 23·9%). The crude product was hydrolysed by boiling with an aqueous solution of sodium carbonate as described before. The brown oil did not show any tendency to solidify and all attempts to purify the product were fruitless. The oil was oxidised with alkaline permanganate and the resulting product warmed in acetic acid solution with an excess of *o*-phenylenediamine, but no quinoxaline derivative could be isolated.

Bromination of the Methylimide (IX).—A suspension of the methylimide in water was shaken with a slight excess of bromine for 24 hours (compare Gupta and Thorpe, J., 1922, **121**, 1900). The solid *methylimide* of *α-bromo-αα'-dicyano-α'-methylcyclopentane-1 : 1-diacetic acid* (XXVI), when collected and purified from alcohol, separated in colourless needles, m. p. 180° (decomp.) (Found: Br, 24·0. $C_{13}H_{14}O_2N_3Br$ requires Br, 24·7%). Hydrolysis with concentrated hydrochloric acid led to α-methyl*cyclo*pentane-1 : 1-diacetic acid, identified by its m. p. (90—91°) and by direct comparison with a known specimen.

C. *Synthesis of 1-Acetylcyclopentane-1-acetic Acid* (XVI) *and of the Lactone of α-Hydroxy-α-methylcyclopentane-1 : 1-diacetic Acid* (XII).

cyclo*Pentane-1-acetic-1-carboxylic Acid*.—This substance is obtained in excellent yield by the action of potassium cyanide on

ethyl *cyclo*pentylidenecyanoacetate (Harding and Haworth, J., 1910, **97**, 486) under the following conditions (compare Lapworth and McRae, *loc. cit.*). The ester (165 g.) was dissolved in rectified spirit (825 c.c.) to which was added a solution of potassium cyanide (115 g.) in water (260 c.c.). The clear solution was then allowed to stand at the ordinary temperature for about a week, during which a considerable amount of the potassium salt of the condensation product gradually separated. The mixture was evaporated on the steam-bath, and the dark residue then boiled with a large excess of concentrated hydrochloric acid for 6 hours. The solution was cooled and repeatedly extracted with ether, the extract dried, and the solvent removed. The residue of almost colourless solid (120 g.) consisted of nearly pure *cyclo*pentane-1-acetic-1-carboxylic acid, m. p. 156—156·5° (compare Norris and Thorpe, J., 1921, **119**, 1207) (Found: C, 55·8; H, 7·1. Calc.: C, 55·8; H, 7·0%). The *anhydride*, obtained by boiling the acid with acetyl chloride for 2 hours and fractionating under reduced pressure, was a colourless oil, b. p. 154°/20 mm., but it solidified in a freezing mixture and then had m. p. 30° (Found: C, 62·5; H, 6·6. $C_8H_{10}O_3$ requires C, 62·3; H, 6·5%). The *anilic acid*, prepared by mixing cold benzene solutions of the anhydride and aniline and crystallising the precipitated product from 84% alcohol, forms colourless plates, m. p. 167—167·5° (Found: C, 67·5; H, 6·8. $C_{14}H_{17}O_3N$ requires C, 68·0; H, 6·9%). The *anil*, prepared by heating the anilic acid, crystallises from alcohol in glistening prisms, m. p. 127—128° (Found: C, 73·4; H, 6·8. $C_{14}H_{15}O_2N$ requires C, 73·4; H, 6·6%). The *monomethyl* ester (XIV) was obtained by boiling the anhydride (46·2 g.) with methyl alcohol (24·4 c.c.) under reflux for 3 hours, removing excess of methyl alcohol in a vacuum, and crystallising the residue from light petroleum (b. p. 60—80°); it separated as magnificent transparent needles, m. p. 80—81° (Found: C, 58·0; H, 7·5; *M*, 185·5. $C_9H_{14}O_4$ requires C, 58·1; H, 7·5%; *M*, 186). The corresponding acid ethyl ester could not be solidified. The *acid chloride* was prepared by heating the acid ester (38 g.) with freshly distilled thionyl chloride (25 c.c.) at 50—60° in a glycerol-bath for 45 minutes; the excess of thionyl chloride was then removed in a vacuum, and the residue distilled under reduced pressure, giving a colourless oil, b. p. 132°/16 mm. The p-*toluidide* crystallises from dilute methyl alcohol in feathery needles, m. p. 111° (Found: C, 69·6; H, 7·6. $C_{16}H_{21}O_3N$ requires C, 69·8; H, 7·6%).

1-*Acetylcyclopentane*-1-*acetic Acid* (XVI).—The acid chloride described above was diluted with its own volume of dry benzene and gradually added during ¾ hour to a well-cooled solution of zinc methyl iodide prepared from zinc–copper couple (60 g.), methyl

iodide (25 c.c.), benzene (22 c.c.), and dry ethyl acetate (15 c.c.). After standing for an hour, the product was mixed with ice-cold dilute sulphuric acid, the benzene layer removed, washed successively with a 10% solution of potash, saturated ammonium sulphate solution, and water, dried, and distilled. The keto-ester boiled constantly at 121°/9 mm. as a colourless oil having a characteristic ethereal smell, but was not sufficiently pure for analysis; it was therefore hydrolysed to the acid by boiling with alcoholic potash, and this was converted into the sparingly soluble *semicarbazone*, which crystallised from boiling water in long, colourless needles, m. p. 197° (Found: C, 53·3; H, 7·8. $C_{10}H_{17}O_3N_3$ requires C, 52·9; H, 7·5%).

The semicarbazone was gently warmed with dilute hydrochloric acid, the solution extracted with ether, the extract dried with sodium sulphate, and evaporated; the solid residue was recrystallised from light petroleum (b. p. 60—80°) and 1-*acetyl*cyclo*pentane*-1-*acetic acid* was thus obtained in shining plates, m. p. 83—84° (Found: C, 63·5; H, 8·1; *M*, 171. $C_9H_{14}O_3$ requires C, 63·5; H, 8·2%; *M*, 170). The keto-acid, on oxidation with sodium hypobromite, gave an excellent yield of *cyclo*pentane-1-acetic-1-carboxylic acid. The *oxime* crystallised from water in flat needles, m. p. 124—125° (Found: C, 58·2; H, 8·2. $C_9H_{15}O_3N$ requires C, 58·4; H, 8·1%). The *methyl* ester, prepared from the acid in the usual way, was obtained as an oil, b. p. 131°/18 mm. (Found: C, 65·0; H, 8·9. $C_{10}H_{16}O_3$ requires C, 65·3; H, 8·7%); it readily yielded a *semicarbazone*, which separated from alcohol in shining scales, m. p. 152—153° (Found: C, 54·7; H, 7·8. $C_{11}H_{19}O_3N_3$ requires C, 54·8; H, 7·9%). On treatment with dry sodium methoxide (Rothstein and Thorpe, *loc. cit.*, p. 2016), the ester was transformed into a gummy product which readily dissolved in dilute alkali and gave a brownish-violet colour with an aqueous-alcoholic solution of ferric chloride. The substance could not, however, be obtained in a crystalline condition.

Reduction of 1-*Acetyl*cyclo*pentane*-1-*acetic Acid.*—Attempts to reduce the acid by means of sodium amalgam and by hydrogen in presence of platinum-black were unsuccessful, but reduction was ultimately effected as follows: The acid (5 g.) was dissolved in ethyl alcohol (15 c.c.), and sodium (4 g.) introduced in small lumps. The mixture was then heated at 112°, and alcohol (45 c.c.) gradually added during 2 hours. As soon as the last portions of sodium had disappeared, the excess of alcohol was removed in steam, the aqueous solution acidified, extracted with ether, the extract washed with sodium carbonate, dried, and evaporated. The *lactone* (XVII) was obtained on distillation under reduced pressure as a colourless oil, b. p. 132°/15 mm., having a characteristic smell

(Found: C, 69·6; H, 9·0. $C_9H_{14}O_2$ requires C, 70·1; H, 9·1%); $d_4^{15·8°}$ 1·057645, $n_D^{15·8°}$ 1·4742, $[R_L]_D$ 40·9 (calc., 41·0).

Conversion of the Lactone into α-Methylcyclopentane-1 : 1-diacetic Acid.—The lactone (5 g.) was heated with finely powdered 98% potassium cyanide (2·7 g.) in a sealed tube at 260° for 8 hours, and the resulting product acidified and repeatedly extracted with ether; the acidic product was washed out with an aqueous solution of sodium carbonate, and the alkaline solution evaporated to dryness. The residue was then boiled with an excess of 40% sulphuric acid for 3 hours; the acid isolated in the usual way melted at 90—91° and was identified as α-methylcyclopentane-1 : 1-diacetic acid by direct comparison and by the analysis of the silver salt (Found: Ag, 51·8. Calc.: Ag, 52·2%).

Oxidation of Methyl 1-Acetylcyclopentane-1-acetate with Alkaline Permanganate: Formation of α-Ketocyclopentane-1 : 1-diacetic Acid (XIX).—The crude ester (6 g.) was stirred with water (400 c.c.), and to this was gradually added during 6 hours a solution of potassium permanganate (11 g.) and sodium hydroxide (4 g.) in 350 c.c. of water. The colour of the permanganate was slowly discharged, and after remaining for 12 hours, the solution became almost colourless. The filtrate and washings from the manganese precipitate were evaporated to small bulk, again filtered, and acidified with dilute hydrochloric acid. The liberated organic acids were dissolved in ether, and the semi-solid mass which remained on removal of the solvent was dissolved in glacial acetic acid, mixed with an excess of *o*-phenylenediamine, and slowly heated on the steam-bath for ½ hour. Excess of acetic acid was then removed, and the residue mixed with water. The brown, resinous product was collected and freed from impurities by rubbing with ether. The remaining solid was purified by two crystallisations from dilute acetone and thus obtained as a microcrystalline powder, m. p. 221° (Found: C, 66·3; H, 6·4. Calc.: C, 66·2; H, 5·9%). There can be no doubt, therefore, that the product consists of the quinoxaline derivative of α-ketocyclopentane-1 : 1-diacetic acid (Lanfear and Thorpe, *loc. cit.*, p. 1688, give m. p. 222°).

Action of Hydrocyanic Acid on 1-Acetylcyclopentane-1-acetic Acid: Synthesis of the Lactone of α-Hydroxy-α-methylcyclopentane-1 : 1-diacetic Acid (XII).—The keto-acid (10 g.) was mixed with water (25 c.c.), and pure potassium cyanide (30 g.) was added in small quantities at a time, the whole being cooled in a freezing mixture. The clear solution was allowed to stand for about an hour and concentrated hydrochloric acid (44 c.c.) was gradually run in with constant shaking, the temperature being kept below −10°. After 24 hours, more hydrochloric acid was added, and the mixture left

for another day at the ordinary temperature; it was then warmed on the steam-bath for 10 minutes and extracted with ether. The ethereal solution was washed with a solution of sodium carbonate, dried, and evaporated. The residual oil, consisting of nearly pure cyano-lactone, was then hydrolysed with an excess of concentrated hydrochloric acid on the steam-bath. The clear solution was evaporated, and the solid extracted with chloroform or ethyl acetate; the residue which remained after the removal of the solvent crystallised from ethyl acetate and light petroleum (b. p. 60—80°) in long, colourless, flattened needles, m. p. 139—140°. The product was identified with the lactonic acid obtained in the bromination of α-methyl*cyclo*pentane-1 : 1-diacetic acid by direct comparison and by analysis (Found: C, 60·8; H, 7·3. Calc.: C, 60·6; H, 7·1%).

D. *Synthesis of* α-*Methyl*cyclo*pentylideneacetone* (XXVIII) *and of* α-*Methyl*-Δ^1-cyclo*pentenylacetone* (XXX).

α-*Methyl*cyclo*pentylideneacetic Acid* (XXVII).—The condensation of *cyclo*pentanone with ethyl α-bromopropionate and magnesium proceeded readily in benzene solution, giving a 50% yield of ethyl 1-hydroxy-α-methyl*cyclo*pentane-1-acetate, b. p. 130—140°/36 mm. The ester on hydrolysis with 50% alcoholic potash at the ordinary temperature yielded the hydroxy-acid as a viscous oil which showed no tendency to solidify; it was therefore boiled with acetic anhydride, and the mixture distilled in steam; the unsaturated acid, which separated from the distillate as a solid, crystallised from dilute methyl alcohol in needles, m. p. 108—109° (Found, for silver salt: Ag, 43·8. Calc.: Ag, 43·7%). The *acid chloride*, prepared in the usual way with thionyl chloride, distilled as a colourless liquid, b. p. 123°/30 mm.

α-*Methyl*cyclo*pentylideneacetone*.—This ketone was prepared in a good yield by the action of zinc methyl iodide on the foregoing acid chloride. With semicarbazide acetate it readily yielded a *semicarbazone*, of which two different forms were isolated by repeated crystallisation from methyl alcohol. The less soluble separated in rosettes of small crystals, m. p. 189° (Found: C, 61·6; H, 8·8; N, 21·7. $C_{10}H_{17}O_3N$ requires C, 61·5; H, 8·7; N, 21·5%), and the *ketone*, regenerated from it in the usual way, was obtained as a colourless oil, b. p. 108°/27 mm., $d_4^{19·2°}$ 0·960808, $n_D^{19·2°}$ 1·49642, $[R_L]_D$ 41·986 (calc., 41·106) (Found: C, 78·0; H, 10·2. $C_9H_{14}O$ requires C, 78·3; H, 10·1%). The more soluble semicarbazone crystallised from dilute alcohol in colourless, felted needles, m. p. 169° (Found: C, 61·8; H, 8·8; N, 21·6%), and the ketone regenerated from it had b. p. 109°/25 mm., $d_4^{20·3°}$ 0·958084, $n_D^{20·3°}$ 1·49528, $[R_L]_D$ 42·025 (Found: C, 77·9; H, 9·9%). The physical properties of the ketones corresponded well with their αβ-structure.

α-Methyl-Δ¹-cyclopentenylacetic Acid.—The ethyl ester was readily obtained by the dehydration of the hydroxy-ester (above) with the theoretical amount of phosphorus oxychloride in benzene solution; it distilled as a colourless oil with an agreeable smell, b. p. 108—110°/30 mm., $d_4^{17.7°}$ 0·96668, $n_D^{17.7°}$ 1·4583, $[R_L]_D$ 47·45 (calc., 47·37). The acid, prepared from this ester by hydrolysis with alcoholic potash, distilled as a colourless oil, b. p. 150°/28 mm., $d_4^{19.7°}$ 1·050988, $n_D^{19.7°}$ 1·4792, $[R_L]_D$ 37·79 (calc., 38·01) (Found, for Ag salt: Ag, 44·0. Calc.: Ag, 43·7%). A sample did not deposit any crystals during 14 months (compare Wallach, *loc. cit.*). The *acid chloride*, prepared in the usual way, had b. p. 86—88°/20 mm., and on treatment with zinc methyl iodide gave a good yield of the corresponding βγ-ketone. The crude ketone readily yielded a *semicarbazone*, which separated in lustrous plates, m. p. 144°, from dilute alcohol (Found: C, 61·8; H, 8·7; N, 21·8. $C_{10}H_{17}O_3N$ requires C, 61·5; H, 8·7; N, 21·5%), and *α-methyl-Δ¹-cyclopentenylacetone*, regenerated from it by means of oxalic acid, had b. p. 82°/17 mm., $d_4^{20°}$ 0·921922, $n_D^{20°}$ 1·4632, $[R_L]_D$ 41·24 (calc., 41·11) (Found: C, 78·7; H, 10·3. $C_9H_{14}O$ requires C, 78·3; H, 10·1%). The ketones could not be induced to react with ethyl sodiomalonate or sodiocyanoacetate.

The author is greatly indebted to Professor J. F. Thorpe, C.B.E., F.R.S., for his kind interest in the work, to the Trustees of the Palit Fund of the Calcutta University for a scholarship which enabled him to undertake this research, and to the Chemical Society for a grant with which part of the cost has been defrayed. The author also desires to thank Mr. Khuda, of this College, for much assistance in the preparation of initial materials.

CCCXLIV.—*Experiments on the Synthesis of Certain γ-Ketonic Acids Closely Allied to Balbiano's Acid. Part II. Syntheses of αββ- and ααβ-Trimethyllævulic Acids, of the Lactone of α'-Hydroxy-ααβ-trimethylglutaric Acid, and of γ-Keto-αββ-trimethylpropane-αγ-dicarboxylic Acid (Balbiano's Acid).*

By JOGENDRA CHANDRA BARDHAN.

DURING his classical experiments on the oxidation of camphoric acid (*e.g.*, *Rend. Accad. Lincei*, 1892, i, 278: *Ber.*, 1894, **27**, 2133), Balbiano isolated a considerable quantity of a dibasic acid, $C_8H_{12}O_5$,

and an equivalent of oxalic acid, along with small amounts of camphanic, camphoronic, and trimethylsuccinic acids. The new acid, on reduction with hydriodic acid and red phosphorus, yielded a mixture of a monobasic lactonic acid, $C_8H_{12}O_4$, and a dibasic acid, $C_8H_{14}O_4$, which Balbiano considered to be αββ-trimethylglutaric acid because on oxidation it gave *as*-dimethylsuccinic acid. This structure was subsequently confirmed when Perkin and Thorpe synthesised the acid (J., 1899, **75**, 61).

Since the trimethylglutaric acid is also formed from the lactonic acid $C_8H_{12}O_4$ on reduction, the latter might have been either (I) or (II), but Blanc (*Bull. Soc. chim.*, 1901, **25**, 68) synthesised the acid (II) and found it to be different from Balbiano's lactonic acid, which is therefore (I) (compare Pandya and Thorpe, J., 1923, **123**, 2852).

(I.) $CMe_2(-CH\cdot CO_2H)\cdot CHMe\cdot CO\cdot O$ $\qquad$ $CMe_2(\cdot CMe\cdot CO_2H)\cdot CH_2\cdot CO\cdot O$ (II.)

For many years two views were held as to the constitution of the acid $C_8H_{12}O_5$: Balbiano (*Ber.*, 1897, **30**, 289, 1901), as a result of his examination of the reduction products, represented the acid by the oxide formula (III), and suggested that the corresponding dihydroxy-acid was a stage in its formation from camphoric acid; whereas Mahla and Tiemann (*Ber.*, 1895, **28**, 2151) preferred the keto-formula (IV) on account of the fact that the acid, when heated at 160—180°, is completely decomposed with the formation of trimethylsuccinic anhydride and carbon monoxide. These authors could not, however, satisfactorily establish the ketonic character of the acid, and the somewhat ill-defined *p*-bromophenylhydrazone which they prepared proved to be an addition product (compare Balbiano, *loc. cit.*).

More recently, Kon, Stevenson, and Thorpe (J., 1922, **121**, 656) were led to represent the acid in the liquid state or in solution as an equilibrium mixture of the forms (IV) and (V), and this tautomeric structure was further supported by Rothstein, Stevenson, and Thorpe (J., 1925, **127**, 1078). Although it had thus been shown that

(III.) $CH(\cdot CO_2H)\cdot CMe(\cdot CO_2H)$ $\qquad$ (IV.) $CO(\cdot CO_2H)\cdot CMe_2\cdot CHMe\cdot CO_2H$ $\rightleftharpoons$ (V.) $C(OH)(\cdot CO_2H)\cdot CMe_2\cdot O\cdot CHMe\cdot CO$

Balbiano's oxide structure is incorrect, it was still necessary to prove definitely the correctness of the keto-formula, and this has now been achieved by the synthesis of an acid of this structure which is identical with the acid obtained from camphoric acid.

αββ-Trisubstituted ketoglutaric acids are peculiarly difficult to prepare, for the usual methods of synthesis fail, but since it had been

found (preceding paper) that ethyl 1-acetyl*cyclo*pentane-1-acetate on treatment with alkaline permanganate was smoothly oxidised to α-keto*cyclo*pentane-1 : 1-diacetic acid, it appeared possible that the desired ketonic acid might be obtainable by similarly oxidising the acetyl group of αββ-trimethyl-lævulic acid to the $CO{\cdot}CO_2H$ group.

Synthesis of αββ-Trimethyl-lœvulic Acid.—This acid was prepared by the following series of reactions: Trimethylsuccinic anhydride was converted by sodium ethoxide into the half ester (VI), the acid chloride of which reacted with zinc methyl iodide to give the keto-ester (VII) in good yield. This ester, however, contained an

$CMe_2{\cdot}CO_2H$	$CMe_2{\cdot}CO{\cdot}CH_3$	$CMe_2{\cdot}CO_2Et$
$CHMe{\cdot}CO_2Et$	$CHMe{\cdot}CO_2Et$	$CHMe{\cdot}CO{\cdot}CH_3$
(VI.)	(VII.)	(VIII.)

appreciable quantity of the isomeric ester (VIII), evidently derived from the alternative acid ester formed during esterification of the anhydride. A somewhat similar mixture of ketonic esters was also obtained when the acid ester was prepared by the partial saponification of the neutral ester. Bone, Sudborough, and Sprankling's statement (J., 1904, **85**, 536), that they obtained two different acid esters of trimethylsuccinic acid according as they started from the anhydride or the neutral ester, must therefore be regarded as incorrect.

The separation of the pure constituents from the mixture of the corresponding acids thus obtained proved to be very difficult, but was ultimately accomplished by the fractional crystallisation of the mixed semicarbazones from methyl alcohol. The regenerated acids melted at 65—66° and 77—78°, and since they showed mutual depression of m. p. when mixed, there can be no doubt that they are different. Their respective structures were therefore ascertained by effecting a rational synthesis of ααβ-trimethyl-lævulic acid, which proved to be identical with the less fusible acid, so the acid of m. p. 65—66° must be the αββ-isomeride.

Synthesis of ααβ-Trimethyl-lœvulic Acid.—The first experiment to be tried for this purpose was the reaction of ethyl α-bromo*iso*butyrate with ethyl sodiomethylacetoacetate, since it was expected that the condensation product would give the required acid (IX) on hydrolysis:

$$\begin{matrix} CMe_2 & CMe{\cdot}CO{\cdot}CH_3 \\ CO_2Et & CO_2Et \end{matrix} \longrightarrow \begin{matrix} CMe_2{\cdot}CHMe{\cdot}CO{\cdot}CH_3 \\ CO_2H \end{matrix} \quad \text{(IX.)}$$

but the condensation did not proceed in the expected manner, and all efforts to obtain this acid from the products of the reaction were fruitless.

It was then thought possible that methylmesityl oxide might react with hydrocyanic acid according to the method of Lapworth

(J., 1904, **85**, 1216) to give a product which on hydrolysis should furnish the desired keto-acid :

$$CMe_2{:}CMe{\cdot}CO{\cdot}CH_3 \longrightarrow CMe_2(CN){\cdot}CHMe{\cdot}CO{\cdot}CH_3 \longrightarrow \text{(IX.)}$$

Although methylmesityl oxide was readily synthesised from trimethylacrylic acid (Blaise reaction), it reacted with hydrocyanic acid with such reluctance under the usual conditions that after prolonged heating there was obtained a considerable quantity of a stable cyanohydrin (X), evidently produced by the further action of hydrocyanic acid on the mononitrile first formed; traces of the expected acid (IX) were isolated in the form of its semicarbazone, but in insufficient quantity for characterisation.

The cyanohydrin (X) on hydrolysis yielded a nitrogenous *substance* (XI), closely analogous to mesitylic acid prepared by Pinner (*Ber.*, 1881, **14**, 1075) and by Lapworth (*loc. cit.*) from mesityl oxide by a somewhat similar process.

$CMe_2(CN){\cdot}CHMe{\cdot}CMe(OH){\cdot}CN$ (X.)

$CMe_2{\cdot}CHMe{\cdot}CMe{\cdot}CO_2H$ / CO———NH (XI.)

Ultimately the following method was devised and found to give the desired synthesis. Methyl ethyl ketone was condensed with ethyl α-bromo*iso*butyrate and zinc, a good yield of *ethyl β-hydroxy-ααβ-trimethyl-*n*-valerate* (XII) being obtained. This hydroxy-ester on dehydration with phosphorus pentoxide yielded *ethyl ααβ-trimethyl-Δ$^{\beta}$-pentenoate* (XIII), the structure of which was established by oxidation with ozone, one of the products being acetaldehyde. When the corresponding *acid* was treated with bromine, it gave a somewhat unstable dibromide (XIV), which at the moment of its formation partly eliminated hydrobromic acid with the production of the bromo-lactone (XV) (compare Perkin and Smith, J., 1904, **85**, 157); but on distillation of the crude bromination product under the ordinary pressure, a considerable evolution of hydrobromic acid took place, and the chief product was the unsaturated *lactone* (XVI). This was finally hydrolysed by means of alcoholic potash to *ααβ-trimethyl-lævulic acid* (IX), presumably through the intermediate stage shown.

(XII.) $CMe_2{\cdot}CMe(OH){\cdot}CH_2$ / CO_2Et $\quad CH_3$ $\longrightarrow$ $CMe_2{\cdot}CMe{:}CH$ / CO_2Et $\quad CH_3$ (XIII.)

(XV.) $CMe_2{\cdot}CMeBr{\cdot}CHMe$ / CO———O $\longleftarrow$ $CMe_2{\cdot}CMeBr{\cdot}CHBrMe$ / CO_2H (XIV.)

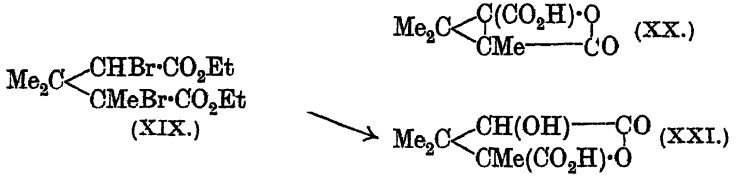
(XVI.) $CMe_2{\cdot}CMe{:}CMe$ / CO———O $\longrightarrow$ $[CMe_2{\cdot}CMe{:}CMe$ / CO_2H $\quad OH]$ $\longrightarrow$ (IX.)

In spite of the many stages involved in the above synthesis, the yield of the keto-acid was quite good. The synthetic acid agreed in all its properties with the acid, m. p. 77—78°, prepared from trimethylsuccinic anhydride (above).

Synthesis of Balbiano's Acid.—αββ-Trimethyl-lævulic acid was readily oxidised by alkaline permanganate to γ-keto-αββ-trimethylpropane-αγ-dicarboxylic acid. The acid thus obtained melted at the same temperature as Balbiano's acid, and showed no depression of m. p. when mixed with an equal quantity of the acid obtained from camphoric acid (kindly lent by Professor Thorpe). The identity of the synthetic acid was also established by the preparation of its quinoxaline derivative, and by its conversion into αββ-trimethylglutaric acid by means of hydriodic acid and red phosphorus. Finally, the synthetic acid when heated is converted into trimethylsuccinic acid with evolution of carbon monoxide.

The synthesis of Balbiano's acid just described is consistent only with the keto-formula, and the solid acid most probably exists in this form; this follows, not only because Balbiano's acid does not give ψ-esters corresponding to the lactol form (compare for instance, opianic acid, phthalonic acid, and the semi-aldehyde of trimethylsuccinic acid), but also because on treatment with acetic anhydride it forms a normal anhydride (Balbiano, *Ber.*, 1897, **30**, 1902) and not an acetyl derivative.

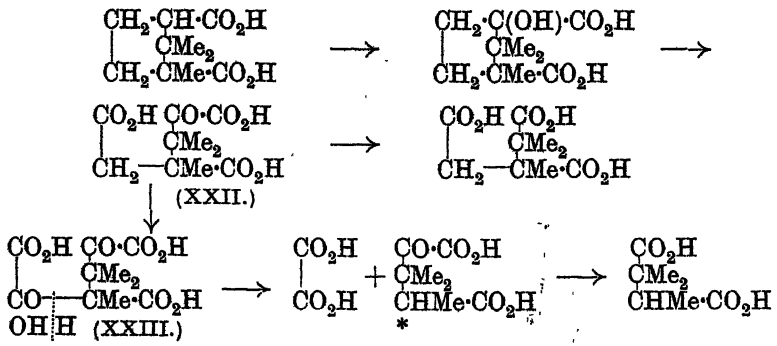
In the light of the keto-formula, the anhydride of the acid should be represented by (XVII) (compare 3 : 4-dimethoxyphthalonic anhydride; Kuroda and Perkin, J., 1923, **123**, 2094). The anhydride reacts normally with β-naphthylamine, giving a crystalline naphthylamic acid (XVIII), which does not react with *o*-phenylenediamine.



XVII.) $\begin{matrix} CMe_2\text{–}CO\text{–}CO \\ | \quad\quad | \\ CHMe\cdot CO\cdot O \end{matrix}$ ⟶ $\begin{matrix} CMe_2\cdot CO\cdot CO\cdot NH\cdot C_{10}H_7 \\ | \\ CHMe\cdot CO_2H \end{matrix}$ (XVIII.)

The formation of an acid of the keto-formula from camphoric acid is somewhat remarkable. Kon, Stevenson, and Thorpe (*loc. cit.*) suggested the following mechanism of its formation, starting from αα′-dihydroxy-αββ-trimethylglutaric acid, which, according to Balbiano, constitutes the first step in the oxidation of camphoric acid:

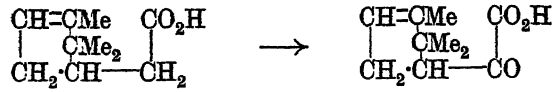
$$Me_2C\begin{matrix}CH(OH)\cdot CO_2H \\ CMe(OH)\cdot CO_2H\end{matrix} \rightarrow Me_2C\begin{matrix}C(OH)\cdot CO_2H \\ CMe\cdot CO_2H\end{matrix} \rightarrow Me_2C\begin{matrix}CO\cdot CO_2H \\ CHMe\cdot CO_2H\end{matrix}$$



In spite of the apparent simplicity of this explanation, the issue is not in reality quite so clear, for it has been shown by Pandya and Thorpe (*loc. cit.*) that the dibromo-ester (XIX) on treatment with alkali passes into a mixture of the lactonic acids (XX) and (XXI),

from which no trace of any keto-acid can be obtained. Since the dihydroxytrimethylglutaric acids, which are presumably formed in these reactions, show no tendency whatever to pass into a hydroxy-*cyclo*propane acid, it follows that Balbiano's acid cannot be formed from camphoric acid by way of dihydroxytrimethylglutaric acid.

Quite apart from this, it is difficult to understand why camphoric acid, which is such an exceedingly stable substance, should undergo oxidative fission at those bonds which would have to be ruptured in order to give this dihydroxyglutaric acid—a mode of oxidation which suggested to Balbiano his oxide structure.



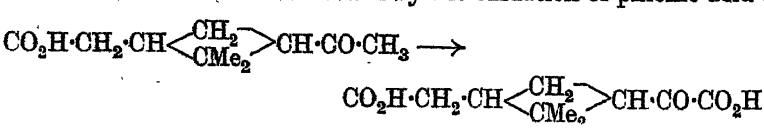
There is, however, no need to assume the formation of a dihydroxyglutaric acid. An adequate explanation is provided for the formation, not only of the keto-acid, but also of the accompanying camphanic, camphoronic, and trimethylsuccinic acids, if it be assumed that the oxidation of camphoric acid proceeds through the following stages:

A similar mechanism has been postulated by Bredt (*Ber.*, 1893, **26**, 3050) in order to explain the formation of camphoronic acid from camphoric acid by oxidation with nitric acid, but there is a difference between the two cases in that the intermediate keto-acid (XXII) is somewhat stable towards alkaline permanganate and is not therefore broken down into camphoronic acid to any large extent; on the contrary it is oxidised at the methylene group and the resulting diketo-acid (XXIII) is hydrolysed as shown above.

The formation of an α-ketonic acid by the direct oxidation of an acetic acid residue is not without precedent, for Chandrasena and

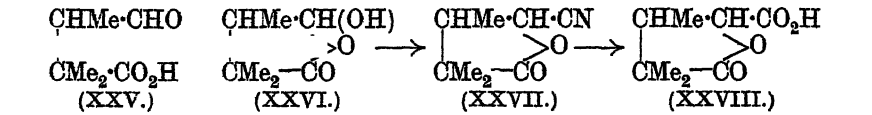
Ingold (J., 1922, **121**, 1553) have shown that α-campholenic acid on treatment with mild oxidising agents gives a keto-acid as the principal product:

Owing to the obvious difficulty of devising suitable experiments, it has not been found possible definitely to establish the correctness of the mechanism suggested above. It is hoped, however, that the experiments on the oxidation of camphanic, dehydrocamphoric, and camphoronic acids, which are now in hand, will throw further light on the matter.



The keto-acid contains an asymmetric carbon atom (marked *) and would therefore be expected to exist in one inactive and two active modifications. The acid actually isolated by Balbiano from *d*-camphoric acid was, however, inactive. This is to be expected, for examination of the scheme above shows that during the hydrolysis of the diketo-acid (XXIII) a new asymmetric carbon atom is being produced, and consequently the resulting product should be inactive owing to the formation in equal quantities of the two optically enantiomorphous forms. The case of camphoronic acid is somewhat different because it still retains one of the asymmetric carbon atoms originally present in the camphoric acid.

Balbiano (*Ber.*, 1899, **32**, 1022) apparently succeeded in resolving his acid, $C_8H_{12}O_5$, by a fractional crystallisation of its quinine salts, but the rotations, $[\alpha]_D$ + 5·48° and − 3·35°, which he found for the two active forms are far from satisfactory. Experiments are now being undertaken to prepare the two active modifications of the acid from the *d*- and *l*-modifications of trimethylsuccinic acid by applying the same scheme as has been used for the synthesis of the inactive acid.



During the course of the foregoing experiments a considerable quantity of ααβ-trimethyl-lævulic acid had accumulated, and it seemed of interest to investigate whether on oxidation with alkaline permanganate it would give the keto-acid

$$CO_2H\cdot CMe_2\cdot CHMe\cdot CO\cdot CO_2H \quad \text{(XXIV.)},$$

but it was found to yield only trimethylsuccinic acid. This is somewhat remarkable, especially as Baeyer, in the course of the oxidation of pinene, isolated an appreciable quantity of a keto-acid which he considered to be formed by the oxidation of pinonic acid:

Attempts were also made to prepare the keto-acid (XXIV) by the oxidation of the lactonic acid (XXVIII), which was obtained in good yield by the action of hydrocyanic acid on the lactone (XXVI) (Blaise and Courtout, *Bull. Soc. chim.*, 1902, **35**, 998), followed by the hydrolysis of the lactonic nitrile (XXVII) with the aid of concentrated hydrochloric acid, the reaction probably taking place through the tautomeric aldehyde-form (XXV). Theoretically, the

(XXV.) (XXVI.) (XXVII.) (XXVIII.)

lactonic acid should exist in two inactive forms, but only one has yet been isolated. On treatment with alkaline permanganate, the lactonic acid passes into trimethylsuccinic acid, no trace of the desired keto-acid being formed, although Balbiano's lactonic acid (I) under similar conditions furnishes the keto-acid (IV). Further experiments for the synthesis of the keto-acid are in progress.

EXPERIMENTAL.

Preparation of Trimethylsuccinic Acid.—At the commencement of this research most of the trimethylsuccinic acid was prepared according to the method of Bone and Sprankling (J., 1899, **75**, 862). It was subsequently found, however, that Higson and Thorpe's method (J., 1906, **89**, 1466) was by far the best for obtaining the acid in quantity.

The condensation of acetonecyanohydrin with ethyl sodiocyanoacetate is best carried out as follows: A suspension of the sodio-derivative of ethyl cyanoacetate, prepared from sodium (30 g.), alcohol (480 c.c.), and cyanoacetic ester (155 c.c.), was gradually added with vigorous shaking to a solution of freshly distilled acetonecyanohydrin (118 g.) in 80 c.c. of alcohol, cooled in ice. The product was kept in ice for 12 hours and then at the ordinary temperature for 2 days. The viscous mass was mixed with methyl iodide (90 c.c.) and gently heated under reflux until neutral; the ethyl αβ-dicyano-αββ-trimethylpropionate, b. p. 159—162°/25 mm., isolated in the usual way, was hydrolysed by 12 hours' boiling with seven times its volume of concentrated hydrochloric acid, thus giving an almost quantitative yield of trimethylsuccinic acid, which had m. p. 149° after one crystallisation from dilute hydrochloric acid.

The anhydride, prepared by boiling the acid with an excess of acetyl chloride, is best purified by distillation under reduced pressure from a Claisen flask provided with a fractionating side arm. It is obtained as a colourless oil, b. p. 110°/10 mm., which on cooling

solidifies to a crystalline mass (Found: C, 58·8; H, 7·3. Calc.: C, 59·2; H, 7·0%).

Synthesis of αββ-Trimethyl-lævulic Acid (formula as VII).—*Action of sodium ethoxide on trimethylsuccinic anhydride.* To the anhydride (35·5 g.), dissolved in absolute alcohol (120 c.c.) and cooled in a freezing mixture, was gradually added a solution of sodium ethoxide (sodium, 5·75 g.; alcohol, 144 c.c.) so that the temperature did not rise above 0°; after 2—3 hours the excess of alcohol was distilled off under reduced pressure at 40°. The solid residue was dissolved in water, and the solution extracted with ether to remove any neutral ester. The aqueous solution was slightly acidified with dilute sulphuric acid, and the liberated oil collected in ether. On drying and distilling off the ether, a viscous oil remained which did not solidify in a vacuum, and when cooled in a freezing mixture passed into a thick jelly-like mass (Found, in silver salt: Ag, 38·8. Calc.: Ag, 38·4%). It decomposed on distillation under reduced pressure (compare Bone, Sudborough, and Sprankling, *loc. cit.*, p. 551).

The acid ester (42 g.) was warmed with freshly distilled thionyl chloride (25 c.c.) in a glycerol-bath at 55°, and excess of thionyl chloride was removed under diminished pressure. The residual oil was dissolved in an equal volume of dry benzene, and the solution gradually added to a solution of zinc methyl iodide, prepared by heating over-night a mixture of zinc copper couple (60 g.), benzene (30 c.c.), methyl iodide (30 c.c.), and ethyl acetate (15 c.c.); the mixture was vigorously shaken and kept at 0° during the reaction, and then allowed to attain the ordinary temperature (1 hour). Dilute sulphuric acid was added, the benzene layer separated, washed successively with dilute caustic potash solution, water, and saturated ammonium sulphate solution, dried, and the solvent removed. The residue on distillation under diminished pressure boiled constantly at 113°/18 mm., giving a colourless oil with a terpene-like smell. Preliminary examination showed this to consist of a mixture of several substances, which were separated as follows: The oil (30 g.) was heated under reflux for 1 hour with a solution of potassium hydroxide (30 g.) in water (30 c.c.) and methyl alcohol (60 c.c.); the excess of alcohol was evaporated, the residue extracted with ether to remove unchanged ester, the aqueous solution acidified, again extracted with ether, and the solvent removed. The residual oil (24 g., moist) was dissolved in water (30 c.c.) and the solution gently warmed on the steam-bath for ½ hour with the addition of semicarbazide hydrochloride (15 g.), sodium acetate (30 g.), and water (60 c.c.). On standing at the ordinary temperature for 20 hours, a considerable amount of a crystalline semicarbazone separated; this

was collected and the filtrate extracted several times with ether, dried, and evaporated, giving an oil which, when purified in the usual way, proved to be trimethylsuccinic acid.

The crude semicarbazone was repeatedly crystallised (at least 20 times) from methyl alcohol, whereby two fractions were obtained, m. p.'s 174° and 155°, together with a large middle fraction melting indefinitely between 160—168°, from which no definite product could be isolated. The *semicarbazone*, m. p. 155°, is readily soluble in methyl alcohol and crystallises in minute, colourless prisms (Found : C, 50·1; H, 7·9. $C_9H_{17}O_3N_3$ requires C, 50·2; H, 7·9%).

The pure semicarbazone (17 g.) was heated on the steam-bath with concentrated hydrochloric acid (25 c.c.) and water (25 c.c.) until the crystals had entirely disappeared. The product was then extracted with ether and dried. The residue obtained on evaporation of the ether readily solidified in an evacuated desiccator to a crystalline mass (10 g.). (It is essential that the semicarbazone used be very pure; otherwise the acid is obtained as a gum which is difficult to purify.)

αββ-*Trimethyl-lævulic acid* crystallises from light petroleum (b. p. 40—60°) in clusters of flattened prisms, m. p. 65—66° (Found : C, 60·9; H, 8·9. $C_8H_{14}O_3$ requires C, 60·8; H, 8·9%), moderately soluble in most solvents. The *ethyl* ester, prepared from the pure acid by Phelp and Tillotson's alcohol-vapour method, had b. p. 110°/14 mm., $d_4^{19°}$ 0·981537, $n_D^{19°}$ 1·43638, $[R_L]_D$ 49·6 (calc., 50·0) (Found : C, 64·3; H, 9·8. $C_{10}H_{18}O_3$ requires C, 64·5; H, 9·7%).

The less soluble *semicarbazone* crystallises from methyl alcohol in beautiful iridescent prisms, m. p. 174° (Found : C, 50·2; H, 7·7. $C_9H_{17}O_3N_3$ requires C, 50·2; H, 7·9%). When this was treated with dilute hydrochloric acid, as described for the other semicarbazone, αα*β-trimethyl-lævulic acid* was obtained as an oil which gradually solidified to a hard crystalline mass; it was purified by careful evaporation of its ice-cold solution in ethyl bromide–light petroleum (b. p. 40—60°), and thus obtained in minute, transparent prisms, m. p. 77—78° (mixed m. p. with αββ-trimethyl-lævulic acid, 52°) (Found : C, 60·8; H, 8·9. $C_8H_{14}O_3$ requires C, 60·8; H, 8·9%). Its constitution follows from its rational synthesis (see below).

Oxidation of αββ-Trimethyl-lævulic Acid with Sodium Hypobromite.—The pure acid (1 g.) was dissolved in aqueous caustic potash, cooled to 0°, and mixed with a solution of potassium hypobromite, prepared from bromine (1 c.c.), potassium hydroxide (2·5 g.), and water (45 c.c.). After remaining for 3 hours, the liquid was treated with sulphur dioxide, strongly acidified with dilute sulphuric acid, and extracted with ether. The dried extract on evaporation left a solid residue which was identified as trimethylsuccinic acid by its m. p. and by direct comparison.

Attempted Synthesis of ααβ-Trimethyl-lævulic Acid (IX).

Trimethylacrylic Acid.—Ethyl β-hydroxy-αββ-trimethylpropionate was prepared by the condensation of acetone with ethyl α-bromopropionate and zinc in accordance with the directions of Perkin and Thorpe (J., 1896, **69**, 1482), and obtained as a colourless oil, b. p. 99°/28 mm. The low-boiling fractions on distillation at the ordinary pressure yielded an appreciable amount of mesityl oxide. The hydroxy-ester (32 g.) was gradually mixed with phosphorus pentachloride (50 g.), and the clear liquid gently heated on the steam-bath for 1 hour. After being cooled, the product was poured into ice-water, the oil extracted with ether, and the solvent evaporated. The residue was hydrolysed by boiling with an excess of alcoholic potash, and after removal of the excess of alcohol, the solution was acidified, extracted with ether, the extract dried, and the ether evaporated. On distillation, αββ-trimethylacrylic acid was obtained as a colourless oil, b. p. 114—115°/27 mm., which partly solidified on cooling, and was recrystallised from methyl alcohol; colourless plates, m. p. 70—71° (Found: C, 63·1; H, 8·8. Calc.: C, 63·2; H, 8·8%).

Methylmesityl Oxide.—αββ-Trimethylacrylyl chloride, b. p. 144—145°/766 mm. (compare Perkin and Thorpe, *loc. cit.*, p. 1480), was treated with zinc methyl iodide in the usual way and the ketone isolated and distilled (b. p. 145°); its *semicarbazone* separated from dilute alcohol in colourless plates, m. p. 186° (Found: C, 57·3; H, 8·9. $C_8H_{15}ON_3$ requires C, 56·8; H, 8·9%). Methylmesityl oxide condensed with malonic ester under the following conditions: A solution of ethyl sodiomalonate (sodium, 1·15 g.; absolute alcohol, 14 c.c.; ethyl malonate, 8·5 g.) was heated under reflux with methylmesityl oxide (5·6 g.) for 18 hours; the excess of alcohol was distilled off, the mixture diluted with water (100 c.c.), and the neutral products were extracted with ether. The aqueous solution was then mixed with potassium hydroxide (4·5 g.), the whole boiled for 15 minutes, acidified with dilute sulphuric acid, and boiled until no more carbon dioxide was evolved; the yellow oil which separated solidified on cooling and was crystallised from water (charcoal) with the addition of a few drops of alcohol. The colourless needles, m. p. 100—101°, were evidently trimethyldihydroresorcinol (compare Crossley, J., 1901, **79**, 141) (Found: C, 70·1; H, 9·3. Calc.: C, 70·1; H, 9·1%).

Action of Potassium Cyanide on Methylmesityl Oxide.—Attempts to condense the ketone with 1 mol. of hydrocyanic acid were fruitless, for its reaction with 2 mols. could not be prevented. The ketone (11·2 g.) was dissolved in alcohol (75 c.c.), and the solution boiled under reflux with potassium cyanide (26 g. in 78 c.c. of water)

for 4 hours. The mixture was evaporated on the steam-bath, and the viscous product boiled with a large excess of concentrated hydrochloric acid. The excess of acid was then removed, and the solid residue mixed with water and filtered. The solid (XI) was crystallised (charcoal) from acetic acid, separating in colourless, silky needles, m. p. 238° (decomp.) (Found: C, 58·4; H, 8·1. $C_9H_{15}O_3N$ requires C, 58·4; H, 8·1%), easily soluble in glacial acetic acid, moderately soluble in boiling acetone, and sparingly soluble in other organic solvents. The compound was acidic, and resembled mesitylic acid in its general properties.

The aqueous filtrate (above) was repeatedly extracted with ether, and the extract dried and evaporated; the oily residue readily gave a crystalline semicarbazone, which separated from alcohol in colourless, shining prisms, m. p. 175° (decomp.) (Found: C, 50·5; H, 8·1. $C_9H_{17}O_3N_3$ requires C, 50·2; H, 7·9%). There can be no doubt that this is the semicarbazone of ααβ-trimethyl-lævulic acid, but owing to the small yield the solid acid could not be obtained from it.

Synthesis of ααβ-Trimethyl-lævulic Acid.

Ethyl β-*Hydroxy*-ααβ-*trimethyl*-n-*valerate* (XII).—A mixture of dry methyl ethyl ketone (55 g.), ethyl α-bromo*iso*butyrate (150 g.), benzene (300 c.c.), and zinc turnings (60 g.) was boiled under reflux on the steam-bath for ½ hour. Minute quantities of iodine were then added until the reaction started. The flask was removed from the steam-bath and the vigorous reaction allowed to proceed by its own heat, the mixture being finally heated on the steam-bath for 15 minutes. *Ethyl* β-*hydroxy*-ααβ-*trimethyl*-n-*valerate* was isolated from the mixture and purified in the usual way, being obtained as a colourless, mobile oil, having a faint ethereal smell (yield, 55%), b. p. 92°/11 mm. (Found: C, 63·5; H, 10·2. $C_{10}H_{20}O_3$ requires C, 63·8; H, 10·6%).

ααβ-*Trimethyl*-Δ^{β}-*pentenoic Acid* (formula as XIII).—The hydroxy-ester (68 g.) was mixed with phosphorus pentoxide (40 g.) under dry benzene (75 c.c.), and the mixture was slowly distilled under ordinary pressure until most of the benzene had passed over. The distillation was then continued under reduced pressure and a considerable amount of a low-boiling fraction collected; on redistillation, almost the whole fraction boiled at 100—102°/45 mm., giving the *ester* (XIII) as a colourless, transparent oil, having a sweet smell; $d_4^{16\cdot8°}$ 0·906942, $n_D^{16\cdot8°}$ 1·43878, $[R_L]_D$ 49·3 (calc., 49·5) (Found: C, 70·1; H, 10·8. $C_{10}H_{18}O_2$ requires C, 70·6; H, 10·6%). A chloroform solution of the ester was ozonised and then gave a good yield of acetaldehyde, identified as ethylidene-β-dinaphthyl oxide, m. p. 170° (mixed m. p. with an authentic specimen 171°).

The ester was hydrolysed with 10% methyl-alcoholic potash, and the resulting *ααβ-trimethyl-Δ$^{\beta}$-pentenoic acid* had b. p. 113°/10 mm., $d_4^{19\cdot2°}$ 0·963434, $n_D^{19\cdot2°}$ 1·45283, $[R_L]_D$ 39·8 (calc., 40·2) (Found, for *silver* salt: Ag, 43·8. $C_8H_{13}O_2Ag$ requires Ag, 43·4%); the *p-toluidide*, prepared from the acid chloride and *p*-toluidine, crystallised from light petroleum (b. p. 40—60°) in long, silky needles, m. p. 71° (Found: C, 77·9; H, 9·0. $C_{15}H_{21}ON$ requires C, 77·9; H, 9·1%).

Lactone of γ-Hydroxy-ααβ-trimethyl-Δ$^{\beta}$-pentenoic Acid (XVI).—The foregoing acid was dissolved in dry carbon disulphide, and to the solution, cooled to 0°, a slight excess of bromine was added. After remaining in the cold for a few hours, the solvent was removed. The solid residue thus obtained could not be purified owing to the ease with which it lost hydrobromic acid. The crude product was therefore distilled from a glycerol-bath; a considerable evolution of hydrobromic acid took place, and between 210° and 260° (bath temperature) a large amount of brown oil distilled over. This was collected in ether, washed with a dilute solution of sodium carbonate, dried with sodium sulphate, evaporated, and the residue distilled under reduced pressure. After several distillations, a considerable amount of a low-boiling fraction (b. p. 75—80°/13 mm.) was isolated, together with a small amount of a higher-boiling fraction (b. p. 110°/13 mm.) which still contained some bromine and was not further investigated. The first fraction was again washed with sodium carbonate, dried, and distilled, the *lactone* being obtained as a colourless, halogen-free liquid, b. p. 80°/13 mm., having a characteristic burning smell (Found: C, 68·7; H, 8·8. $C_8H_{12}O_2$ requires C, 68·6; H, 8·6%).

ααβ-Trimethyl-lævulic Acid (IX).—The unsaturated lactone was boiled under reflux with 20% methyl-alcoholic potash for 2 hours. The alcohol was evaporated, the residue acidified, and extracted six times with ether; when freed from solvent, ultimately in a vacuum desiccator over sulphuric acid, the acid was obtained as a colourless solid, m. p. 77—78° after recrystallisation from ethyl bromide–light petroleum (b. p. 60—80°) (Found: C, 60·7; H, 9·0. Calc. for $C_8H_{14}O_3$: C, 60·8; H, 8·9%), and was identical in all essential respects with the acid obtained previously (p. 2613), giving a semicarbazone, m. p. 173° (Found: C, 50·6; H, 7·9. Calc.: C, 50·2; H, 7·9%).

The *p-nitrophenylhydrazone* forms yellow, flattened needles, m. p. 207° (with previous softening), showing slight dichroism (Found: C, 57·2; H, 6·5. $C_{14}H_{19}O_4N_3$ requires C, 57·3; H, 6·5%). The *piperonylidene* derivative crystallises from dilute alcohol (charcoal) in lemon-yellow needles, m. p. 115° (Found: C, 66·2; H, 6·1. $C_{16}H_{18}O_5$ requires C, 66·2; H, 6·2%).

Synthesis and Properties of γ-Keto-αββ-trimethylpropane-αγ-dicarboxylic Acid (Balbiano's Acid) (IV).

Oxidation of αββ-Trimethyl-lævulic Acid.—To a mixture of αββ-trimethyl-lævulic acid (5 g.), potassium hydroxide (2 g.), and water (200 c.c.), was added a solution of permanganate (12 g.) and caustic potash (4 g.) in 300 c.c. of water, the mixture being cooled in running water. In the course of 2—3 hours the colour of the permanganate disappeared, and after a further 12 hours the greenish liquid became practically colourless. The manganese precipitate was collected and washed several times with hot water, and the combined aqueous filtrates were concentrated, cooled, acidified with hydrochloric acid, and extracted with ether. The solid residue (3·5 g.), which remained after removal of the last traces of ether in a vacuum desiccator, was exactly neutralised with caustic soda, mixed with a 30% solution of calcium chloride, filtered, and the clear solution boiled on a sand-bath for 1 hour. The crystalline precipitate which separated on cooling was collected, washed, suspended in water, and decomposed with concentrated hydrochloric acid in presence of an excess of ether. The ethereal layer was separated, washed, dried with anhydrous sodium sulphate, and evaporated. On being kept in a desiccator, the residue solidified to a snow-white, crystalline mass, which melted at 119° after having been rubbed with a little chloroform, and consisted of pure Balbiano's acid (Found: C, 51·1; H, 6·5. Calc.: C, 51·0; H, 6·4%). The identity was further established by direct comparison with an authentic specimen of the acid prepared from camphoric acid and by the following characteristic reactions.

(1) *Formation of quinoxaline derivative.* A considerable quantity of this substance accumulated in the course of the preliminary experiments on the oxidation of trimethyl-lævulic acid and its ethyl ester.* The crude acid resulting from the oxidation was mixed with an excess of *o*-phenylenediamine and glacial acetic acid and gently warmed on the steam-bath for ½ hour; excess of acetic acid was removed, and addition of a large excess of water then precipitated a solid which crystallised from methyl alcohol (charcoal) in magnificent shining plates, m. p. 223—224° with previous softening (mixed m. p. with an authentic specimen 223—224°; compare Kon, Stevenson, and Thorpe, *loc. cit.*) (Found: C, 64·5; H, 6·5. Calc.: C, 64·6; H, 6·2%).

* Owing to the extraordinary ease with which ethyl αββ-trimethyl-lævulate is hydrolysed by alkali, twice the theoretical quantity of permanganate must be used when this ester is employed in the synthesis of Balbiano's acid, as otherwise the alcohol produced reduces the whole of the permanganate, leaving the lævulic acid practically unchanged.

(2) *Formation of αββ-trimethylglutaric acid.* The synthetic acid (2 g.) was heated with hydriodic acid (12 c.c., *d* 1·9) and red phosphorus (1 g.) for 15 hours in a closed tube at 150—160°. The colourless solution was extracted with ether and the solid residue from the extract was dissolved in ammonia and boiled with a solution of calcium chloride. The precipitated calcium salt was collected and decomposed with dilute hydrochloric acid; the free acid, isolated in the usual way, crystallised from dilute hydrochloric acid in glistening prisms, m. p. 86—87° (Found: C, 55·4; H, 8·2. Calc.: C, 55·2; H, 8·1%).

(3) *Formation of trimethylsuccinic acid.* The crude oxidation acid was heated in a sulphuric acid bath, the melt extracted with boiling water, and the succinic acid isolated and purified in the form of its calcium salt; after one crystallisation from dilute hydrochloric acid it melted at 148° (compare Mahla and Tiemann, *loc. cit.*) (Found: C, 52·4; H, 7·5. Calc.: C, 52·5; H, 7·5%).

The following experiments were made with a specimen of Balbiano's acid prepared from camphoric acid by oxidation with alkaline permanganate (Balbiano, *loc. cit.*; Rothstein, Stevenson, and Thorpe, *loc. cit.*). The yield of the keto-acid is considerably reduced if the temperature is allowed to rise above 30°. The acid was isolated as the characteristic calcium salt and purified in the usual way.

The anhydride (XVII) was prepared by the following modification of Balbiano's method: The acid (5 g.) was boiled under reflux with acetic anhydride (20 c.c.) for 2 hours, the excess of acetic anhydride was removed under reduced pressure, and the residue kept in a desiccator. Since the product did not show any tendency to solidify, its constitution was confirmed by conversion into a crystalline naphthylamic acid by dissolving it in benzene and boiling the solution under reflux with a slight excess of β-naphthylamine for ½ hour. It was then diluted with ether and washed with dilute hydrochloric acid and water. The naphthylamic acid (XVIII) was dissolved in sodium carbonate and precipitated with dilute acid; it crystallised from dilute methyl alcohol (charcoal) in colourless, shining scales, m. p. 177° (decomp.), and behaved on titration as a monobasic acid (Found: C, 68·8; H, 6·3; *M*, 315. Calc.: C, 69·0; H, 6·1%; *M*, 313). It does not condense with *o*-phenylenediamine, and decomposes on heating with the formation of resinous products.

Action of Alkali on Balbiano's Acid.—The acid (5 g.) was boiled with a solution of potassium hydroxide (60 g.) in water (40 c.c.) for 3 hours, the product cooled in ice, acidified with hydrochloric acid, and extracted several times with ether. On evaporation of the solvent, a solid (3·9 g.) remained, which was proved to be unchanged

Balbiano's acid by its m. p. (119°) and by the formation of the quinoxaline derivative (m. p. 223—224°). Under the above conditions, therefore, Balbiano's acid remains practically unchanged and does not show any tendency to pass into a hydroxy*cyclo*propane acid.

Reduction with Sodium Amalgam.—The acid (5 g.) was dissolved in sodium carbonate and mechanically stirred with 300 g. of 3% sodium amalgam; the solution was concentrated, cooled, acidified with dilute hydrochloric acid, and extracted with ether. The residue from the ethereal extract was neutralised with alkali and boiled with a solution of calcium chloride to remove any unchanged keto-acid. The clear filtrate was acidified with hydrochloric acid and extracted with ether. The residue from evaporation of the extract was repeatedly crystallised from ethyl acetate–light petroleum (b. p. 60—80°) and yielded the expected lactonic acid in flattened needles, m. p. 163° (Found: C, 56·0; H, 7·3. Calc.: C, 55·8; H, 7·0%).

Attempt to Prepare the Keto-acid (XXIV).—The oxidation of ααβ-trimethyl-lævulic acid (IX) was carried out in an exactly similar manner to that of αββ-trimethyl-lævulic acid and appeared to proceed as before, but the product did not condense with *o*-phenylenediamine, and after recrystallisation from dilute hydrochloric acid it was identified as trimethylsuccinic acid, m. p. 149°.

Condensation of Chloroacetic Ester with Dimethylacetoacetic Ester.—Since a considerable amount of dimethylacetoacetic ester had accumulated in course of the preparation of ααβ-trimethylglutaconic acid, which had been used in unsuccessful efforts to prepare the lactone (XXVIII) by reduction, an attempt was made to convert it into the semi-aldehyde of trimethylsuccinic acid (XXV) by condensation with chloroacetic ester and sodium ethoxide (Darzens, *Compt. rend.*, 1904, **139**, 1215), followed by hydrolysis and distillation of the resulting oxidic ester, $CO_2Et\cdot CMe_2\cdot CMe\cdot CH\cdot CO_2Et$.
$\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\quad O$

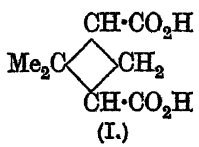
A mixture of dimethylacetoacetic ester (80 g.) and chloroacetic ester (90 g.) was cooled in a freezing mixture, and finely powdered sodium ethoxide (50 g.) added in small quantities with vigorous shaking. After remaining at the ordinary temperature over-night, the mixture was heated on the steam-bath for 5 hours. The dark-coloured mass was then mixed with water and extracted with ether. The ethereal extract was washed with sodium carbonate, dried, and evaporated. On distillation the residue gave a considerable amount of unchanged dimethylacetoacetic ester in the low-boiling fractions, and subsequently the oxidic *ester* was obtained as a colourless liquid, b. p. 162°/26 mm. (yield, 30%) (Found: C, 58·6; H, 7·8. $C_{12}H_{20}O_5$ requires C, 59·0; H, 8·2%). This ester on hydrolysis and

distillation yielded an extremely viscous oil, which did not give any semicarbazone and is still under investigation.

Synthesis of the Lactonic Acid (XXVIII).—Preliminary attempts were made to prepare this acid from ααβ-trimethylglutaric acid, but the latter could not be obtained in suitable condition either by Perkin and Thorpe's method (J., 1896, **69**, 1187), by catalytic reduction of the corresponding glutaconic acid, or by the condensation of *iso*butaldehyde with ethyl ethylidenemalonate. Ultimately, however, the semi-aldehyde of trimethylsuccinic acid was prepared by Blaise and Courtout's method (*loc. cit.*), and, although it exists in the lactol form (XXVI), it was found to condense with hydrocyanic acid, thereby enabling the synthesis to be effected as follows: A mixture of the semi-aldehyde (5 g.), potassium cyanide (98%, 9·2 g.), and water (15 c.c.) was cooled in a freezing mixture, and to it was gradually added (2 hours) the calculated amount of concentrated hydrochloric acid (11·5 c.c.); after remaining in the cold over-night, the mixture was warmed on the steam-bath with the addition of hydrochloric acid (5 c.c.). The resulting oil was collected in ether, washed with dilute sodium carbonate, dried, and the ether distilled off. The residue of almost pure *cyano-lactone* (XXVII) was hydrolysed with concentrated hydrochloric acid, and the clear solution extracted several times with ether. Removal of the solvent left an oil which slowly solidified to a crystalline mass, and repeated crystallisation from toluene gave the *lactone* of *α′-hydroxy-ααβ-trimethylglutaric acid* in stellate clusters of fan-shaped needles, m. p. 110° (Found: C, 55·5; H, 7·0. $C_8H_{12}O_4$ requires C, 55·8; H, 7·0%). The mother-liquor from the crystallisation yielded on evaporation a gum which was not further investigated. On oxidation with alkaline permanganate the lactonic acid gave trimethylsuccinic acid as the sole product.

αα-Dihydroxy-ββ-dimethylglutaric Acid.—This substance was prepared by the oxidation of ββ-dimethyl-lævulic acid with alkaline permanganate. The crude product, which was obtained as a gum, was dissolved in ammonia, and the sparingly soluble calcium salt precipitated by warming with a solution of calcium chloride. The acid was regenerated with dilute hydrochloric acid and extracted with ether. The solid residue, purified by repeated crystallisation from chloroform, was obtained in silky needles, m. p. 82–83° (Found: C, 43·9; H, 6·4. Calc.: C, 43·7; H, 6·3%); the identity of this substance with αα-dihydroxy-ββ-dimethylglutaric acid (Perkin and Thorpe, J., 1901, **79**, 757) was established by direct comparison and by a mixed m. p. This shows, therefore, that the method by which Balbiano's acid has been synthesised is a very general one.

I take this opportunity of expressing my indebtedness to Professor J. F. Thorpe, F.R.S., for his kind interest in the work and for the encouragement I have received from him. I am also indebted to the Trustees of the Palit Fund of the Calcutta University for a Foreign Scholarship, and to the Chemical Society for a grant for which grateful acknowledgments are made.



IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY,

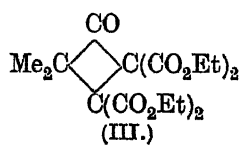
CCCXLV.—*Attempts to Synthesise Norpinic Acid.*



By GEORGE ROGER CLEMO and KENNETH NORMAN WELCH.

SINCE norpinic acid, one of the key compounds of terpene chemistry, was given the constitution (I) by Baeyer (*Ber.*, 1896, **29**, 1907), numerous unsuccessful attempts at its synthesis have been made. The claim of Ganguly (*J. Indian Inst. Sci.*, 1922, 23) must be included in this category, since, although it has only been possible to refer to an abstract of the paper, this states definitely that Ganguly's experiment cannot be regarded as successful. The following is a brief account of synthetic work designed to achieve this end, in which results of interest have been obtained although final success has not been reached. The continued inability to synthesise this acid is not easy to understand from Ingold's modification of the Baeyer strain theory (J., 1915, **107**, 197, 1082), in view of the fact that *cyclo*butane-1 : 3-dicarboxylic acid is easily prepared (Perkin and Simonsen, J., 1909, **95**, 1171).

The first synthetic method to be tried was to prepare (II) by condensing dimethylketen with maleic or fumaric ester. On hydrolysis, this should lose carbon dioxide, and the cyanohydrin of the resulting keto-acid by treatment with hydrobromic acid followed by the replacement of the bromine atom by hydrogen should yield (I).

(I.)

(II.)

(III.)

Only polymerised dimethylketen and unchanged ester, however, could be isolated from the reaction mixture, even when one or both of the reagents were produced *in situ*, and therefore presumably in an active phase, as by the action of a mixture of zinc and copper powder on an ethereal solution of α-bromo*iso*butyryl bromide and αβ-dibromosuccinic ester. Likewise, condensation could not be

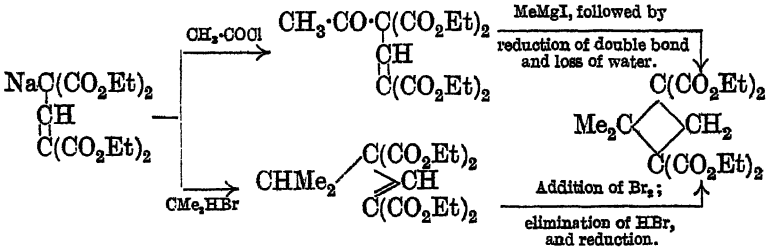
effected between α-bromo*iso*butyryl bromide and sodioethane-tetracarboxylic ester to give the compound (III).

The preparation of ethyl αα-dimethyltricarballylate,

$$CMe_2(CO_2Et)\cdot CH(CO_2Et)\cdot CH_2\cdot CO_2Et,$$

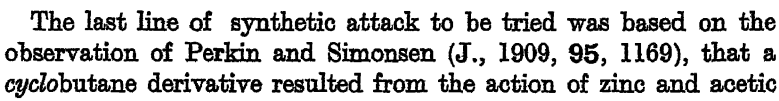
was then investigated with a view to carrying out the Dieckmann reaction on it to give (II). The corresponding acid has been obtained by the oxidation of pinic acid (Tiemann and Semmler, *Ber.*, 1895, **28**, 1349), of dihydroxycamphoceanic acid (Jagelki, *Ber.*, 1899, **32**, 1509), and of fenchone (Gardner and Cockburn, J., 1898, **73**, 708), and also synthetically from ethyl α-bromo*iso*butyrate and ethyl sodiocyanosuccinate, followed by hydrolysis. It was thought, however, that it might be easily prepared from the more accessible bromoacetic ester and sodio-αβ-dicyano*iso*valeric ester, which is readily obtained by the action of acetonecyanohydrin on sodium cyanoacetic ester (Higson and Thorpe, J., 1906, **89**, 1455). In spite of the fact, however, that a much improved method for the preparation of acetonecyanohydrin has been worked out, the poor yields of dimethyltricarballylic acid thus obtained render it impracticable to prepare thus the necessary amount for the full investigation of this synthetic method.

Attention was then directed to the action of formaldehyde and its derivatives on *iso*propylidenedimalonic ester, $CMe_2[CH(CO_2Et)_2]_2$, which has been prepared from *iso*propylidenemalonic ester (Kötz, *J. pr. Chem.*, 1907, **75**, 494). The latter ester has been prepared by condensing acetone with malonic ester in the presence of acetic anhydride and zinc chloride (Meyenberg, *Ber.*, 1895, **28**, 786), and by modifying this method we have consistently obtained yields of 50%. It has not been found possible, however, to obtain the yields of *iso*propylidenedimalonic ester claimed by Kötz, whose method is inconvenient on a large scale; yields of 10% were obtained by forming the sodiomalonic ester and carrying out the condensation in alcoholic solution in sealed tubes, but the bulk of the *iso*propylidenemalonic ester was recovered unchanged. Eventually, however, 10 g. of *iso*propylidenedimalonic ester were accumulated, but when its sodio-derivative was treated with methylene iodide, *iso*propylidenemalonic ester and a higher-boiling compound, apparently methylenedimalonic ester, resulted instead of the expected *cyclo*butane derivative. These results can be explained on the assumption that the Michael reaction is reversible (Ingold and Powell, J., 1921, **119**, 1976).



Acting on this basis, we attempted to condense methoxymethylmalonic ester with *iso*propylidenemalonic ester to give

$$CH(CO_2Et)_2\cdot CMe_2\cdot C(CO_2Et)_2\cdot CH_2\cdot OMe,$$



since if this ester were formed it could lose methyl alcohol with the

formation of the *cyclo*butane derivative and thus force the balanced Michael reaction to completion. No condensation, however, could be effected.

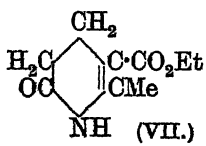
It was then decided to make sodio-$\alpha\gamma$-dicarbethoxyglutaconic ester (Conrad and Guthzeit, *Annalen*, 1884, **222**, 250) the starting point for the synthetic schemes :

The first method broke down, however, for the acetyl chloride reacted with the sodio-derivative in the enol phase, and the resulting *O*-acetyl compound then lost ethyl acetate to give ethyl ethoxy-α-pyrone-dicarboxylate (IV), a compound previously described by Guthzeit and Dressel (*Ber.*, 1889, **22**, 1415). Since the second part of this scheme was investigated, an account of a similar reaction with *iso*propyl iodide has been published by Hariharan, Menon, and Simonsen (this vol., p. 431), but as our results throw some light on this peculiar reaction they are worth mentioning. In addition to the trimesic ester obtained by these authors, it has been found that a considerable quantity of malonic ester is present in the reaction mixture. This result indicates hydrolysis at the double bond in the first instance, followed by the loss of carbon dioxide as sodium carbonate and subsequent formation of trimesic ester by the well-known reaction from formylacetic ester.

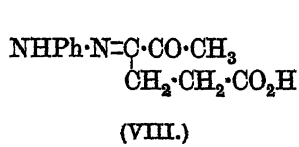
The last line of synthetic attack to be tried was based on the observation of Perkin and Simonsen (J., 1909, **95**, 1169), that a *cyclo*butane derivative resulted from the action of zinc and acetic acid on the compound (V). An attempt was made, therefore, to prepare (VI) from ethyl α-acetylglutarate by the action of magnesium methyl iodide, followed by the replacement of the hydroxyl group by bromine, and subsequent bromination. Acetylglutaric ester has now been prepared in good yield from β-chloropropionic ester and sodioacetoacetic ester. Magnesium methyl iodide reacts, however, with the enol phase of this ester with evolution of methane, and

α-acetylglutaric ester was recovered on acidification of the reaction mixture (compare Grignard, *Compt. rend.*, 1902, **134**, 849).

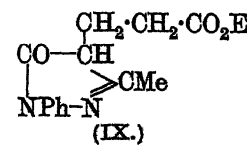
It was attempted to overcome this difficulty by preparing *ethyl α-bromo-α-acetylglutarate*, but the reaction with magnesium methyl iodide, in which iodine was eliminated, proved to be anomalous and resulted in the reduction of the bromo-ester to α-acetylglutaric ester.



α-Acetyl-α-methylglutaric ester was then prepared in the hope that the methyl group would prevent both enolisation and reduction, but on treatment with the Grignard reagent the acetyl group was eliminated to give α-methylglutaric ester (compare Grignard, *loc. cit.*).



In the course of some of the above reactions it became necessary to prove the presence of α-acetylglutaric ester as an end product, and accordingly a search was made for crystalline derivatives for the purpose of characterisation. When the ester is heated with aniline, diphenylcarbamide results, whilst treatment with gaseous ammonia in the cold in the presence of a trace of iodine gives *ethyl α-(α'-aminoethylidene)-glutarate*,



$$CH_3{\cdot}C(NH_2){:}C(CO_2Et){\cdot}CH_2{\cdot}CH_2{\cdot}CO_2Et,$$

which on heating loses alcohol and forms the lactam (VII) (Emery, *J. Amer. Chem. Soc.*, 1891, **13**, 352).

The action of benzenediazonium chloride on α-acetylglutaric ester under the conditions of the Japp–Klingemann reaction gave *α-carboxypentane-γδ-dione-γ-phenylhydrazone* (VIII), whereas treatment of the ester with phenylhydrazine gave the *pyrazolone* (IX).

(VII.)

(VIII.)

(IX.)

Experimental.

αα-Dimethyltricarballylic Acid.—Acetonecyanohydrin (10 g.) (see note, this vol., p. 2629) was condensed with sodiocyanoacetic ester (from cyanoacetic ester, 12 g.) in the manner of Higson and Thorpe (*loc. cit.*). The sodio-αβ-dicyano*iso*valeric ester thus formed was refluxed with bromoacetic ester (20 g.) until neutral. Water was then added, the oil extracted with ether, the extract separated, dried, and fractionated, a considerable proportion of αβ-dicyano*iso*valeric ester being recovered unchanged, together with 2 g. of material, b. p. above 160°/14 mm. This fraction was hydrolysed by refluxing with concentrated hydrochloric acid; the solution was evaporated and the acid extracted with ether, and on evaporation of the ether

a syrup remained which partly crystallised on standing to give αα-dimethyltricarballylic acid, m. p. 149°.

iso*Propylidenemalonic Ester*.—Malonic ester (130 g.), acetic anhydride (120 g.), and a solution of zinc chloride (8 g.) in acetone (110 g.) were heated in thick sealed bulb-tubes in the water-bath for 80 hours. The reaction mixture was added to an equal volume of water and left for 24 hours with occasional shaking to decompose unchanged acetic anhydride. The ester was then separated, the aqueous layer extracted with ether, the extract added to the ester, and dried over sodium sulphate. After removal of the ether the residue was fractionated four times, giving 90 g. of *iso*propylidenemalonic ester, b. p. 116—120°/14 mm. (Found: C, 59·8; H, 8·0. Calc.: C, 60·0; H, 8·0%).

iso*Propylidenedimalonic Ester*.—*iso*Propylidenemalonic ester (20 g.) was heated in alcoholic solution with an equivalent of sodiomalonic ester in a sealed tube in a water-bath for 24 hours. The alcohol was then removed, dilute sulphuric acid added, and the separated oil extracted with ether and distilled. The distillate, b. p. above 160°/14 mm., was refractionated, yielding 3 g. of *iso*propylidenedimalonic ester, b. p. 155°/1 mm. This was refluxed until neutral with two equivalents of sodium ethoxide and excess of methylene iodide in alcoholic solution, the product poured into water, extracted with ether and fractionated; *iso*propylidenemalonic ester passed over at 100—120°/14 mm., and a small quantity of methylenedimalonic ester above 160°/14 mm., as proved by hydrolysis to an acid, m. p. 97° (glutaric acid has m. p. 97·5°).

Condensation of Sodio-αγ-dicarbethoxyglutaconic Ester with Acetyl Chloride. Ethyl Ethoxy-α-pyronedicarboxylate (IV).—Sodiodicarbethoxyglutaconic ester (6 g.; vacuum-dried over sulphuric acid), anhydrous ether (20 c.c.), and redistilled acetyl chloride (2 g.) were introduced into a small flask, the neck of which was immediately sealed, and allowed to stand for 5 days with occasional shaking. The ethereal solution was then filtered from sodium chloride and evaporated on the water-bath. As the last traces of ether were being removed a distinct smell of ethyl acetate was noticed. When an attempt was made to distil the residue in a vacuum, decomposition occurred and the distillate, b. p. 180—200°/3 mm., partly solidified in the receiver. The compound crystallised from benzene–light petroleum in colourless needles, m. p. 94°, not depressed by admixture with an authentic specimen of the pyrone (IV).

Action of iso*Propyl Bromide on Sodiodicarbethoxyglutaconic Ester*.—Sodiodicarbethoxyglutaconic ester (6 g.), alcohol (20 c.c.), and *iso*propyl bromide (1·8 g.) were heated in a sealed tube at 150° for 12 hours. When the tube was opened an inflammable gas (? propane)

ene) was evolved, and when the alcoholic solution was decanted from the mixture of sodium bromide and carbonate, and a small volume of water was added, a solid separated. This having been collected, more water was added to the filtrate. The resulting oil was extracted with ether and fractionated, giving 2 g. up to 100°/3 mm., 0·5 g. from 100—180°/3 mm., and 1 g. above 180°/3 mm. The last fraction partly solidified and, together with the solid collected initially, was recrystallised from alcohol and found to be trimesic ester, m. p. 131° (Found: C, 61·4; H, 6·1. Calc. for $C_{15}H_{18}O_6$: C, 61·2; H, 6·1%). On redistillation, the first fraction boiled at 80°/14 mm., and on treatment with aqueous-alcoholic ammonia gave malonamide, m. p. 171°, mixed m. p. with an authentic specimen 171°.

α-Acetylglutaric Ester.—To a cooled solution of sodium (6 g.) in alcohol (150 c.c.), acetoacetic ester (33 g.) was added, followed, after cooling, by β-chloropropionic ester (35 g.), and the mixture was refluxed for 3 hours on the water-bath. The excess of alcohol was then removed, water added to the residue, and the oil extracted with ether and fractionated; after a small quantity of acetoacetic ester had passed over, ethyl α-acetylglutarate (40 g.; 70%), b. p. 145—147°/12 mm., was obtained (Found: C, 57·5; H, 8·1. Calc. for $C_{11}H_{18}O_5$: C, 57·4; H, 7·8%), giving a deep blue coloration with ferric chloride. In addition, a small higher-boiling fraction of ethyl γ-acetylpentane-αγε-tricarboxylate passed over finally.

Action of Magnesium Methyl Iodide on α-Acetylglutaric Ester.—The Grignard reagent from 5 g. of methyl iodide was dropped into α-acetylglutaric ester (7 g.) in ether (50 c.c.), and the mixture kept over-night. Dilute sulphuric acid was then added, and the ethereal layer distilled, but the ester was recovered unchanged.

α-Bromo-α-acetylglutaric Ester.—As a result of many experiments the following method was adopted as the only one to give satisfactory yields of the bromo-ester: α-Acetylglutaric ester (11·5 g.) was shaken with water (15 c.c.) and calcium carbonate (2·5 g.), and bromine was added drop by drop; the first 0·5 c.c. was rapidly absorbed, presumably by the enol phase of the ester, but further quantities of 0·5 c.c. reacted slowly, the mixture being kept cool and stirred, and the reaction appeared to be complete when 2·7 c.c. had been absorbed during the course of a week. The mixture was then extracted with ether and fractionated, the *bromo*-compound (13 g.) passing over at 162—165°/14 mm. (Found: C, 42·2; H, 5·7. $C_{11}H_{17}O_5Br$ requires C, 42·7; H, 5·5%). The compound gives no coloration with ferric chloride.

Action of Magnesium Methyl Iodide on α-Bromo-α-acetylglutaric Ester.—The Grignard reagent from methyl iodide (5·6 g.) was dropped

into α-bromo-α-acetylglutaric ester (10 g.) in ether (100 c.c.); a pale brown solid separated and the mixture was left over-night and then decomposed by adding ammonium chloride solution. The ethereal layer, which on evaporation in the cold gave no coloration with ferric chloride, was dried, the ether removed, and the residue distilled in a vacuum; iodine was evolved, and the distillate after treatment with caustic soda solution was proved to be α-acetylglutaric ester by the ferric chloride colour reaction, and by conversion into the amino-derivative (see below).

α-Acetyl-α-methylglutaric Ester.—This ester was prepared in 60% yield by the condensation of β-chloropropionic ester and methylacetoacetic ester as described above for α-acetylglutaric ester.

Action of Magnesium Methyl Iodide on α-Acetyl-α-methylglutaric Ester.—The Grignard reagent from methyl iodide (3·5 g.) was dropped into α-acetyl-α-methylglutaric ester (6 g.) in ether (15 c.c.) and refluxed for 7 hours. On being worked up in the usual manner, the main fraction boiled at 120—140°/15 mm. and redistilled at 122—125°/15 mm., and was therefore ethyl α-methylglutarate (Found: C, 59·4; H, 8·6. Calc.: C, 59·4; H, 8·9%).

Ethyl α-(α'-Aminoethylidene)glutarate.—Gaseous ammonia was passed into α-acetylglutaric ester (5 g.), containing a little iodine, for 4 days. Water separated, and on cooling, the product solidified. It was collected, dried on porous plate, and when crystallised from light petroleum (b. p. 40—60°) by spontaneous evaporation gave large colourless prisms, m. p. 37° (Found: C, 57·8; H, 8·1. $C_{11}H_{19}O_4N$ requires C, 57·7; H, 8·3%). When this compound was heated to 190—220°, alcohol was eliminated and the lactam (VIII) formed, m. p. 156° (Found: C, 58·9; H, 6·9. Calc. for $C_9H_{13}O_3N$: C, 59·9; H, 7·1%).

Action of Aniline on α-Acetylglutaric Ester.—Aniline (1 g.), α-acetylglutaric ester (2·5 g.), and a trace of iodine were heated on an oil-bath at 140—160° for 4 hours. On cooling, the product solidified, and after recrystallisation from methyl alcohol gave slightly brown needles, m. p. 238°, not depressed by admixture with a pure specimen of *s*-diphenylcarbamide.

α-Carboxypentane-γδ-dione-γ-phenylhydrazone (*γδ-Diketohexoic Acid γ-Phenylhydrazone*).—α-Acetylglutaric ester (4·7 g.), dissolved in a solution of caustic potash (2·4 g.) in water (9 c.c.), was kept for 24 hours in a corked flask. Water (30 c.c.), acetic acid (3 c.c.), and ice were then added, the solution was vigorously stirred, and benzenediazonium chloride (from aniline, 2 g.), together with an excess of sodium acetate, added immediately. Carbon dioxide was evolved and a flesh-coloured solid separated, which after standing over-night was collected, dissolved in sodium carbonate solution,

and boiled with charcoal. The *phenylhydrazone* was reprecipitated by the addition of hydrochloric acid, and crystallised from alcohol, giving pale yellow needles, m. p. 178° (yield 80%) (Found: C, 61·6; H, 6·0. $C_{12}H_{14}O_3N_2$ requires C, 61·5; H, 6·0%); the highly crystalline *sodium* salt is sparingly soluble in cold water.

Ethyl 1-Phenyl-3-methyl-5-pyrazolone-4-β-propionate.—α-Acetylglutaric ester (10 g.), phenylhydrazine (4 g.), and acetic acid (1 drop) were mixed and allowed to stand for 3 hours. Ether was then added and the solution dried with sodium sulphate. The ether was removed and the residue heated on the water-bath for 10 hours and then distilled, giving the *pyrazolone* as a pale yellow oil, b. p. 215°/3 mm. (Found: C, 65·7; H, 6·55. $C_{15}H_{18}O_3N_2$ requires C, 65·7; H, 6·6%).

NOTES.

Note on an Improved Method of Preparing Selenophen. By HENRY VINCENT AIRD BRISCOE, JOHN BUTTERY PEEL, and PERCY LUCOCK ROBINSON.

IN the preparation of selenophen by heating selenium at 400° in a current of acetylene, considerable quantities of benzene and other hydrocarbons are also formed (Briscoe and Peel, this vol., p. 1741). By the following modification, however, the proportion of these inconvenient by-products may be greatly diminished. Selenium, in portions of 5 g., is heated in an inclined Pyrex tube, closed at the lower end, and provided with an axial inlet tube delivering acetylene some inches above the selenium and well below a side tube leading to a condenser. The middle of the tube is heated to redness, and the selenium is slowly vaporised by heating it from the surface downwards. The first evidence of reaction is the flashing of the acetylene (compare Peel and Robinson, this vol., p. 2068) with deposition of carbon, and thereafter a liquid condensate is formed at the rate of 3—4 c.c. in 4 hours. As in the previous experiments, the reaction proceeds more smoothly if the selenium is mixed with the carbonaceous residue from previous runs.

About 135 c.c. of the crude brown oil thus produced were fractionally distilled through a 4-foot, glass, bead-filled column and a 1-foot, glass, spiral column for the more volatile and the less volatile fractions respectively, and yielded (i) 20 c.c. of benzene, b. p. 80°; (ii) 80 c.c. of selenophen, b. p. 110°; (iii) 10 c.c. of liquid hydrocarbons, b. p.

110—120°; (iv) 10 c.c. of liquid hydrocarbons, b. p. 150—180°; (v) 10 g. of naphthalene; and (vi) 4 c.c. of a green liquid containing selenium.

The last fraction, on microfractional distillation, gave as the middle fraction a sky-blue liquid, b. p. about 240—250°, containing about 20% of selenium, which was probably an impure specimen of selenophten, the analogue of thiophten.

Acknowledgment is made of a grant from the Research Fund of Armstrong College enabling one of us (J. B. P.) to take part in this work.—UNIVERSITY OF DURHAM, ARMSTRONG COLLEGE, NEWCASTLE-ON-TYNE. [*Received, August 10th*, 1928.]

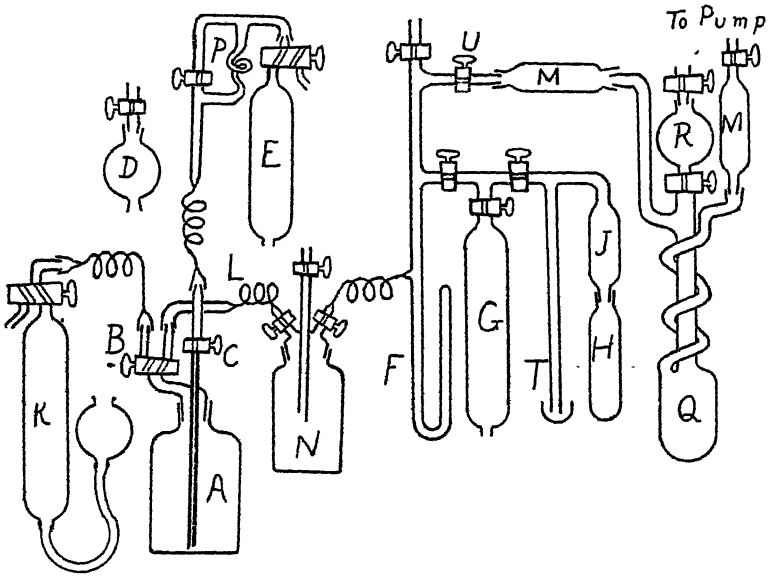
The Preparation of Acetonecyanohydrin. By KENNETH NORMAN WELCH and GEORGE ROGER CLEMO.

ACETONECYANOHYDRIN has been prepared from anhydrous hydrogen cyanide and acetone (Urich, *Annalen*, 1872, **164**, 255), and also by the action of potassium cyanide on acetone sodium bisulphite (Bucherer and Grolée, *Ber.*, 1906, **39**, 1225). The latter method is commonly given in text-books, but it has not been found possible to obtain the yields claimed, on account of the decomposition during distillation of the highly coloured, crude, reaction product. This decomposition appears to be due mainly to impurities which catalyse the following balanced reaction in the forward direction: $CMe_2(OH)CN \rightleftharpoons CMe_2O + HCN$. Moreover, a considerable amount of a solid residue always remains in the distillation flask.

The following simple method does not need anhydrous hydrogen cyanide, and is also free from the above-mentioned objection. Acetone (29 g.) is added to a solution of potassium cyanide (31 g.) in water (100 c.c.). Sulphuric acid (167 g.; 30% H_2SO_4 by weight), is then added slowly with constant stirring, the temperature being kept below 20° by the addition of ice, which also, by diluting the solution, prevents it from becoming unstirrable on account of the separation of potassium hydrogen sulphate. The reaction mixture is then extracted three times with ether, the extract dried over sodium sulphate, the bulk of the ether removed on the water-bath, and the residue rapidly distilled in a vacuum, whereupon acetonecyanohydrin (32 g.) passes over at 81°/15 mm. The compound thus prepared is much more stable than that obtained by Bucherer's method (*loc. cit.*), but even so, it is advantageous to distil it rapidly.—ARMSTRONG COLLEGE, NEWCASTLE-ON-TYNE. [*Received, July 7th*, 1928.]

Apparatus for Chromic Anhydride Oxidations. By WALLACE FRANK SHORT.

DURING the course of some experiments on the oxidation of diphenylmethane derivatives in acetic acid solution, it was found that addition of a concentrated aqueous solution of chromic acid caused the separation of unoxidised material from solution and retarded the reaction. On the other hand, addition of solid chromic anhydride resulted in poor yields of the substituted benzophenones, since they were partly destroyed under these conditions by further oxidation. Addition of an acetic acid solution of chromic anhydride produced the desired result, but the volume of the solution was inconveniently large on account of the comparatively small solubility of the anhydride. This difficulty was overcome by allowing the anhydride to dissolve in the acetic acid returning to the reaction flask from the reflux condenser. For this purpose, a modification of the apparatus designed by Walker (J., 1892, **61**, 717) for the preparation of ethyl iodide was employed. The apparatus (figured in $\frac{1}{4}$ natural size) was mounted in a cork in the flask containing an acetic acid solution of the substance to be oxidised, and was provided with a reflux condenser. The constriction in the chromic anhydride reservoir had an internal diameter of approximately 2 mm., and was loosely plugged with glass wool. The introduction of the oxidising agent may be controlled by regulating the boiling of the acetic acid solution in the flask.



The apparatus may also be employed for the preparation of alkyl iodides by Walker's method (*loc. cit.*) and for the oxidation of organic substances by potassium permanganate in aqueous or acetone solution.—UNIVERSITY COLLEGE, AUCKLAND, NEW ZEALAND. [*Received, August 2nd,* 1928.]

CCCXLVI.—*The Reaction between Nitrous Acid and Hydrogen Sulphide.*

By LANCELOT SALISBURY BAGSTER.

THE precise nature of the products of reaction between nitrous acid and hydrogen sulphide solutions has not been well defined. Divers (J., 1887, **51**, 48) found ammonia and oxides of nitrogen but no hydroxylamine when a mixture of alkali nitrite and sulphide was acidified. By reaction between hydrogen sulphide and the less

FIG. 1.

soluble nitrites (such as that of silver), he obtained some hydroxylamine, an intermediate silver compound being postulated to account for its formation. A simpler explanation of this reaction is now offered.

In the course of the present work the concentration of the solutions was found to have a pronounced effect on the nature of the products, and hydroxylamine was formed under certain conditions.

EXPERIMENTAL.

In order to study the effect of very dilute nitrous acid and at the same time to obtain sufficient product for examination, an apparatus (Fig. 1) was constructed to allow of the slow passage of measured volumes of nitric oxide into a vessel containing hydrogen

sulphide solution and oxygen. The reaction vessel, *A*, of 450 c.c. capacity, was suspended on a stirrup in a thermostat at 30°, and a rocking motion was imparted to it by means of an arm projecting vertically from the stirrup and connected with a pin on a motor-driven pulley. A ground cap carried a two-way tap, *B*, for exhaustion or for admission of oxygen and hydrogen sulphide. A single-way tap, *C*, on a tube projecting into the vessel served to admit solutions or nitric oxide as required. The tube reached the bottom of the vessel for solutions, but was cut off above the liquid level for admission of nitric oxide. Connexions for transference of gases were made by flexible glass spirals with ground joints. Solutions were admitted to *A* from *D* which fitted to a double grinding on *C*.

One arm of the tap *B* led to a manometer, *F*, and a T-piece connecting with a Toepler pump and a system for generating and storing oxygen. The hard-glass tube, *H*, connected by a ground joint, contained potassium permanganate from which oxygen was generated by heat after exhaustion of the system with the mercury pump. The oxygen passed through a soda–lime tube, *J*, and was collected in the graduated holder, *G*, by displacement of mercury, the first portion generated being rejected through the mercury trap, *T*.

Nitric oxide was prepared by dropping concentrated sodium nitrite solution into a sulphuric acid solution of ferrous sulphate. The gas was passed through concentrated sodium hydroxide solution and then over solid hydroxide before collection in the graduated vessel, *E*. Glass connexions with ground joints were used. The generating apparatus was exhausted through the three-way tap on *E* and filled with nitric oxide several times before the collection of gas. The nitrite solution in the dropping funnel was exhausted to remove dissolved air.

Hydrogen sulphide was prepared by saturating magnesium hydroxide suspension in water with the gas obtained from ferrous sulphide, exhausting the solution to remove dissolved gases and then displacing the hydrogen sulphide by heat. The gas after passage through phosphoric oxide was condensed by liquid air, the container then being attached to the graduated reservoir, *K*, by a short, mercury-sealed, rubber joint, and the air removed from the container by a Geryk pump through the two-way tap. About one-quarter of the hydrogen sulphide was allowed to boil off through a mercury trap, and the gas was then collected in *K* by mercury displacement, leaving a considerable portion of residual liquid.

In carrying out an experiment, the vessel *A* was given a preliminary exhaustion by a Geryk pump through all the taps to free the barrels from air. The connecting spiral, *L*, was then fitted, and

the vessel *A* and the connecting leads to the oxygen reservoir exhausted by the mercury pump; 50 c.c. of water or *N*/20-hydrochloric acid solution, previously freed from air by exhaustion in *D*, were run into *A*. Any trace of dissolved gas was carried over by the flow of water vapour to the phosphoric oxide tubes, *MM*, attached to the mercury pump. The tap *B* was then closed, and the pentoxide tubes allowed to absorb the water vapour in the connecting tubes. A measured volume of hydrogen sulphide was introduced from *K* through a spiral which had been freed from air by several alternate exhaustions and fillings with the gas. Nitrous acid solutions were prepared and introduced by mixing in *D* under paraffin oil (Taylor, Wignall, and Cowley, J., 1927, 1923) measured volumes of *N*/2-sodium nitrite and hydrochloric acid solutions, previously freed from air by exhaustion. For nitric oxide reactions, the tap *U* was closed, and the connecting leads and manometer filled with oxygen from *G*, a measured volume of about 140 c.c. being finally introduced into *A*. A measured volume (about 40 c.c.) of nitric oxide was introduced through *C* from *E* through a spiral connexion attached by the double grinding on *C*, and freed from air in the same manner as the hydrogen sulphide connexion. The capillary spiral, *P*, controlling the rate of flow of nitric oxide, was short-circuited by a tap for exhaustion of the leading tube, this tap being closed before gas flow started. The spiral used required ½ hour for the passage of the 40 c.c. of nitric oxide used for a run. The reaction vessel was kept shaken during the admission of the gas.

Tests with measured volumes of nitric oxide in the absence of hydrogen sulphide, dilute alkali solution being used as absorbent, showed that the nitric oxide was practically all converted to nitrous acid under the experimental conditions (see p. 2642). During an actual experiment, the nitrous acid, being continually removed by reaction with hydrogen sulphide, would not attain appreciable concentration. For determination of the nature of the products with appreciable concentrations of nitrous acid, solutions of this substance were run into the same apparatus in the absence of oxygen.

Analysis of Products of Reaction.—(a) *Gases.* Gaseous products were collected through the mercury pump, and the procedure varied according as nitric oxide or hydrogen sulphide was absent: in most of the runs they were not present together. (1) When nitric oxide was absent, nitrous oxide and excess of hydrogen sulphide were condensed in the receiver, *Q*, by liquid air, nitrogen and oxygen being collected at the pump. Nitrogen was estimated by removal of oxygen with phosphorus or pyrogallol. Hydrogen sulphide in *Q* was absorbed by running in alkali solution previously rendered

air-free in *R*, the taps on *MM* being closed until absorption was complete. The nitrous oxide was then collected through the pump, being identified by non-absorption in a small volume of alkaline pyrogallol, the re-kindling of a glowing splint, and combustion with hydrogen. (2) In the experiments with nitrous acid in excess of the hydrogen sulphide, the products were nitric and nitrous oxides. The former was estimated by careful addition of small volumes of pure oxygen over a small volume of alkali solution, the final excess of oxygen being removed by pyrogallol, and the residual nitrous oxide was confirmed by explosion with hydrogen. In the cases described, products remaining in solution could be determined after removal of gaseous products. (3) In reactions with nitrous acid solution and excess of hydrogen sulphide, the gaseous products contained this excess together with nitric and nitrous oxides. Alkali absorption of the hydrogen sulphide was not applicable in this case owing to reaction between the alkali sulphide and nitric oxide, and removal was effected by cupric chloride solution, blank tests having shown that a satisfactory separation was effected (see p. 2642). For solutions with excess of hydrochloric acid, the cupric chloride was added direct to the reaction vessel, a separate run being made for determination of products in solution. For reactions in absence of excess of hydrochloric acid, where residual nitrite was present in solution, the gases were expanded into the exhausted vessel *N* containing cupric chloride solution, the gases remaining after removal of the hydrogen sulphide by shaking being passed to the pump and fresh gas expanded until the reaction vessel was exhausted.

(b) *Dissolved products*. In the reaction solutions, sulphur was determined by collection on a Gooch crucible and drying at 95° (tests having shown that loss during drying did not exceed 0·5 mg.), and sulphur trioxide by barium sulphate precipitation. Sometimes colloidal sulphur passed through the Gooch crucible and was carried down by the barium sulphate; in this case, loss of sulphur by volatilisation was prevented by suspending a beaker of cold water in the mouth of the precipitation beaker, and sulphur and sulphate were determined by drying followed by ignition. Ammonia was determined by distillation into standard acid. In certain cases the nitrogen products collected did not correspond with the quantity of nitric oxide taken. Examination of these solutions (see p. 2637) showed the presence of hydroxylamine, and this was determined by titration with *N*/100-iodine solution in an aliquot portion of the filtrate from the barium sulphate precipitation in experiments where excess of hydrochloric acid was present, the acid solution being boiled again to ensure absence of traces of hydrogen sulphide.

The iodine solution was standardised by means of a standard solution of recrystallised hydroxylamine hydrochloride.

For determination of hydroxylamine and sulphur products in the absence of excess of hydrochloric acid, in which case ammonium nitrite and sulphide were present in the solution, the combined hydrogen sulphide was removed by adding sodium bicarbonate and passing a rapid stream of carbon dioxide for several hours. Sulphur was filtered off, the hydroxylamine determined in a portion of the filtrate, and sulphate in the residue after acidification. Blank tests with known quantities of material showed that this procedure gave satisfactory results.

Tests showed that very nearly one-third of the hydroxylamine was converted into ammonia during alkali distillation for ammonia estimation. This is allowed for in calculating the quantity of ammonia existing in solution.

Small amounts of nitric acid formed were estimated colorimetrically by comparison with a standard sodium nitrate solution, the brucine reaction being used. Nitrite was determined by reduction with Devarda's alloy after distillation of the ammonia, allowance being made for the small amount of nitrate.

Results are shown in Tables I and II, where volumes of gases are reduced to N.T.P., the reactions having been carried out at 30°. In each case reactions were carried out in aqueous solution (the calculated quantity of hydrochloric acid being added to the sodium nitrite when nitrous acid solutions were being prepared), and repeated with a solution of $N/20$-hydrochloric acid in the reaction vessel. The columns headed "S as SO_3" show the actual quantities of sulphur present as trioxide. In Table II, for comparison with Table I the quantities of nitric oxide that would produce the nitrous acid used if entirely converted into it are shown. On account of the less extensive reduction, it was necessary to take larger amounts of nitrous acid than correspond to the 40 c.c. of nitric oxide of Table I, but the yields have been calculated to 40 c.c. and are shown together with the actual amounts of reacting substances. In Expts. 13—16, where an excess of nitrous acid was taken, the amount consumed by reaction was calculated from the amounts of nitrogen products. If the amount of sulphur products equivalent to the nitrogen products other than nitric oxide is calculated, the residual sulphur corresponds fairly closely with the amount of nitric oxide recovered, showing that very little has been produced by direct decomposition of nitrous acid. Table I contains results for reactions with considerable hydrogen sulphide and very little nitrous acid; the opposite condition of excess of nitrous acid in quantity and low hydrogen sulphide concentration is shown in Table II

* In Expts. 21 and 22 the quantities of product are for the equivalent of 40 c.c. of nitric oxide exclusive of that remaining as nitrite, the approximate amounts of which were equivalent to 4 c.c. of NO in each case.

† In Expt. 21, nitric acid was produced equivalent to 0·1 c.c. of NO.

(Expts. 13—16), where the hydrogen sulphide was admitted over the water in the reaction vessel and the nitrous acid solution run in beneath the water, reaction being completed by subsequent shaking with consequent solution and oxidation of the hydrogen sulphide. Expts. 17—22 of Table II represent an intermediate condition, the hydrogen sulphide being in excess but the nitrous acid being present in quantity. In this case, the water in the reaction vessel was nearly saturated with hydrogen sulphide by admitting gas and shaking until the pressure was nearly atmospheric before addition of the nitrous acid.

For the identification of hydroxylamine, the material was prepared in greater quantity by passing rapid streams of oxygen and hydrogen sulphide and a slow stream of nitric oxide through several hundred c.c. of *N*/5-hydrochloric acid solution in a bottle carried on a shaker. After several hours, when the solution had become nearly neutral, the sulphur was filtered off, and the solution evaporated to dryness with sufficient barium chloride to precipitate all the sulphuric acid. The residue was extracted with absolute alcohol, the extract evaporated, the crude residue extracted with alcohol–ether, and the solvent again removed. The resulting white solid reduced iodine solution and Fehling solution (Found: Cl, by $AgNO_3$ titration, 52·4. Calc. for NH_2OH,HCl, 51·1; for NH_4Cl, 66·4%); 0·014 g. required 58 c.c. of iodine solution, 29 c.c. of which were equivalent to 10 c.c. of *M*/100-hydroxylamine solution (Calc. for NH_2OH,HCl, 58·4 c.c.).

Discussion.

Considering first the nitrogen products, it will be seen from Table II that when the nitrous acid is in excess and the hydrogen sulphide concentration relatively small (Expts. 13—16) very small amounts of hydrogenated nitrogen compounds are formed (the very small quantities of ammonia were determined by Nessler solution), nitric oxide and smaller amounts of nitrous oxide being the principal reduction products. When the hydrogen sulphide is in excess, however, and the nitrous acid concentration is very small (Table I) the reduction is almost entirely to hydrogenated products, ammonia and hydroxylamine in acid solution, and chiefly ammonia with a smaller proportion of hydroxylamine in aqueous solution.

In the presence of excess of oxygen, nitric oxide would be reconverted into nitrous acid, and a catalytic effect would be apparent from a greater quantity of sulphur products and greater oxygen consumption; but it can be shown from Expts. 1—4, 8, and 9 that there has been no such catalytic effect. In the tables, the quantities of sulphur found as trioxide have been multiplied by 4 to give the quantity of free sulphur that would have been produced by a corre-

sponding amount of oxidation, and the equivalent quantity of free sulphur added to the actually determined free sulphur is given in the column "Equivalent S." The column "Calculated S" shows the amount of sulphur corresponding to the oxidation equivalent of the various nitrogen products collected. As the calculated and the equivalent sulphur correspond, reduction to the nitrogen products found must have been direct without intervening formation of nitric oxide. The quantities of oxygen consumed in Expts. 1—4 are also very close to the 10 c.c. required for direct formation of nitrous acid from 40 c.c. of nitric oxide, further re-formation of which would consume more oxygen. The greater quantity of oxygen consumed in Expts. 6 and 7 is discussed later.

The most noteworthy product is the hydroxylamine, which is destroyed by reaction with nitrous acid. Its formation and stability during reduction of very dilute nitrous acid solution are probably due to the fact that each molecule of the acid is reduced by the excess of hydrogen sulphide before it has opportunity to react with hydroxylamine. The production of the compound by Divers (*loc. cit.*) may be similarly explained, for the effect of hydrogen sulphide on a slightly soluble salt in suspension would be to produce a small concentration of nitrous acid which would be continually removed by the hydrogen sulphide.

When the addition of nitric oxide is effected in the absence of hydrochloric acid, there is still only a very small yield of gaseous products, but ammonia is the principal reduction product, the quantity of hydroxylamine being smaller than in acid solution; but, as shown in Expts. 5—7, a proportion of the nitrous acid has formed ammonium nitrite which has not had time to react with the hydrogen sulphide—it will be shown later that this reaction is very slow (p. 2639).

The result of acidifying the solutions containing nitrite is shown in Expts. 10—12 (Table I), where hydrochloric acid was added after addition of nitric oxide. The calculated quantity of sulphur is smaller than the sulphur found, whilst the oxygen consumption is greater than in Expts. 6 and 7, where no acid was added after reaction. Evidently, the nitrous acid set free on addition of hydrochloric acid had sufficient concentration to form some nitric oxide and thus, to a small extent, to act catalytically. The relatively considerable amounts of nitrogen and nitrous oxide must also have been produced during the reaction after acidification, very little being obtained in Expts. 5—7.

Considering next the sulphur products, it will be seen that, except in the case where nitrous acid is present in quantity and in excess, the hydrogen sulphide concentration being small (Expts. 13—16),

the greater proportion of the hydrogen sulphide is oxidised to sulphur with a relatively small amount of sulphur trioxide. Expts. 17—22 show that, even when nitrous acid solution of appreciable concentration is added to a fairly concentrated hydrogen sulphide solution, the sulphur predominates.

In the hope of obtaining further information as to the nature of the processes involved, the reaction between hydrogen sulphide and ammonium nitrite was investigated. In Table IIIA is shown the result of passing hydrogen sulphide continuously through an approximately $N/20$-solution of ammonium nitrite (prepared from silver nitrite and ammonium chloride). There was gradual reduction of nitrite, chiefly, but not completely, to ammonia, about 50% being reduced in 24 hours. The sulphur produced was partly precipitated and partly dissolved as yellow polysulphide. The slow reaction when compared with the extremely rapid oxidation with free nitrous acid suggests that the free acid produced in the present case by hydrolysis is the active agent, and not the nitrite ion which is now present in quantity. The solutions saturated with hydrogen sulphide had a very feebly acid reaction, which diminished as the ammonium sulphide increased; p_H values determined by a comparator with phenol-red are shown. In order to study the effect of sulphide-ion concentration, the experiment was repeated with addition of sufficient ammonium sulphide to make the solution $N/6$ with regard to ammonia. The result of passing a continuous stream of hydrogen sulphide through this mixture is shown in Table IIIB. The reaction, at first slower than in the absence of excess of sulphide, accelerated considerably after a few hours. The sulphur produced dissolved, forming a yellow polysulphide solution.

Table IIIc shows the result of adding ammonium sulphide and sulphur, forming polysulphide, at the commencement of reaction. It will be seen that the reaction is rapid from the beginning. The results shown in Table III are plotted in Fig. 2.

N/6-Ammonium sulphide solution saturated with hydrogen sulphide has a slightly alkaline reaction, p_H 7·2—7·3 by comparator,

FIG. 2.

A = *Nitrite.* B = *Nitrite + sulphide.* C = *Nitrite + polysulphide.*

Hydrogen sulphide and ammonium nitrite.

and the polysulphide solution has a value of the same order. The very slow reaction with considerable ammonium hydrosulphide in solution is probably due to diminished nitrous acid concentration owing to smaller hydrogen-ion concentration. The increased rate when sulphur is formed or added in sufficient quantity may be ascribed to the influence of polysulphide ion. Although Küster (*Z. anorg. Chem.*, 1905, **44**, 431) has shown by *E.M.F.* measurements that these ions have a smaller reduction tendency than the sulphide

ion, he has also found (*ibid.*, **43**, 53) that, as the proportion of sulphur increases, the hydrolysis of sodium polysulphide diminishes, thus indicating greater strength for the acid. In the solutions now under consideration, which were saturated with hydrogen sulphide, the principal constituents would be NH_4HS and NH_4HS_x, and the principal ions $NH_4^{\cdot}$ and HS' in one case, and $NH_4^{\cdot}$ and HS_x' in the other. The polysulphide will be less hydrolysed and more dissociated, and the HS_x' ion will be present in greater quantity than the HS' ion in the absence of sulphur; thus a considerable increase in concentration of the reducing ion will be caused by the presence of sulphur dissolved as polysulphide. This in turn may lead to more rapid reaction.

The last experiments thus afford some evidence that the reaction between hydrogen sulphide and nitrous acid is between the undissociated acid and the sulphide ion. It may be suggested that the primary reactions are of simple type, and that nitric and nitrous oxides and nitrogen are secondary products. With appreciable concentration of nitrous acid, the reactions

$$(1)\ 3HNO_2 + S'' \longrightarrow 3HNO + SO_3(+ 3H_2O)$$

and

$$(2)\ HNO_2 + S'' \longrightarrow HNO + S\ (+ H_2O)$$

may be expected. The proportions in which reactions (1) and (2) occur would largely depend on the relative concentrations of the reacting substances. Reaction of the hyponitrous acid with more nitrous acid would yield nitric oxide. Direct decomposition of hyponitrous acid has been shown to yield nitrous oxide and nitrogen (Divers, J., 1889, **55**, 112). The nitric oxide and some of the nitrogen and nitrous oxide found in various experiments may thus be accounted for, a portion of the nitrous oxide and nitrogen probably being formed as secondary products of reaction (3) (below). With smaller concentration of nitrous acid and considerable hydrogen sulphide concentration, reactions

$$(3)\ HNO_2 + 2S'' \longrightarrow NH_2OH + (H_2O) + 2S$$

and

$$(4)\ HNO_2 + 3S'' \longrightarrow NH_3 + (2H_2O) + 3S$$

may be expected, with the possibility of more nitrous oxide and perhaps nitrogen being formed by reaction between nitrous acid and hydroxylamine.

In the present work the slow addition of nitric oxide to the system would produce an exceedingly small concentration of nitrous acid which would not increase, owing to reaction with hydrogen sulphide, and secondary reactions with nitrous acid would not be expected to occur to any extent. Reactions (3) and (4) appear to have proceeded together in Expts. 1—4 in the presence of excess of

hydrochloric acid, whilst in absence of acid (Expts. 5—9) reaction (4) predominates. Two causes may be suggested to account for this variation: (1) A reduced free nitrous acid concentration owing to nitrite formation and reduction of hydrogen ion through the presence of hydrolysed ammonium sulphide—it does not seem likely, however, that variation in an already very small concentration of a substance taking a unimolecular part in a reaction would appreciably alter the nature of the reaction in the presence of considerable excess of the second reactant. (2) Variation of sulphide-ion concentration is probably of greater importance; this concentration, very small in hydrochloric acid solution, will be much greater in presence of ammonium sulphide, thus favouring reaction (4).

In Table II there is no definite difference between the products in Expts. 15 and 16 with only nitrous acid, and those in Expts. 13 and 14 with excess of hydrochloric acid. This is to be expected on account of the considerable amount of sulphuric acid produced. Small variations between products in Expts. 17—20 and Expts. 21 and 22 with excess of hydrogen sulphide may be due to variation in acidity, as only small amounts of sulphuric acid were produced. Considerable variation is not to be expected, as the solutions would in all cases remain acid until most of the nitrous acid was destroyed.

A blank test with hydrogen sulphide, oxygen, and an amount of ammonia equal to that present as sulphide at the end of reaction, yielded in the absence of nitric oxide about 4 mg. of free sulphur and 0·3 mg. as trioxide in ½ hour. As the average ammonia concentration during a run would be much less than the maximum, the amount of sulphur formed by direct oxidation in Expts. 10—12 would be very small. The greater oxygen consumption in Expts. 6 and 7 than in Expts. 1—4 may be due to this small direct oxidation.

The following are results of some other blank tests.

(1) Absorption by copper chloride of hydrogen sulphide from mixture with nitric oxide:

100 c.c. of H_2S + 38 c.c. of NO taken; 37·5 c.c. of NO recovered.

(2) Absorption by alkali solution of nitric oxide (41 c.c.) from mixture with oxygen (10 c.c.):

$KMnO_4$: required 36·9 c.c.; calculated 36·7 c.c.

(3) Estimation of nitrite in ammonium nitrite solution containing polysulphide: 25 C.c. of N/20-ammonium nitrite solution were added to concentrated alkali and the ammonia was distilled off. The nitrite was then reduced by Devarda's alloy and the resulting ammonia required 12·0 c.c. of N/10-HCl. The process was then repeated with a fresh sample containing the amount of polysulphide used in the experiments of Table IIIc, and 11·9 c.c. of acid were

required. There has evidently been no appreciable reduction of nitrite in the strongly alkaline solution during the time required for preliminary distillation of the ammonia.

(4) In view of the fact that hydroxylamine is known to act as an oxidising agent under certain conditions, the possibility of its reacting with hydrogen sulphide in presence of ammonium sulphide and sulphur was tested under various conditions. It was found that no measurable loss of hydroxylamine occurred in dilute solutions in an hour.

Summary.

The products of reaction of nitrous acid solution with hydrogen sulphide vary with relative concentrations. With appreciable concentration of nitrous acid, the reduction products are chiefly nitric and nitrous oxides; with small concentrations of nitrous acid, they are ammonia and hydroxylamine, the proportions of which vary according to the concentration of sulphide ion in solution.

A series of simple reactions is proposed, nitric and nitrous oxides being regarded as products of hyponitrous acid formed primarily.

The proportion of sulphur trioxide to free sulphur is small even with fairly concentrated nitrous acid solutions unless the hydrogen sulphide concentration is small.

Hydrogen sulphide reacts slowly with ammonium nitrite, converting it into ammonia. The rate of reaction is diminished by addition of ammonium sulphide and increased by addition of polysulphide. A suggested explanation is based on the fact that the polysulphide ion is known to be more acidic than the sulphide ion and would thus furnish a greater concentration of reducing ions in solution.

THE UNIVERSITY OF QUEENSLAND,
BRISBANE.

[*Received, July 18th*, 1928.]

CCCXLVII.—*The Velocity of the Acid Hydrolysis of Cotton Cellulose by Hydrochloric Acid, Alone, and in Presence of Alkali Chloride.*

By EDWARD HUNTER.

IT has been shown by Åkerlöf (*Z. physikal. Chem.*, 1921, **98**, 260) that the velocity of hydrolysis of ethyl acetate by hydrochloric acid in presence of large concentrations of neutral salt is a function of the activity of the hydrogen ion, irrespective of the kation of the added chloride.

The work here described was undertaken to determine whether

the principles of activity could be extended to a heterogeneous reaction catalysed by hydrogen ions. The reaction chosen is the hydrolysis or "modification" of cotton cellulose in hydrochloric acid both alone and in presence of potassium, sodium, and lithium chlorides. With dilute acid the ultimate reaction product is hydrocellulose, a solid adhering to the unchanged cotton. According to Wohl and Blumrich (*Z. angew. Chem.*, 1921, **34**, 17), this substance is a reversion product of dissolved reducing sugars (primary products of reaction) and some undissolved substance in the solid cotton. They observe that hydrocellulose is much more difficult to hydrolyse than cellulose, but it should be borne in mind that hydrolysis can be effected by prolonged heating with very concentrated acid.

EXPERIMENTAL.

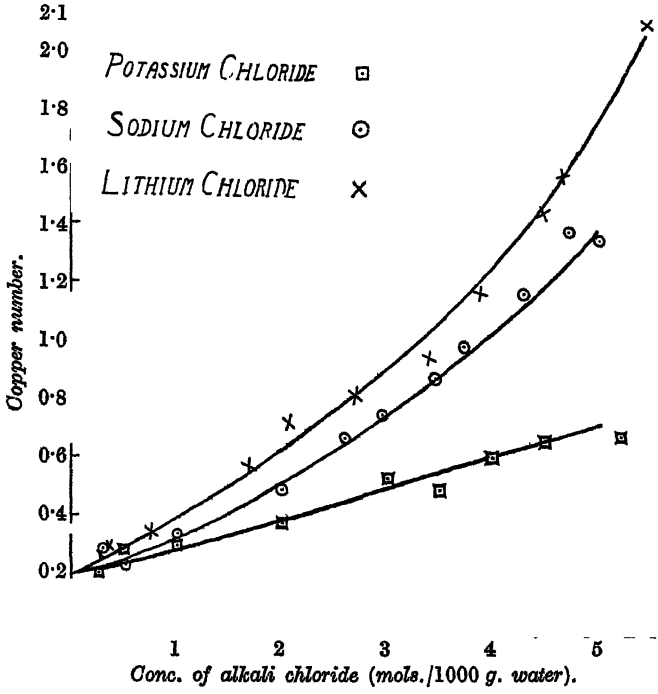
Methods of Hydrolysis and Analysis.—The hydrolyses were carried out by adding 70 c.c. of the acid solution to a weighed quantity of cotton (about 2·7 g.), stirring to remove air bubbles, and immersing the reaction vessel in the thermostat. For potassium chloride and some lower concentrations of sodium chloride the vessel was a tightly-corked flask, but it was found advisable to carry out the other reactions in sealed glass tubes.

After hydrolysis the cotton was washed by water with suction, and its copper number determined by Brady's method (see also Clibbens and Geake, *Shirley Institute Memoirs*, 1924, **2**, 387). Two corrections were applied in the calculation. (1) The moisture content of the original cotton was determined by heating 1 g. samples, loosely packed in weighing bottles, at 105° to constant weight. (2) The copper number of unmodified cotton (mean of several determinations) was subtracted from the value found after hydrolysis.

When a sample of cotton was steeped in acid, the concentration of acid slowly decreased by a slight amount until an equilibrium was reached after about 2½ days :

Time (hrs.)	0	4·75	27	64·3
Acid concentration, *N*	0·100	0·0992	0·0983	0·0980

The fall in concentration in 60 hrs. of several concentrations of acid was measured :



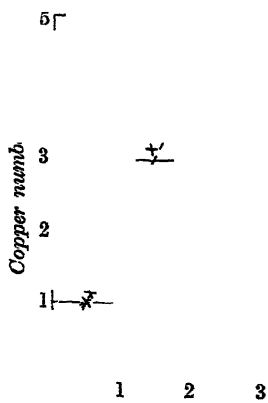
Original concentration	0·869	0·435	0·244	0·0871
Final concentration	0·866	0·433	0·242	0·0855
Fall, %	0·35	0·46	0·8	1·8

This change in concentration is ascribed to imbibition of acid by the cotton, and it has been ignored in the velocity measurements.

For the velocity of the hydrolysis (by acid of constant concen-

tration), Birtwell, Clibbens, and Geake (*J. Textile Inst.*, 1926, **17**, T161) have submitted the formula $N_{Cu} = KT^{0.6}$, where N_{Cu} is the copper number, K a velocity coefficient, and T the time of reaction in days. The results of these authors show that K is only constant within 5—10%. Furthermore, the index here given as 0·6 apparently varies with the type of cotton. For these reasons, in the present work, reaction velocities are compared by carrying out the acid steeping for exactly the same length of time in all cases, a period of 3 days at 40° being chosen as most suitable.

FIG. 1.

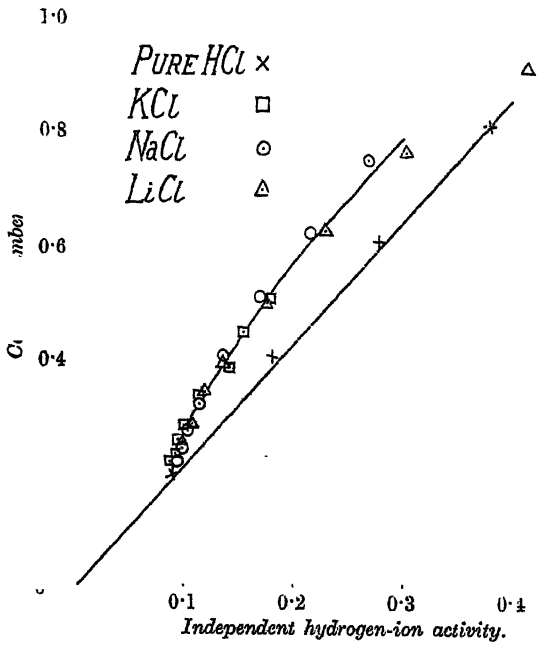


N/10-Acid (0·1 mol. per 1000 g. of water) was prepared by dilution of standard hydrochloric acid made by the method of Hulett and Bonner (*J. Amer. Chem. Soc.*, 1909, **31**, 390). The acid–alkali chloride mixtures were prepared by adding weighed amounts of salt to a known weight of acid. In the lithium chloride series the concentrations of acid and chloride were checked by analysis.

Results.—In Fig. 1 the copper numbers for the 3-day hydrolysis at 40° are plotted against the concentrations (x) of neutral salt in the mixture 0·1HCl + xRCl + 1000 g. H_2O; and Fig. 2 shows the results for pure acid of varying molality.

The last three results in the acid series do not represent the true velocity values for the corresponding molalities of acid. Two reasons can be given for this. (1) Hydrolysis with such strong acid for 3 days resulted in a complete change of form of the cotton to short thread-like particles, in place of the interwoven fibres left after more moderate modification; hence it seems likely that the hydrocellulose itself was partly decomposed by the acid. (2) In determining the copper number of such highly modified cotton samples, the amount of copper solution used in the standard method was insufficient, and it was therefore necessary to use a larger quantity, thereby deviating from the rigid conditions prescribed for the method.

FIG. 2.



It is obvious from the diagrams that no great quantitative accuracy can be claimed for the velocity measurements. The source of the largest error is almost certainly in the process of hydrolysis, for two samples of cotton of equal weight cannot be expected to offer the same surface area to the solution. However, the results clearly show the qualitative effects upon the reaction velocity of adding alkali chloride to $N/10$-hydrochloric acid.

The curves of Fig. 1 resemble those connecting molality of added chloride with hydrogen-ion activity in solutions of the type used. This suggests a connexion between hydrolysis velocity and the hydrogen-ion activity of the acid solutions. The curves in Fig. 3 have been obtained by plotting Harned's values for hydrogen-ion activity in solutions of this type (*J. Amer. Chem. Soc.*, 1920, **42**, 1808) against the copper numbers for corresponding molalities, as read off from Figs. 1 and 2. Harned's data refer to 25°, but only a small error is introduced by applying them to 40°.

It will be seen from the diagram that in pure acid there is a simple direct proportionality between hydrogen-ion activity and copper number (velocity of reaction) for activities of the same order as those of the acid–alkali chloride series. No such simple relation exists for the acid–salt mixtures. Plotted separately, the results for each series give a smooth curve. The three curves are practically coincident near their origin, and are only slightly divergent

with increasing molality. In Fig. 3 a single curve has been drawn for the three series; this originates on the pure acid curve at the hydrogen-ion activity of $N/10$-acid, and then rises above it. Since Harned's values are limited to solutions which are not stronger than $3M$ with respect to added chloride, the ultimate trend of the activity–velocity curves has to be left undefined—they may either become parallel to the pure acid line or intersect it at very high values of the hydrogen-ion activity.

FIG. 3.

For the range examined, the notable fact is that, of two solutions having the same hydrogen-ion activity, that with neutral salt present gives a higher reaction velocity than that with acid alone. In attempting an explanation of this fact, it seems natural to assume that reaction occurs between dissolved reactants in a thin layer of solution touching the surface of the solid cotton; in these circumstances Brönsted's equation (*Z. physikal. Chem.*, 1925, **115**, 337) can be expected to hold, *viz.*, $v = ka_Aa_B/f_X$, where v is the velocity, k a velocity coefficient, a_A and a_B are the activities of the reactants, and f_X is the activity coefficient of the "critical complex." If the reaction be written as $H^{\cdot},H_2O$ + Cellulose $\longrightarrow$ [(Cellulose),$H^{\cdot},H_2O$]$^{\cdot}$ $\longrightarrow$ Hydrocellulose + $H^{\cdot}$, one obtains the expression $v = ka_Ba_C/f_X$,

a_H and a_C being the respective activities of the hydrogen ion and the neutral cellulose, and f_x having its former significance. Since the cellulose is a neutral molecule, the expression can be modified to $v = ka_Hc/f_x$, where c is the concentration of cellulose. Apart from the independent hydrogen-ion activity, the important variant in this expression is f_x, for the critical complex is a charged molecule, the activity coefficient of which may be expected to be very responsive to changes in the activities of the other reactants. Now, for similar hydrogen-ion activity, the saline solutions have a far greater molality of electrolyte than the salt-free solutions. In Fig. 3 the highest molality of pure acid is 0·5, whilst that of the acid–chloride solutions reaches 3·1. Hence any effect upon the activity coefficient of the "critical complex" with increasing molality of electrolyte will be shown to a more pronounced degree in the latter type of solution. The relative form of the activity–velocity curve for such solutions and for salt-free solutions is explained if it is accepted that addition of large quantities of electrolyte to the solution lowers f_x, for the velocity of the reaction is inversely proportional to this activity coefficient. The gradual divergence of the activity–velocity curves for the three different chlorides can then be ascribed to slight differences in the quantitative effects of each salt on the "critical complex."

The author's thanks are due to Professor A. J. Allmand, under whose direction the work was carried out, and to Dr. D. A. Clibbens, who supplied the cotton and gave very helpful advice.

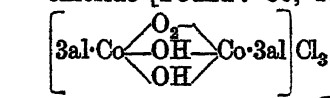
UNIVERSITY OF LONDON,
KING'S COLLEGE. [*Received, May 23rd*, 1928.]

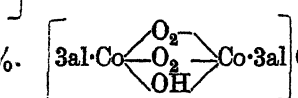
CCCXLVIII.—*Cobalt Allylamines: A Supposed Co-ordination Number of Eight for Cobalt.*

By WILLIAM RALPH BUCKNALL and WILLIAM WARDLAW.

FROM a careful survey of the chemical evidence, Sidgwick ("The Electronic Theory of Valency," p. 152) has concluded that up to the end of the first long period in the classification of the elements the highest covalency of an atom is six. He also states (*op. cit.*, p. 160) that "it should be noted that there are a certain number of compounds which appear to indicate values of the covalency in excess of those allowed by the rule. In none of these have the structure and molecular weight been definitely ascertained." There are recorded in the literature, however, the preparation and

properties of an interesting complex salt of cobalt, which is mentioned by Weinland ("Komplexverbindungen," 1919, p. 13) as an example of a co-ordination number of eight for cobalt, instead of the usual six anticipated from Sidgwick's rule. The substance in question was prepared by Pieroni and Pinotti (*Gazzetta*, 1915, **45**, ii, 100), who found that when dry air was drawn through a saturated solution of cobaltous chloride (dried at 140°) in absolute alcohol to which dry allylamine had been added there separated a red, crystalline compound. It dissolved in cold water with the production of a neutral solution, and from cryoscopic molecular-weight determinations it was concluded that in aqueous solution the substance dissociated into a maximum of four ions. From these data and the percentages of cobalt and chlorine found in the compound, Pieroni and Pinotti assigned to the new substance the formula $[Co,8C_3H_5\cdot NH_2]Cl_3$. Later, however, Pieroni (*ibid.*, 1921, **51**, i, 42) reinvestigated the reaction and, as a result of a more complete analysis, deduced the new formula





$$\left[Co\begin{matrix}6C_3H_5\cdot NH_2\\2O_2\end{matrix}\right]Cl_3,H_2O_2.$$

On titration with permanganate, the titre was in excess of that demanded by the unsaturated amine, and it was suggested that the excess was required by the hydrogen peroxide present in the molecule. As both formulæ assign a co-ordination number of eight to the cobalt and the reaction appeared to have several unusual features, it seemed of interest to reopen the investigation.

Experimental.

*Preparation of Hexa-allylamineperoxodihydroxodicobalt Trichloride,** $\left[3al\cdot Co\begin{matrix}O_2\\OH\\OH\end{matrix}Co\cdot 3al\right]Cl_3$.—To a saturated solution of cobaltous chloride (10 g.; dried at 140°) in 100 c.c. of water-free alcohol, dry allylamine (32 g.) was added in portions, with constant shaking, air being displaced by a current of nitrogen; considerable heat was evolved and the solution became reddish-blue. On cooling, purplish-red, needle-like crystals separated in good yield. They were very deliquescent and unstable, allylamine being readily liberated. With alcohol, the crystals gave a blue solution, and in water they underwent decomposition, cobalt hydroxide being precipitated almost immediately. Pieroni assigned to these crystals the composition $CoCl_2,3C_3H_5\cdot NH_2$. When a current of dry air was passed through the reaction flask containing the crystals in contact with their mother-liquor, the

solution changed in colour from purplish-red to brownish-red, and minute red crystals slowly separated. After oxidation for about 3 days, these crystals were collected, washed with absolute alcohol (in which they are insoluble) until the filtrate was colourless, and then air-dried on a porous plate. In the first attempts to obtain this oxidised product, cobalt hydroxide separated after the oxidation had proceeded for a short time. This was apparently due to the presence of moisture in the alcohol, for this difficulty did not arise when the solvent had been refluxed and distilled twice over barium oxide and twice over calcium turnings before use. The allylamine for the early experiments was prepared by the method of Pieroni and Pinotti (*Gazzetta*, 1915, **45**, i, 100), but later, purchased samples were dried by two distillations over sodium and then had b. p. 55°.

Analysis.—The cobalt was estimated as sulphate by gentle ignition of the substance with sulphuric and nitric acids in an air-oven. For the estimation of the chlorine, cobalt was removed as hydroxide by addition of sodium hydroxide to a solution of the substance, and the chloride then precipitated as silver chloride [Found: Co, 18·6; Cl, 16·7; C, 33·6; H, 6·7; N, 13·1.  (I) requires Co, 18·65; Cl, 16·8; C, 34·1; H, 7·0; N, 13·3%.  (II) requires Co, 18·2; Cl, 16·45; C, 33·4; H, 6·7; N, 12·9%]. From the analytical results, formula (I) seems the more probable.

Molecular-weight Determinations.—The molecular weight was determined by the depression of the freezing point of water. If either of the above-mentioned formulæ represents the correct formulation, then four ions should be present in solution and the apparent molecular weight, when ionisation is complete, should be *ca.* 160. The results in Table I, calculated for formula (I), furnish evidence in favour of such a formulation.

TABLE I.

G. of substance per 100 g. water.	Conc. (mols. per 1000 g. water).	Osmotic factor.	Apparent mol. wt.
1·022	0·01616	3·60	176·0
1·159	0·01833	3·46	182·7
1·736	0·02744	3·11	203·0

Molecular-conductivity Determinations.—The molecular conductivity was determined at various dilutions at 0°. Table II gives the values of μ for the complex chloride, and for comparison the

values of the molecular conductivities of typical salts at 0° are given in Table III.

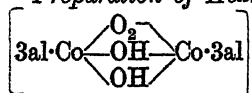


TABLE II.

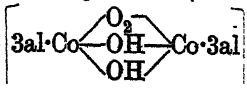

v (litres/mol.)	45·6	65·9	131·8	263·6	527·2	730·0
μ	119	128·8	144·3	159·3	176·3	184·8

TABLE III.

v (litres/mol.)	32	64	128	256	512	1024	
$K_3Fe(CN)_6$	215	227	243	254	264	282	
$K_3W(CN)_8$	211	224	238	250	259	264	
$AlCl_3$						226	(approx.)
K_2SO_4					158	161	

From the results given in Table II, μ_∞ for the complex chloride is estimated to be *ca.* 210. Although the values of μ for the complex salt are less than would be expected for a normal four-ion compound, they are nevertheless in accord with the formula if we assume that the large complex ion is slow-moving, as is frequently the case. Since λ_∞ for Cl′ at 0° is *ca.* 46, then by Kohlrausch's law the ionic mobility of the complex ion is approximately 70, the usual figure for a tervalent ion being about 110.

Preparation of Hexa-allylamineperoxodihydroxodicobalt Trinitrate,  $(NO_3)_3$.—Pieroni and Pinotti noticed (*loc. cit.*) that the addition of nitric acid to a concentrated aqueous solution of the complex chloride produced red, acicular crystals, which were not further investigated. It has been found, however, that the addition of either nitric acid or a solution of any metallic nitrate will cause precipitation of a red compound. This new substance thus appears to be the result of an ionic reaction between the complex chloride and the nitrate ion.

The compound was prepared by the addition of about 1 c.c. of pure nitric acid to 20 c.c. of a solution of the complex chloride (2 g.), and was freed from acid by washing with cold water, in which it is slightly soluble; the filtered substance was air-dried on a porous plate. It contained no chlorine, and when it was moistened with sulphuric acid, nitric acid was liberated. It was slightly soluble in cold water, and on standing or by warming, hydrolysis occurred with the precipitation of hydroxide. Warming with sodium hydroxide caused the evolution of allylamine, and by distillation with sodium hydroxide and Devarda's alloy the nitrate groups were reduced to ammonia, which was titrated together with the liberated allylamine (Found: Co, 16·6; N, 17·8; N : Co = 9·03 : 2.  $(NO_3)_3$ requires Co, 16·6; N, 17·7%).

The nitrate hydrolyses in boiling water, but the presence of nitric acid prevents decomposition. Pieroni and Pinotti (*loc. cit.*) remarked on the formation of a yellow substance together with a heavy red compound when the complex nitrate was boiled with dilute nitric acid. It has been found, however, that the only product of this reaction is a red precipitate of the same composition as the above nitrate. It appears that the presence of the nitric acid merely retards the hydrolysis, and possibly decreases the solubility of the complex nitrate. If the concentration of the nitric acid is too high, the salt is dissolved and the complex ion is apparently destroyed.

Reactions of the Complex Salts.—Concentrated hydrochloric acid gives, with either of the complex salts, a dark green, insoluble substance, which on warming dissolves to a bluish-green solution of cobaltous chloride and allylamine hydrochloride. The addition of concentrated hydrochloric acid to an aqueous solution of the complex chloride produces a green solution which reverts to the blue colour of cobaltous chloride only on warming. Sulphuric acid decomposes the complex ion and forms cobaltous sulphate. With silver nitrate solution, the complex chloride gives an immediate precipitate of silver chloride, together with a red precipitate, in concentrated solutions, of the complex nitrate. Ammonium sulphide immediately precipitates the cobalt as sulphide. The complex salts react, on warming, with potassium iodide solution with the liberation of iodine; with potassium bromide, however, no oxidation could be detected.

Discussion of Results.

The most important result of this investigation has been to indicate a new formulation for the salts originally prepared by Pieroni and Pinotti. The analytical data now obtained are compared below with those previously recorded for the complex chloride:

	Co.	Cl.	N.	C.	H.
Pieroni and Pinotti	9·7	17·4			
Pieroni	10·0; 9·25	17·1	13·7	35·76	7·76
Present authors	18·6	16·7	13·1	33·57	6·71

Our percentages for Cl, N, C, and H are of the same order as those determined by Pieroni and Pinotti for this compound, but there is a marked difference in the percentages of cobalt. Whereas the analytical figures of Pieroni and Pinotti indicate a ratio of Co : Cl = 1 : 3, the new figures show a ratio of 2 : 2·982. Such a ratio would be anticipated from the results obtained by Werner from the oxidation of ammoniacal solutions of cobaltous salts. He was

able to isolate and examine many new substances which he formulated as bridge compounds ("Neuere Anschauungen auf dem Gebiete der Anorganischen Chemie," 1920 ed., pp. 293 *et seq.*); for example, one of the first products of the atmospheric oxidation of ammoniacal cobalt solutions is a brownish-black oxy-compound of the composition $[(NH_3)_5Co^{III}\cdot O_2\cdot Co^{III}(NH_3)_5]X_4$, which on further oxidation yields the intensely dark green, so-called anhydro-oxy-cobaltate, $[(NH_3)_5Co^{III}\cdot O_2\cdot Co^{IV}(NH_3)_5]X_5$. Other products obtained by similar means include $\left[(NH_3)_4Co^{III}\begin{matrix}OH\\OH\end{matrix}Co^{III}(NH_3)_4\right]X_4$, the melano-chloride $\left[\begin{matrix}(NH_3)_3\\Cl_2\end{matrix}Co^{III}\cdot NH_2\cdot Co^{III}\begin{matrix}(NH_3)_3\\Cl_2\end{matrix}\right]X$, and also the three-bridge compound, $\left[(NH_3)_3Co^{III}\begin{matrix}NH_2\\O_2\\OH\end{matrix}Co^{IV}(NH_3)_3\right]X_3$. From the melano-chloride by simple reactions the compound

$$\left[(NH_3)_3Co^{III}\begin{matrix}NH_2\\OH\\OH\end{matrix}Co^{III}(NH_3)_3\right]X_3$$

can be prepared.

The possibility that the compounds $\left[3al\cdot Co\begin{matrix}O_2\\OH\\OH\end{matrix}Co\cdot 3al\right]X_3$ would result from the reactions dealt with in the present investigation is therefore not unexpected. The reaction is in accordance with the general tendency of alkaline solutions of cobaltous salts to produce polynuclear complex compounds on atmospheric oxidation. The new formulation assigns to cobalt valencies of three and four. Although quadrivalent cobalt is not normally considered to exist, yet Werner found it necessary to postulate its presence in such polynuclear compounds as those mentioned above. Moreover, it will be noticed that this formula assigns to cobalt the normal covalency of six, and there is no evidence that Pieroni and Pinotti's compounds necessitate any modification of Sidgwick's rule.

It is interesting to compare the results obtained from nickel salts under similar conditions. Pieroni and Pinotti (*Gazzetta*, 1914, **44**, ii, 366) found that by the action of allylamine on various nickel salts, several substances could be prepared which, like the compound of cobaltous chloride with allylamine, were very unstable, hydrolysing immediately in water. They concluded that in no case was there evidence of the existence of complex ions.

This investigation is being extended to a study of the products of the atmospheric oxidation of alcoholic solutions of cobalt salts in the presence of various other amines.

The authors wish to express their grateful thanks to the Department of Scientific and Industrial Research for the award of a research grant to one of them (W. R. B.), and to the Chemical Society for a grant in aid of this investigation.

UNIVERSITY OF BIRMINGHAM,
EDGBASTON. [*Received, June 9th*, 1928.]

CCCXLIX.—*The Density of Boric Oxide Glass and the Atomic Weight of Boron.*

By ARNOLD COUSEN and WILLIAM ERNEST STEPHEN TURNER.

IN an important paper on this subject, Briscoe, Robinson, and Stephenson (J., 1926, 70) were concerned, not with the absolute atomic weight of boron, but with the relative values for the element present in boron minerals obtained from various terrestrial sources, and in the discussion of the results they were inclined to think that the maintenance by them of the same conditions of preparation of the boric oxide glass samples would ensure a valid comparison of density values even supposing some slight error might be present in the absolute values due to the inclusion of minute traces of moisture.

Of the six preparations of boric oxide, obtained from different sources, the densities ranged between 1·79711 (at 17·36°) and 1·79404 (at 19·25°), corresponding to extreme variations in calculated atomic weights for boron of 10·847 and 10·788. These differences in densities are substantial, being no less than three units in the third place of decimals. Differences in the temperature of determination in no way account for them: as the authors themselves indicate, a temperature change of 0·1° should only modify the density by one unit in the eighth decimal place. Consequently, the authors were led, in conjunction with certain other evidence, to conclude "that boron, like lead, has an atomic weight varying with its source."

In reopening this subject for discussion, we have no observations to make on the evidence previously obtained by Briscoe and Robinson (J., 1925, **127**, 696) on the basis of their determination of the ratio BCl_3 : Ag, but we are concerned with the density determinations on boric oxide glass and with their interpretation; for when reading the paper of Briscoe, Robinson, and Stephenson on its publication, doubt immediately occurred to one of us of the adequacy of the tests for strain in the beads of fused boric oxide. The authors stated: "A number of test beads examined . . . between crossed Nicols, appeared free from strain." It is by no means easy, however,

o detect in such a way strain existing in small spherical objects, and the authors might well have been misled. Moreover, the magnitude of the change brought about in the numerical values of physical properties of glasses due to the existence of stresses is not fully realised except by workers on the vitreous state. Pure boric oxide glass and glasses containing boric oxide are particularly susceptible to modification of physical properties according to the rate at which the specimens have been cooled.

Whilst the rapid chilling which the beads of fused boric oxide underwent as the result of dropping small quantities of the molten material into a cold platinum basin made us feel considerable doubt about the beads being strain-free, the very fair concordance between the results for the samples prepared from six different sources at first disarmed criticism. At the time of publication we were engaged in the study of the vitreous system boric oxide–silica, and later we directed our attention to the densities of preparations in this system. Our first determinations on samples prepared from slightly impure boric oxide gave $d_4^{25°}$ 1·843, a value much higher than those of Briscoe, Robinson, and Stephenson. It seemed desirable, therefore, that we should investigate carefully this discrepancy. The account which follows is a brief summary of the work undertaken, the stages enumerated below, however, not necessarily appearing in the sequence in which they were investigated. The several factors considered as possible to account for the discrepancy were five in number.

1. *The Influence of Purity of the Sample.*—The boric acid utilised by us as the source of boric oxide in the earlier experiments was B.P. material containing total impurity of only 0·17%, equivalent to approximately 0·31% in the boric oxide prepared from it by fusion at 1400°. The densities obtained for a well-annealed boric oxide glass from material of the purity stated lay between 1·843 and 1·845 in various determinations.

The same boric acid when recrystallised once from 10% hydrochloric acid and three times from distilled water was found by repeated evaporation with pure methyl alcohol to contain impurity not exceeding 0·02%. The density of eight samples of well-annealed boric oxide glass prepared from this purified acid lay between 1·8435 and 1·8446.

2. *The Influence of the Method.*—Our earlier determinations were carried out by the displacement method, a specific gravity bottle being used, and by critical tests we were satisfied that the densities obtained by means of it were trustworthy to within 0·1%, a trifling error compared with the discrepancy between our values and those of Briscoe, Robinson, and Stephenson. To ensure still greater accuracy in the later stages of the investigation, we used a flotation

method with pentachloroethane and trimethylene dibromide, liquids which had been found suitable by the above authors. The mean of four determinations on well-annealed boric oxide samples in the case of the specific gravity bottle method was 1·8444, and from the flotation method 1·8439.

3. *The Influence of a Trace of Moisture and of the Temperature of Preparation.*—Fused boric oxide is hygroscopic and readily absorbs moisture on its surface, becoming opalescent in the process. A bright bead of boric oxide was balanced in the flotation liquid and then exposed to the atmosphere for 90 minutes; after exposure, it floated on the surface, indicating a diminution in density due to absorption of moisture, which was also indicated visually by a distinct opalescent film.

Experience over several years in the preparation of fused boric oxide glass has indicated that the last traces of water are eliminated with difficulty on fusing boric acid, and a temperature of 900° is insufficient. It appeared to us quite possible that the temperature employed by Briscoe, Robinson, and Stephenson may not have been adequate, for their fusion was carried out in a covered platinum crucible for 4—5 hours at 900°, followed by heating over a Méker burner and a final heating in a Bunsen flame of beads gathered from the crucible by a loop of platinum wire, and it is probable that the maximum temperature attained cannot have exceeded 1000°. Our own samples were prepared by fusion in platinum at 1400°; but in order to test the effect of temperature, a few beads were prepared by fusing boric acid at 1000° for 4 hours and subsequently following the procedure of Briscoe, Robinson, and Stephenson. The lowest density values obtained by us in our series of measurements were with the beads prepared at 1000° [see (5) on p. 2657], and it seems quite likely, therefore, that a small amount of moisture is still retained even after fusion at that temperature.

4. *The Effect of Annealing.*—This factor proved, without doubt, to be the cause of the big discrepancy between our results and those of Briscoe, Robinson, and Stephenson. We had already made measurements of the thermal expansion of fused boric oxide over the whole range of temperature up to the softening point, and had, therefore, been able to deduce the cooling curve requisite for thorough annealing. In a series of measurements on unannealed specimens, obtained by dropping beads into a cold platinum dish, the densities were found to lie between 1·8008 and 1·8067.

The care which must be exercised in annealing glasses required for precise physical measurements is illustrated in the following table, which contains the data for several sets of specimens, one group of them having been cooled more rapidly than the other.

1. *Rate of Annealing.*

Temp.	345°	325°	300°	275°	240°	205°	160°
Time (hours), Curve I ...	0·5	1·5	2·5	3·5	4·5	5·5	6·5
„ „ „ II ...	0·5	2·5	4·5	6·5	8·5	10·5	12·5

2. *Densities by Flotation Method.*

Sample No.	Size of bead (mm.).	Rate of annealing.	Density.
5*a*	3·2 × 4·7 × 5·8	As Curve I	1·8423
5*b*	3·3 × 4·5 × 7·0	„ „	1·8423
6*a*	—	„ „	1·8418
6*b*	—	„ „	1·8414
7*a*	(2·2 × 2·8) (two beads) (2·1 × 2·7)	As Curve II	1·8442
7*b*	(3·2 × 5·3) (two beads) (4·7 × 9·8)	„ „	1·8437
8*a*	—	„ „	1·8440
8*b*	—	„ „	1·8435

When the beads were cooled between 345° and 160° during the comparatively long time of 6½ hours, the densities were still some 2 units in the third place lower than when 12½ hours were devoted to cooling over the same range.

5. *The Influence of Bead Size.*—This question of size is bound up with the question of rate of cooling. In experiments with the boric oxide prepared at about 1000°, the beads being unannealed, a density of 1·8017 was obtained for a bead weighing 0·070 g. and 1·7929 for a bead of 0·111 g.

The results of this investigation indicate, in the first place, that the true density of pure fused boric oxide glass at a temperature between 18° and 25° is not 1·7952, as stated by Briscoe, Robinson, and Stephenson, but is more accurately 1·844 (the mean value of the results by the specific gravity bottle method being 1·8444, and by the flotation method 1·8439). Further, the low figures obtained by these authors are mainly due to inadequate annealing of the specimens, and, probably in a minor degree, to the fusion of the boric oxide at about 1000° only. It is clear from results obtained in this Department that in themselves the variations obtained by these investigators in the density results of boric oxide glass from six different terrestrial sources cannot be used as evidence in favour of the view that the atomic weight of boron varies according to the source of the mineral which contains it.

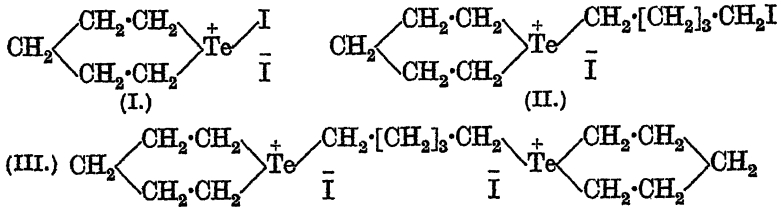
CCCL.—*Studies in Valency. Part XI. Molecular Conductivities and Extinction Coefficients of Derivatives of* cyclo*Telluropentane.*

By FRANK LATHE GILBERT and THOMAS MARTIN LOWRY.

THROUGH the kindness of Professor G. T. Morgan and Dr. H. Burgess, we have been able to extend our investigation of the dimethyltelluronium salts (this vol., pp. 307, 1997) by measuring the molecular extinction coefficients in dry alcohol, and the molecular conductivities in water, of the compounds of *cyclo*telluropentane

FIG. 1.



Molecular extinction coefficients of cyclic tellurium compounds.

recently described by them (*ibid.*, p. 321). In addition to examining the dihalides of the three series, represented by (I), (II), and (III), we have prepared and examined the base $C_5H_{10}TeO$ or $C_5H_{10}Te(OH)_2$, the hydroxy-halides $C_5H_{10}Te(OH)X$, and the *tetraiodide* $C_5H_{10}TeI_4$, of the monocyclic series, and the base $(C_5H_{10})_3Te_2(OH)_2$ of the dicyclic series, as well as the bistribromide and the *bistri-iodide* of the latter series. In the case of the bases, the measurements included a potentiometric titration.

Absorption Spectra.—The molecular extinction coefficients are plotted in Fig. 1 and the most important values are summarised in Table I. Most of the observations followed the course that we

should have anticipated on the assumption that the dihalides may be represented by formulæ such as (I), (II), and (III), where the

covalent and electrovalent halogen are distinguished in the usual way. Thus the cyclic dichloride gave only a general absorption, as in the case of the two dimethyl compounds. The cyclic dibromide, however, gave a step-out, $\log \varepsilon = 3{\cdot}85$ at λ 2600—2850, just as in the case of the α- and β-dimethyl compounds, which gave a similar step-out, $\log \varepsilon = 3{\cdot}7$ and 4·0, respectively, at λ 2600—2800. At longer wave-lengths, however, the absorption of the cyclic dibromide agrees closely with that of the α-dibromide, and is very much less than that of the β-dibromide, which is sufficiently strong in the visible region to give the compound a bright yellow colour, which is lacking both in the isomeric α-compound and in the cyclic dibromide.

The monocyclic di-iodide (I) separates from hot or cold benzene in a purple form, but the surface becomes yellow if the solution is allowed to dry on the crystals. When the purple form is heated, it begins to pass into the orange form at about 90° and changes rapidly at 110°; the purple form also becomes orange in boiling water before it dissolves. The transition temperature is therefore below 100°, but is not easy to determine precisely on account of the lag in the transformation, even with rising temperatures. The reverse change from orange to purple takes place in a few minutes at the ordinary temperature, but is slower if the orange form has been kept for some time above 100°. The clear orange crystals which are obtained when the di-iodide separates from hot carbon tetrachloride may persist for some weeks at atmospheric temperature before becoming purple, even when exposed to air and light; and a crystal which exhibits both colours may persist for some days before it changes completely into the purple form.

A careful comparison showed that the absorption spectra of the two forms in cold alcoholic solutions are identical within the limits of experimental error. The spectrum shows the twin maxima of the "iodoform band," the maximum extinction coefficients being $\log \varepsilon = 3{\cdot}9$ at 3380 and $\log \varepsilon = 4{\cdot}05$ at 2770. The intensities of two maxima are similar to those of the dimethyl di-iodides (of which

the α-compound gave log ε = 3·7 and 4·05, whilst the β-compound gave log ε = 3·8 and 4·25), but in the visible region the absorption of the cyclic di-iodide again corresponds with that of the α-dimethyl di-iodide, since the curve falls away steeply from the maximum, instead of showing the wide extension of the foot of the band which accounts for the deeper colour of the β-di-iodide.

The cyclic di-iodide (I) also resembles the α-dimethyl di-iodide, and differs from the β-di-iodide in that it readily forms a tetraiodide $[C_5H_{10}TeI]^+I_3^-$. This compound, which we prepared by mixing equimolecular solutions of the di-iodide and of iodine in chloroform, and boiling the mixture under reflux for 10 minutes, separated as a black solid, and crystallised from methyl alcohol in shining, black crystals. It melts at 82—84° to a black oil, which is slowly dissolved (like the di-iodide) by boiling water, but to a very limited extent. Its absorption spectrum is similar to that of the di-iodide, but of practically twice the intensity throughout, since both ions of the salt give rise to twin maxima at nearly the same wave-length and intensity (log ε = 4·28 and 4·45, obs.; 4·25 and 4·43, calc.).

According to the views expressed in our previous paper, *both* atoms of halogen in the dihalides of type (III) should be ionised in the same way as in the trimethyltelluronium halides. This conclusion is confirmed by the fact that the di-iodide $(C_5H_{10})_3Te_2I_2$ is readily converted into a black hexaiodide, $(C_5H_{10})_3Te_2I_6$. This compound, which we prepared by mixing the cyclic di-iodide with 2 mols. of iodine in chloroform, and boiling the mixture under reflux for 10 minutes, separated as a black solid melting at 127—129°, but could not be recrystallised on account of its sparing solubility. In order to observe its absorption spectrum, 0·0125 g. was dissolved in 10 c.c. of dry methyl alcohol, and the solution examined at *M*/5000. The spectrum showed the twin maxima of the tri-iodide ion, with the same two-fold intensity as in the monocyclic tetraiodide (log ε = 4·25 and 4·44, obs.; 4·30 and 4·50, calc.), but with a wider "foot" in the visible region of the spectrum, to correspond with the greater absorption in this region of the tri-iodide ions. The hexabromide, described by Morgan, was also examined in methyl alcohol, and gave a general absorption with clear indications of a maximum, log ε >4, just beyond λ 2400, and the beginnings of a step-out, which could not be traced to longer wave-lengths than 3400 on account of the limited solubility of the product (the tribromide ion in $C_6H_4Br\cdot\overset{+}{N}Me_3\overset{-}{Br}_3$ gives a maximum, log ε = 3·4 at λ 2600, and a step-out, log ε = 1·8 at λ 3900).

The remaining compounds of series (II) and (III) gave only a general absorption of light, in agreement with the conclusion that

none of the halogen is joined to the metal by a covalent bond. The rather heavy general absorption of the iodide (II) can be explained by the presence of the group $-CH_2I$, but this explanation is not available in the case of the iodide (III).

Molecular Conductivities.—The methods used have already been described (this vol., p. 308), but attention may be directed to the fact that a few sparingly soluble compounds, which it was undesirable to hydrolyse by boiling with water, were dissolved in a minimum quantity of alcohol and diluted with not less than 20 volumes of conductivity water. The validity of the corrections applied to these solutions has already been demonstrated in the case of α-dimethyltelluronium di-iodide (this vol., p. 313).

The molecular conductivities shown in Table II are for the most part in agreement with the values which we should have predicted from the preceding formulæ, with the help of the data already obtained for the dimethyl compounds. Thus, the dihalides of type (II) behave as *binary* electrolytes, like the hydroxy-halides of the dimethyl series, or the simple halides of the trimethyl series, and give values of $\Lambda^{25°} = ca.$ 100. In the same way, the dihalides of type (III) behave as *ternary* electrolytes, giving $\Lambda^{25°} = ca.$ 200. The dihalides of type (I), however, gave the same anomalous values, $\Lambda^{25°} = ca.$ 500, which were observed previously in the dimethyl series, so that once more it was clear that, whereas one halogen is *ionised* more or less completely, the other is *hydrolysed* to a similar degree. The tetraiodide of type (I) gave similar values, $\Lambda^{25°} = ca.$ 500, and was evidently hydrolysed according to the scheme

$$[C_5H_{10}TeI]I_3 + H_2O \rightleftharpoons [C_5H_{10}TeOH]I_3 + HI.$$

An unexpected result was obtained, however, when the bis-tribromide of type (III) and the analogous bis-tri-iodide were dissolved in boiling water and cooled to 25°, since, instead of behaving as ternary electrolytes, with $\Lambda^{25^\circ} = ca.\ 200$, their solutions gave molecular conductivities of the order $\Lambda^{25^\circ} = 1000$. This anomaly can be explained most readily by supposing that the compounds are decomposed according to the scheme

$$C_5H_{10}{:}TeI_3{\cdot}C_5H_{10}{\cdot}TeI_3{:}C_5H_{10} \longrightarrow 2C_5H_{10}{:}TeI_2 + C_5H_{10}I_2$$
$$\longrightarrow 2[C_5H_{10}{:}TeOH]I + 2HI + C_5H_{10}I_2$$

The conclusion that the high conductivities of this compound are due to a progressive decomposition was established by dissolving the polyiodide in cold alcohol and diluting it with cold water, whereupon we found $\Lambda^{25^\circ} = 106$, reckoned on the total concentration of the polyiodide, part of which, however, was still undissolved. When the solution was warmed, the value rose to $\Lambda = 136$ at 40°, and $\Lambda = 315$ at 100°. Finally, after some minutes' boiling, when all the material had dissolved, the conductivity rose to $\Lambda^{25^\circ} = 794$, or $\Lambda^{25^\circ} = 930$ when corrected for the alcohol used as solvent, in good general agreement with the values recorded in Table I.

The hydroxy-halides, which are formed by the hydrolysis of the monocyclic dihalides, were prepared by mixing the free base (see below) and the dihalides in molecular proportions, and were found to behave as strong binary electrolytes, just as in the case of the hydroxy-halides prepared from Vernon's salts. The conductivities agree more nearly with those of the α-series than of the β-series, but we cannot lay any stress on this fact, as we have not yet found a satisfactory explanation of the higher values recorded for the latter compounds. In the case of the free bases, however, where there is a much greater contrast between the α- and β-series, the conductivities of the cyclic compound are much lower than those of Vernon's β-base, and differ only to an insignificant extent from the very small values already recorded for the α-base at similar dilutions.

Potentiometric Titration of the Bases.—(*a*) The *monocyclic base*, $C_5H_{10}Te(OH)_2$ or $C_5H_{10}TeO$, was prepared by grinding the dibromide with freshly prepared silver oxide; when the solution was evaporated to dryness in a vacuum, the base was obtained as a colourless solid, but the quantity was not sufficient for an analysis to show whether the base was anhydrous or hydrated. On re-dissolving, it gave the same reactions as the original base with acids, with silver nitrate, and with ferric chloride, and hence was not converted into an isomeride under the conditions which cause Vernon's α-base to change into the β-base. With hydriodic acid, the base gives a

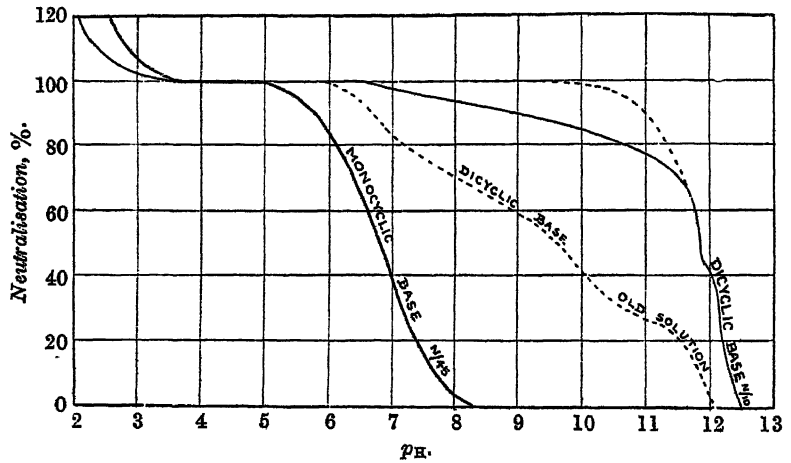
canary-yellow precipitate, m. p. 136—137°, which is probably the orange form of the cyclic di-iodide, m. p. 135—136°. This precipitate does not change colour when heated to its m. p., but turns purple (or dark red) when compressed with a spatula, and retains this colour when the pressure is released. The dark red form reverts to the yellow form at 115°, but this does not change back to red on cooling.

A potentiometric titration was made, with a glass electrode, of an N/45-solution, which was neutralised with N-hydrochloric acid. The resulting curve is plotted in Fig. 2. The free base gave p_H = 8·3, in close agreement with the value for the α-dimethyl base. The equivalence point was p_H = 4·1, the values at 98% and 102% neutralisation being 5·1 and 3·4, a range of 1·7 units. At half-neutralisation p_H = 6·8, whence $-\log K_B$ = 7·2 and $K_B = 6·3 \times 10^{-8}$. The titration curve almost coincides with that of Vernon's base; but it differs fundamentally from the curve for the β-base, in that it shows no sign of an intermediate inflexion.



(*b*) The *dicyclic base*, $(C_5H_{10})_3Te_2(OH)_2$, was prepared by the action of silver oxide on the di-iodide or dibromide. In order to

obtain a good yield, it was necessary to grind the di-iodide with silver oxide for 2—3 hours, whereas ½ hour is ample for the conversion of the monocyclic di-iodide and the dimethyl di-iodides into the corresponding bases. A quantitative experiment with a weighed quantity of the dicyclic di-iodide showed that under these conditions the neutral point with methyl-orange corresponds closely with that calculated for neutralisation of both hydroxyl groups of the base. After evaporation and dissolution, the base gave the same reactions as before towards silver nitrate, picric acid, hydriodic acid, and ferric chloride.

A curve for the potentiometric titration of an $N/10$-solution of the dicyclic base with a glass electrode against N-hydrochloric acid

FIG. 2.

Potentiometric titrations.

is shown in Fig. 2. The solution was freshly prepared, since less than 1 hour elapsed between the preparation of the base and the commencement of the titration. The dicyclic compound is a strong base, which gave $p_H = 12{\cdot}5$ at $N/10$ or $M/20$, in marked contrast with the weak monocyclic base, which gave $p_H = 8{\cdot}3$ at $N/45$. A slight break, corresponding to the neutralisation of the first hydroxyl group, was observed at 50% neutralisation, but this could easily have been obliterated in drawing the diagram. At about 75% neutralisation the readings became unstable and began to drift towards the alkaline side, the largest drift being about 44 millivolts or 0·8 in the value of p_H. The values plotted in Fig. 2 were obtained after an interval of about 15 minutes, when the drift had become very slow; but we cannot be sure that they were the final equilibrium values, and it is possible that after long delay the values might have drifted

to those required to give the typical (broken) curve for a strong base. At 80—100% neutralisation the drift was more rapid, and at 100% steady values were obtained immediately.

The abnormalities described above were confirmed in almost every detail by a duplicate determination with a freshly prepared $N/14{\cdot}5$ (or $M/29$)-solution. A third solution, of concentration $N/14$, which had been made up for about 9 days, however, gave a more abnormal curve, which straggled across from an initial value $p_H = 12$, to $p_H = 6$ at 100% neutralisation. Similar abnormalities were observed in the conductivities of these solutions. Thus the equivalent conductivities of the solution which was used for the first potentiometric titration, when examined 2 days after it had been prepared, had the following values at 20° :

v	71·5	143	286	572	1144
$\Lambda^{20°}$	190	195	197	197	196

Since the mobility of the bivalent kation $(C_5H_{10})_3Te_2^{++}$ is about 34×2, whilst that of the hydroxyl ion at 20° is about 178, these are normal values for a strong base with $\Lambda_\infty^{20°} = ca.\ 210$. On the other hand, the third solution, when 10 days old, gave the following equivalent conductivities at 25° :

v	100	200	400	800	1600
$\Lambda^{25°}$	116	122	126	129	129

These conductivities are about one-third less than those recorded for the first solution, whereas they should be about 8 units higher to allow for a temperature difference of 5°.

Although we cannot offer any precise explanation of these anomalies, they are clearly due to a locking-up of the basic properties of the hydroxide by a reversible process which may be compared with the formation of a pseudo-base. This view is supported by the fact that a progressive decrease of conductivity was observed in a freshly prepared solution of the base, which gave the following readings (R = resistance; t = time, in hours):

t ...	0	0·5	1	2·8	4·5	6	22	46	95	101	119	142
R ...	88·5	90·1	90·8	90·9	91·1	91·3	93·8	96·8	101·5	102	103·5	105
$\Lambda_{39}^{25°}$	142										121·5	119·5

In this case, the conductivity fell progressively from an initial value, which was approximately mid-way between those of the first and third solutions, to a final value, which was approximately the same as the latter. The strength of the solution, as tested by titration with methyl-orange as indicator, however, was exactly the same at the end of 6 days as when tested initially. On the other hand, another freshly prepared solution had already reached a steady value $\Lambda_{47}^{25°} = 117$ at the end of 5 minutes from the time when the

base was extracted from the silver oxide, and maintained it with small fluctuations during a period of 2 days :

t	0·1	0·4	2·5	4	5·5	21·5	30	46	48
R	86·0	86·0	85·4	85·0	85·6	85·2	87·5	87·0	87·0

These observations show that solutions of the dicyclic base are subject to wide variations of properties, depending on the age of the solutions and on other factors which are still obscure; but no more material was available to enable us to pursue the enquiry any further.

Action of Alkalis on the Cyclic Di-iodide.—The most striking contrast between Vernon's α- and β-compounds is found in the fact that the α-di-iodide yields sparingly soluble basic iodides when acted on by alkalis, whilst the β-di-iodide undergoes a molecular rearrangement, which can be compared with a pinacol–pinacolin transformation, since it gives rise to trimethyltelluronium iodide as one of the products. In order to find out which type of behaviour is characteristic of the monocyclic iodides, the purple di-iodide was boiled with a concentrated aqueous solution of potassium carbonate, and evaporated to a small bulk. The colourless crystals which separated decomposed at 195° and contained 39—41% I, whereas the monoxyiodide $(C_5H_{10})_2Te_2OI_2$ would require 38·3% I. The compound resembled Vernon's α-monoxyiodide in being soluble in water and neutral to methyl-orange, but differed from it in that it did not change colour in air.

A colourless solid obtained by grinding the solid di-iodide with concentrated aqueous ammonia turned yellow on exposure to the air or when heated at 100°; it contained 34% of iodine, gave a neutral aqueous solution, and blackened and decomposed at 150°.

The products obtained by the action of potassium carbonate and of ammonia on the monocyclic di-iodide are obviously quite distinct from the dicyclic di-iodide, $(C_5H_{10})_3Te_2I_2$, which would be the analogue of the trimethyltelluronium iodide formed in Vernon's transformation of the β-salt; on the other hand, their composition and properties are those of basic iodides, and therefore confirm the conclusion that in this respect also the cyclic di-iodide exhibits the behaviour of an α- rather than of a β-salt.

Summary.

Measurements have been made of the molecular conductivities and extinction coefficients of the cyclic tellurium compounds recently described by Morgan and Burgess. The tertiary salts behave as strong electrolytes, like $TeMe_3I$, but the secondary salts resemble $TeMe_2I_2$ in losing one molecule of halogen by hydrolysis,

giving rise to hydroxy-halides. Observations of the conductivities of the base and of the form of the curve obtained from a potentiometric titration, together with the absorption spectrum of the iodide and its behaviour towards iodine and towards alkalis, show that the cyclic compounds resemble Vernon's α- (or *trans*-) series of compounds rather than the isomeric β- (or *cis*-) compounds.

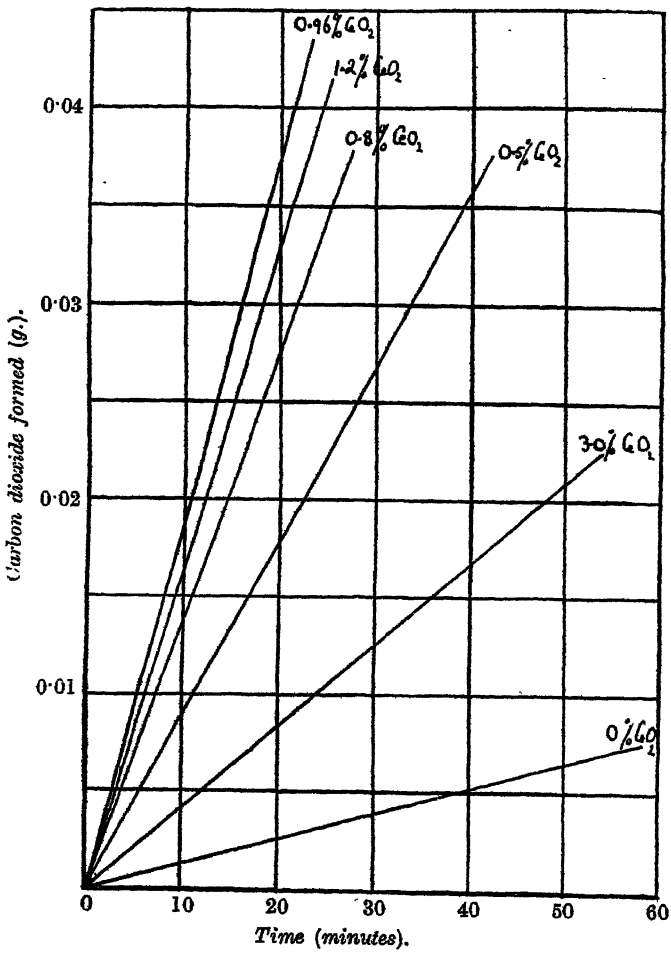
We are indebted to Professor Morgan and Dr. Burgess for specimens of the cyclic tellurium compounds, and to the Department of Scientific and Industrial Research for a maintenance grant to one of us (F. L. G.) during the period within which the research now described was carried out.

CHEMICAL LABORATORY,
UNIVERSITY OF CAMBRIDGE. [*Received, June 7th*, 1928.]

CCCLI.—*An Investigation on the Ceria–Thoria Catalysts.*

By A. B. GOGGS.

IT has been shown by Swan (J., 1924, **125**, 780) that, of all the mixtures of ceria and thoria, that used in the gas mantle (CeO_2 1%; ThO_2 99%) is the most efficient for bringing about the oxidation of hydrogen. The present investigation was undertaken to determine whether this mixture was also the most efficient for the combustion of other gases, the gas chosen being carbon monoxide.



Thorium nitrate was purified by the method of Neish (*J. Amer. Chem. Soc.*, 1904, **26**, 781), the details being essentially the same as those used by Swan (*loc. cit.*). Cerium ammonium nitrate was prepared by the method of Imry (*Z. anorg. Chem.*, 1927, **164**, 781) and recrystallised three times from 10·5*N*-nitric acid. Carbon monoxide, prepared from redistilled formic acid and pure sulphuric acid, was mixed with pure oxygen, prepared from potassium permanganate, in the proportion of 2 : 1 by vol.

The solutions of the nitrates were mixed in the requisite proportions and the mixed oxalates were precipitated with recrystallised oxalic acid and boiled with a slight excess of oxalic acid to reduce the ceric salt to the cerous state, the same quantity of oxalic acid being used in each case. The precipitates were filtered off, and ignited to constant weight at as low a temperature as possible; they were then sieved, made into a paste with water, spread evenly on thin glass slips (2·2 × 0·4 mm.), and dried at 140° for 5 hours.

Experiments were at first conducted in an apparatus similar to Swan's (*loc. cit.*), but unsatisfactory results were obtained on account

of the accumulation of the carbon dioxide over the catalyst and the impossibility of starting to take readings at corresponding times. The following experiments were made by passing the carbon monoxide–oxygen mixture (freed from carbon dioxide) at constant

FIG. 1.

pressure through a flow-meter over the catalyst in a hard-glass tube in the furnace, collecting the carbon dioxide formed in two flasks containing barium hydroxide of known strength, and titrating the excess of barium hydroxide, phenolphthalein being used as indicator. Care was taken that the catalyst was always in the same part of the tube so that the pre-heating of the gases should be the same in all

cases. The glass slip was put flat on the bottom of the tube. The temperature employed was 485°.

The following were the results obtained, each experiment being made with a different catalyst-slip. It is seen that the rate of formation of carbon dioxide (dc/dT) attains a maximum at 0·96% of ceria (see also Fig. 1), and hence that the catalyst which Swan had found to be most efficient in the oxidation of hydrogen is also the most efficient for that of carbon monoxide.

[*Received, July 19th*, 1928.]

CCCLII.—*Studies in the Composition of Coal. Oil-yielding Constituents.*

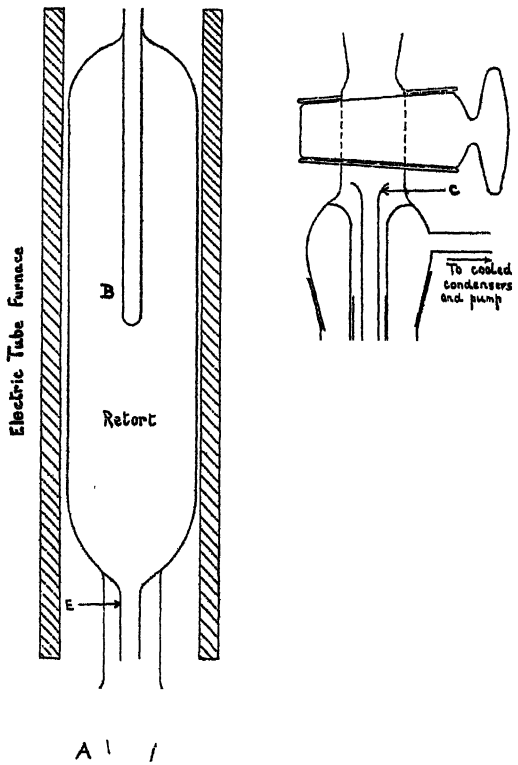
By RONALD HOLROYD and RICHARD VERNON WHEELER.

BITUMINOUS coal being a conglomerate of different types of compounds which decompose at different temperatures, yielding characteristic liquid and gaseous products, it is reasonable to suppose that by the slow destructive distillation of the coal as a whole the contributions of each type of compound to the distillates might be recognised. In particular, it would seem probable that those constituents of the coal which, when separated therefrom by means of solvents, are found to melt below 100° (see Cockram and Wheeler, J., 1927, 700) should become liquid and flow from the coal at quite low temperatures. The work of Burgess and Wheeler (J., 1914,

105, 131) and, more recently, of King and Willgress (Fuel Research Board Tech. Paper No. 16, 1927) is significant in this connexion.

We have carried out slow destructive distillations, in a vacuum, of a number of bituminous coals, using varieties which had already been studied by solvent analysis and other means, so that their general character was known. We record in detail in this paper the results obtained with one coal, bright coal (mixed vitrain and clarain) from the Wigan Six Foot seam.

The main conclusions to be drawn from the results (which experiments with other coals amply confirm) are: (1) That the hydrocarbons and resins, extractable from the coal by organic solvents, yield a high proportion of the oils obtained on distillation, the former being distilled unchanged, quantitatively, and the latter partly distilled and partly decomposed. (2) That the coal has a definite decomposition point, which is not appreciably affected by changes in the experimental conditions. With the Wigan Six Foot coal the decomposition point occurs at 318°. Characteristic products of this decomposition, which is of the ulmin constituents of the coal, are water and phenolic compounds. As soon as the decomposition point of the coal has been passed, its character, as evinced by its behaviour towards solvents, its caking-power, and its reactivity in general, undergoes a sudden and marked change.



Experimental.

The method of experiment was similar to that used by Burgess and Wheeler (*loc. cit.*). A charge of 250 g. of the undried coal, ground to pass a 20-mesh and remain on a 50-mesh sieve (I.M.M. standard), filled a cylindrical retort of Jena glass, fixed vertically with its mouth downwards. The retort (see Fig. 1), which was heated electrically in a tube furnace specially designed to secure a uniform temperature throughout its length, was connected by a ground glass joint, A, through a series of three condensers, to an automatic mercury Sprengel pump. A glass tube, B, reaching to the centre of the charge of coal, was fused into the head of the retort for the reception of a thermo-couple. A second thermo-couple was lashed to the outer wall of the retort. The required temperature was regulated by means of the outside thermo-couple. About 12 hours elapsed before the inside thermo-couple recorded the same temperature as the outside, but thereafter both records remained constant and identical.

A difficulty encountered with regard to the collection of the less fluid oils distilled from the coal, which it was desired to separate at intermediate stages of the heating, arose through their condensation at the neck of the retort, whence they could be removed only after

dismantling the apparatus. To obviate this difficulty, the arrangement shown in Fig. 1 was devised. A glass tube, C, bearing a small cylinder of soft iron at its lower end, was placed within a test-tube, D, and the two were inserted within the first of the series of three condensers connected to the retort. When the apparatus was assembled for an experiment, the whole being thoroughly evacuated, the tube C was raised by means of a solenoid, so that its upper end fitted closely over the mouth of the retort at E. It was then gripped in position by slightly turning the wide-bore tap, F. At any stage in the distillation of the coal the tube C could be withdrawn below the tap F (which could then be closed) and the oils that had condensed within it examined.

FIG. 1.

Method of Carrying out a Distillation.—After evacuation of the apparatus, the temperature of the charge of coal was slowly raised to 100° and maintained continuously during 120 hours. Any liquid and gaseous products evolved were collected, the former in the condensers, the second and third of which were cooled by immersion in solid carbon dioxide dissolved in ethyl ether, and the latter over mercury at the Sprengel pump. The temperature was now raised over the second desired range, 48 hours being taken in doing so, and maintained at the higher value during 120 hours, the liquids and gases evolved being collected as before. And so for each temperature range. The pressure within the apparatus, even at periods of maximum gas-evolution, never exceeded 3 and was usually less than 1 mm.

Examination of Liquid Products.—The liquid products were collected in two portions over each temperature range: (1)

and "light oils" condensing at −80° in the two cooled receivers; and (2) "heavy oils" condensing at atmospheric temperature in the first receiver. The "light oils," consisting mainly of light petroleum, were weighed but not closely examined. The "heavy oils" were analysed in the following manner. A chloroform solution of them was washed successively with dilute solutions of sodium carbonate, potassium hydroxide, and sulphuric acid, from which solutions acidic, phenolic, and basic oil fractions were recovered. The residual neutral oil was extracted in a Soxhlet apparatus successively with light petroleum, ethyl ether, and chloroform. The extract by light petroleum, consisting mainly of hydrocarbons, was treated with concentrated sulphuric acid, thereby making a separation of saturated from unsaturated compounds, and in some experiments the saturated compounds were treated with fuming sulphuric acid and nitration mixtures for the removal of aromatic compounds.

Distillation of Wigan Six Foot Coal.—The sample of coal used for these experiments was the bright portion of the seam, a clarain with numerous streaks of vitrain. It contained 2·7% of ash and the ultimate analysis, on the ash-free dry coal, was: C, 81·8; H, 5·5; O, 9·24; N, 1·52; S, 1·94. Solvent analysis (see Cockram and Wheeler, *loc. cit.*) by pyridine and chloroform gave: Insoluble in pyridine (α), 81·54; soluble in pyridine but insoluble in chloroform (β), 12·34; soluble in both pyridine and chloroform (γ), 6·12. The γ-compounds contained: Soluble in light petroleum (γ_1), 1·53; soluble in ethyl ether (γ_2), 1·46; residue (γ_3 and γ_4), 3·14 (all expressed as percentages on the ash-free dry coal).

Table I records the production of gaseous and liquid distillates by successive stages up to 550°.

The gases evolved up to 100° were mainly the higher paraffins. No marked increase in the rate of evolution of gases occurred up to 300°, but the proportion of paraffins decreased and that of oxides of carbon increased. Hydrogen was first noticed in the gases evolved over the range 300—320°, but even at 350° the gases contained no more than 1% of hydrogen, the fraction collected over the range 320—350° consisting mainly of the paraffins (ratio C/A on explosion analysis, 1·50), with about 10% of higher olefines. At 300°, hydrogen sulphide first made its appearance, a mobile oil, condensed at −80°, with a pungent garlic-like odour being evolved simultaneously.

The coal, which had previously been exhausted at room temperature during 4 days, lost 5% by weight of moisture up to 100°. This is not recorded as a product of distillation in Table I. Very little water was evolved between 100° and 300°. The "light oils"

were noticed first at 150° and the "heavy oils," condensing at atmospheric temperature, at 225°. The first runnings of heavy oils were mobile and of a red colour. They continued to be of this character up to 300°, very little gas being evolved meanwhile. At 318°, there was a sudden acceleration in the production of gases, water, and oils. At this temperature, phenolic and acidic compounds were noticed in the oils for the first time, but the bulk consisted of unsaturated hydrocarbons. At 330°, oils of another type were distilled simultaneously with the hydrocarbons. These were viscous and insoluble in light petroleum but soluble for the most part in ethyl ether. The production of heavy oils ceased at about 390°, the greater proportion being distilled over the range 300—375°. Light oils continued to be evolved in small quantities above 400° and water up to 550°, the highest temperature employed. Analyses of different fractions of the heavy oils are given in Table II, comparison being made with the γ_1 and γ_2 extracts of the original coal.

TABLE II.

Analyses of Oil Fractions.

Material.	Per cent. on ash-free dry coal.	Carbon %.	Hydrogen %.
Total heavy oils up to 300°	1·33	87·3	9·25
γ_1 extract from the coal freed from resins	1·20	86·5	9·10
Sat. hydrocarbon oils up to 300°	0·70	86·8	10·10
Sat. hydrocarbon oils from γ_1 extract ...	0·76	86·4	10·50
Ether-soluble portion of oil first evolved at 330°	1·24	81·8	7·09
γ_2 extract from the coal	1·46	81·6	8·40

The amount of γ_1-extract from the coal was 1·53%. The removal of resinous compounds by Robinson's method (J., 1925, **127**, 768) left 1·20% of a hydrocarbon oil. Both in quantity and in composition this oil corresponded closely with the "heavy oil" distilled from the coal up to 300°. Moreover, both the distilled oil and that removed from the coal by solvents lost 40% by weight on treatment with concentrated sulphuric acid, and from the saturated hydrocarbons remaining, of both oils (see Table II), a white solid hydrocarbon, m. p. 56—58°, was obtained by precipitation on cooling from boiling acetone. This close similarity (and the fact that very little gas accompanied the oils distilled from the coal) suggests that the primary oil obtained below 300° was yielded, without decomposition, by the γ_1-fraction. With all the coals we have examined in this manner there is close correspondence, both in quantity and in composition, between the hydrocarbon oils distilled from the coals below 300° and the γ_1-extracts (freed from resinous compounds).

The viscous oil that first made its appearance at 330° could be separated from the hydrocarbons by treatment with light petroleum and ethyl ether. On evaporation of the solvent, a red-brown solid was obtained similar in composition and general character to the resinous γ_2-extract from the coal. The quantity of this resinous material distilled from the Wigan Six Foot coal approximated to that of the γ_2-fraction, but with other coals the quantity may be considerably less.

Two fractions of the primary liquid distillation products of bituminous coal can thus be identified with the γ_1 (hydrocarbon) and γ_2 (resinic) constituents that are removed from the coal by solvents, and can be regarded as having been liquated from the coal conglomerate, not produced by decomposition of the coal substance. The thermochemical decomposition point of the coal is marked by a copious evolution of gases and water and by the appearance of phenolic and acidic compounds. With the Wigan Six Foot coal this thermochemical decomposition point was 318°. The work of Jones and Wheeler (J., 1914, **105**, 140) shows that the phenolic compounds are products of decomposition of the ulmin portion of the coal exclusively. They are accompanied by much gas and water.

Examination of Residues from Distillation of Wigan Six Foot Coal.—In view of the close correspondence between the γ_1 (hydrocarbon) and γ_2 (resinic) fractions, extractable from the Wigan Six Foot coal by solvents, and certain portions of the oils obtained on distillation of the coal, it was considered desirable to examine the solid residues remaining after distillation at different temperatures, more particularly as to their contents of substances extractable by solvents.

To this end a series of distillations of different charges of the same coal was carried out, in the manner already described, heating being stopped at 250°, 280°, 300°, 320°, and 350°, respectively. Each residue, after being washed with chloroform in the cold to remove traces of liquid distillates that might be adhering to it, was subjected to "solvent analysis" according to the scheme outlined by Cockram and Wheeler. The results are in Table III.

The general character of the changes that have taken place during the distillations is shown in Fig. 2. The residue after distillation at 300° contained but a small quantity of material extractable by light petroleum after fractionation with pyridine and chloroform (*i.e.*, material corresponding with the γ_1-fraction of the original coal). This, on examination by Robinson's method, was found to be wholly resinic. Corresponding, therefore, with the liquid hydrocarbons collected from the distillation at this temperature, the coal residue is devoid of an equivalent amount of material of like nature which, before the coal was heated, could be extracted from it by solvents. This, coupled with the fact, already recorded, that but little gas is evolved at this temperature, is strong presumptive evidence that the oils distilled were originally present, as such, in the coal. Additional evidence is afforded by the fact that the hydrocarbon oils collected from the distillation of the coal up to 300° can be redistilled unchanged (in a vacuum) over a temperature range but little lower than that at which they were distilled from the coal.

Heating at each stage up to 320° caused in the residues an increase in the amounts of extracts corresponding with the γ_2-fraction of the original coal. This was probably derived from the resin-like constituents originally soluble only in chloroform or acetone (the γ_3- and γ_4-fractions), since the effect of moderate heat on them

to render them in part soluble in ethyl ether, when they are recognisable as resins.

The residue after heating at 350° had lost most of the original ether-soluble material (γ_2-fraction), and, as already recorded, an identical material first appeared in the liquid distillation products just below this temperature (at 330°) and could be separated from them as a red-brown solid. The source of this solid is thus the extractable resins of the coal, but complete distillation of the resins, unchanged, from the coal cannot be presumed (as it can with the hydrocarbons), for with the majority of coals less is obtained by distillation than by extraction. Moreover, this resinous distillate from the coal cannot be redistilled unchanged. On distillation at 400° in a vacuum, for example, the distillate amounts to about 70% of the original, is more fluid and is soluble (60%) in light petroleum, and the undistilled residue is soluble in chloroform.

FIG. 2.

Two observations suggest the manner in which this resinous distillate is yielded by the coal. When the duration of heating was much prolonged, the temperature at each stage being maintained during 720 instead of the usual 120 hours, a quantity of the ether-soluble resin was present in the distillate at a rather lower temperature than before (at 310°), and some could be washed out of the residual coal charge with cold chloroform, suggesting that the first action of heat on the resinic constituents of the coal was to liquate them to the surface of the coal particles. Further, when a number of coals are examined in the manner described in this paper, it is found that the relationship between the quantity of resins extractable from the coal by solvents and obtained from them by distillation is dependent on the amount of hydrocarbon oil that accom-

panies them. The greater the quantity of hydrocarbon oil distilled from the coal, the nearer does the quantity of resins distilled correspond with the quantity extractable from the original coal by solvents. The suggestion is that, during the heating of the coal, the resins are first melted and then in part carried away by the hydrocarbon oil vapours that are being distilled at the same time. No doubt such of the resins as are not vapour-distilled in this manner are later decomposed or modified by the heating in much the same manner as they are found to be on redistillation, becoming mobile and for the most part soluble in light petroleum.

The thermochemical decomposition point of the coal is sharply defined and is unaltered by changes in the experimental conditions. With the Wigan Six Foot coal the decomposition point is 318° whether the distillation is effected in a vacuum or at atmospheric pressure. Heating during one month at 310° causes no appreciable decomposition.

Marked by a copious evolution of gases, water, and oils, the decomposition point of a coal is the beginning of the breakdown of the ulmin constituents (the major part of the coal), and thereafter the effect of heat is to produce profound changes in the coal substance. These changes, apparent on examination of the solid distillation residues, affect not only the behaviour of the coal towards solvents (see Fig. 2) but its reactivity in general (with oxygen, for example) and its caking power. A further communication, in which the decomposition points of a number of coals are compared, will deal with this subject more fully.

Whilst the characteristic liquid products of destructive distillation of the ulmin portion of the coal are phenolic and acidic compounds, hydrocarbon oils are also produced and contribute to the yield of such oils obtained on heating the coal above its decomposition point. For the most part, however, the hydrocarbon oils obtained over the higher temperature ranges are derived from the organised plant entities (mainly spore exines and cuticular tissues) preserved in the coal. Details of the researches on which this conclusion is founded will be given later.

The work described in this paper forms part of a research on the constitution of coal which we are carrying out for the Safety in Mines Research Board, to whom our thanks are due for permission to publish the results.

SHEFFIELD. [*Received, August 3rd*, 1928.]

CCCLIII.—*A Synthesis of Behenolic Acid.*

By RAMAKANTA BHATTACHARYA, SHANKAR RAO SALETORE, and JOHN LIONEL SIMONSEN.

AN analytical investigation led Mirchandani and Simonsen (J., 1927, 371) to conclude that *iso*erucic acid is an inseparable mixture of Δ^{11}-*heneicosene*-1-*carboxylic acid* (I) and Δ^{13}-*heneicosene*-1-*carboxylic acid* (II).*

$CH_3\cdot[CH_2]_8\cdot CH{:}CH\cdot[CH_2]_{10}\cdot CO_2H$ (I.) $CH_3\cdot[CH_2]_6\cdot CH{:}CH\cdot[CH_2]_{12}\cdot CO_2H$ (II.)

Syntheses of these two acids are desirable to establish this, but unfortunately the methods available for syntheses of this type are somewhat limited (compare Robinson and Robinson, J., 1925, **125**, 175). The most direct method would appear to be the preparation of the corresponding acetylenic acids, since the reduction of these to the ethylenic acids is readily performed, and we decided to explore first the synthesis of behenolic acid (III).

$C_8H_{17}\cdot C{:}CNa$ (IV.) $+ CH_2Br\cdot[CH_2]_{10}\cdot CO_2Me$ (V.) $\longrightarrow CH_3\cdot[CH_2]_7\cdot C{:}C\cdot[CH_2]_{11}\cdot CO_2H$ (III.)

The method adopted was the condensation of the sodium derivative of decinene (IV) with *methyl* 11-*bromododecoate* (V). Decinene was prepared by Picon's method (*Compt. rend.*, 1919, **169**, 32) from octyl iodide and sodium acetylide: we have found that the reaction proceeds best at 180°. For the synthesis of the bromo-ester, decane-1 : 10-dicarboxylic acid was prepared in considerable quantity by Walker and Lumsden's method (J., 1901, **79**, 1191): their methods for the preparation of 10-bromoundecoic acid and its conversion into the dibasic acid have both been improved.

Methyl hydrogen decane-1 : 10-*dicarboxylate*, obtained by the partial hydrolysis of the dimethyl ester, was reduced to 11-*hydroxydodecoic acid*, m. p. 78—79°, by the method of Grün and Wirth (*Ber.*, 1922, **55**, 2216). This acid does not appear to be identical with any of the hydroxydodecoic acids previously described. It was thought that it might be identical with the acid isolated by Power and Rogerson from *Ipomœa purpurea* (*Amer. J. Pharm.*, 1908, **80**, 251), but direct comparison with a specimen of this acid, for which we are much indebted to Dr. T. A. Henry, showed this not to be the case. The hydroxy-acid, when treated with hydrogen bromide in methyl-alcoholic solution, was converted into the

* In the paper referred to (p. 373), the acids (I) and (II) are wrongly named as derivatives of docosene.

required bromo-ester. Although this crystallised well, we have not succeeded in obtaining it quite pure. Condensation of sodiodecinene and methyl 11-bromododecoate in xylene at 160° resulted in the formation of a liquid ester which, on hydrolysis, gave an acid crystallising from methyl alcohol in needles, m. p. 57°, identical in all respects with a specimen of behenolic acid prepared from erucic acid.

EXPERIMENTAL.

10-*Bromoundecoic Acid.*—To a mechanically stirred and well-cooled solution of hydrogen bromide in toluene (HBr, 10—15%) the requisite amount of undecylenic acid was gradually added. After 2—3 hours, the bromo-acid, which had crystallised (m. p. 51°), was collected; a further quantity could be obtained by cooling the filtrate in a freezing mixture. The bromo-methyl ester, b. p. 165°/10 mm., prepared by the action of methyl alcohol and sulphuric acid (Found: Br, 28·2. Calc.: Br, 28·7%), was converted into the cyano-ester (b. p. 180°/10 mm.) by digestion for 2 hours with an alcoholic solution of potassium cyanide. On hydrolysis, the cyano-ester gave an excellent yield of decane-1 : 10-dicarboxylic acid: this is a more convenient method than that described by Walker and Lumsden (*loc. cit.*) for the preparation of this acid.

Methyl Hydrogen Decane-1 : 10-*dicarboxylate.*—Methyl decane-1 : 10-dicarboxylate, b. p. 170°/10 mm. (Found: C, 65·5; H, 10·0. Calc.: C, 65·1; H, 10·1%) (compare Chuit, *Helv. Chim. Acta*, 1926, **9**, 264), was converted into the hydrogen ester by the method of Grün and Wirth (*loc. cit.*, p. 2215) or by partial hydrolysis with cold alkali. The yield was in both reactions poor. The dibasic acid and the hydrogen ester were separated by treatment with light petroleum, in which the former was very sparingly soluble. *Methyl hydrogen decane*-1 : 10-*dicarboxylate* crystallised from methyl alcohol in prisms, m. p. 51° (Found: C, 63·5; H, 10·0. $C_{13}H_{24}O_4$ requires C, 63·9; H, 9·8%).

11-*Hydroxydodecoic Acid.*—To a mechanically stirred suspension of finely divided potassium methyl decane-1 : 10-dicarboxylate (dried over phosphoric oxide) in boiling absolute alcohol (10—12 parts), sodium (4 times the theoretical quantity) was added as rapidly as possible. After 1 hour, dilute alcohol and water were added and the mixture was heated to hydrolyse the ester. The excess of alcohol was removed with steam, and hydrochloric acid added until the solution was faintly alkaline. After extraction with ether to remove neutral reduction products, magnesium sulphate was added; the magnesium salt of the hydroxy-acid was then precipitated. This was collected and decomposed with hydrochloric acid and the hydroxy-acid obtained was converted once more

the magnesium salt. The acid now regenerated from the magnesium salt still contained an appreciable quantity of the dibasic acid which could not be readily separated by crystallisation. The crude acid was therefore boiled with acetyl chloride, the excess of acetyl chloride removed on the water-bath, and the mixture of 11-acetoxydodecoic acid and decane-1 : 10-dicarboxylic acid separated by treatment with light petroleum, in which the former was readily soluble. The acetylated acid was a wax which did not lend itself to purification. It was hydrolysed with alkali and the *hydroxy-acid* was repeatedly crystallised from light petroleum (b. p. 60—80°) and finally from dilute methyl alcohol; it was then obtained in needles, m. p. 78—79° (Found: C, 66·4; H, 10·9. $C_{12}H_{24}O_3$ requires C, 66·7; H, 11·1%).

The *magnesium* salt, which was very sparingly soluble in water, was an amorphous, white solid (Found: Mg, 5·0. $C_{24}H_{46}O_6Mg$ requires Mg, 5·3%). The methyl ester had b. p. 160°/7 mm. and the anilide crystallised from light petroleum in small prisms, m. p. 87°.

Methyl 11-*Bromododecoate*.—The hydroxy-acid, dissolved in four parts of methyl alcohol, was saturated with hydrogen bromide and after digestion on the water-bath for 3 hours the methyl alcohol was removed in a current of hydrogen bromide. The residue, which crystallised, was dissolved in ether, and the ethereal solution was washed with sodium carbonate solution to remove any acid present, dried, and evaporated. The *bromo-ester* crystallised from methyl alcohol in fatty needles, m. p. about 50°, which was not altered by recrystallisation. Analysis showed the ester to be still somewhat impure (Found: Br, 23·3. $C_{13}H_{25}O_2Br$ requires Br, 27·3%).

Decinene.—Into a suspension of sodamide (from 5 g. of sodium) in liquid ammonia (Hess and Munderloh, *Ber.*, 1918, **51**, 377), acetylene was passed until complete conversion into sodium acetylide had taken place, the temperature being maintained at −60° to −45° by means of liquid air. Octyl iodide (50 g.) having been added, the mixture was allowed gradually to attain room temperature, the ammonia evaporating. After 12 hours, the temperature was maintained at 180° for 8—10 hours. Water was added to the cooled mixture, and the decinene separated by distillation in steam. The hydrocarbon was washed with dilute sulphuric acid to remove basic impurities and distilled; the greater portion passed over at 175—180°/685 mm. ($d_{30}^{30°}$ 0·799, $n_D^{30°}$ 1·44) and was sufficiently pure for conversion into the sodium derivative.

Condensation of Sodiodecinene and Methyl 11-*Bromododecoate*.—To finely divided sodium (0·25 g.), in an atmosphere of hydrogen, decinene (3 g.) was gradually added, the formation of the sodium

compound being hastened by gentle heating. After the addition of the bromo-ester (3·4 g.) in xylene the mixture was heated at 160° for 8 hours. Water was added to the cooled solution, and the xylene and the excess of decinene were removed in steam; the residual oil was dissolved in ether, the ethereal solution washed with sodium carbonate solution, and the solvent evaporated. The thick, oily residue was hydrolysed with methyl-alcoholic potassium hydroxide; the acid, isolated in the usual manner, partly crystallised on keeping. After draining on porous porcelain, it was recrystallised from methyl alcohol, behenolic acid being obtained in glistening needles, m. p. 57°. It was carefully compared with a specimen of behenolic acid prepared from erucic acid, and a mixture of the two acids had m. p. 56·8—57° (Found: C, 78·3; H, 11·6. Calc.: C, 78·5; H, 11·9%). The barium salt also was analysed (Found: Ba, 17·2. Calc.: Ba, 17·0%).

One of us (J. L. S.) wishes to thank Professor C. S. Gibson, O.B.E., for the provision of facilities in his laboratory for carrying out some of the experiments detailed above.

[*Received, August 27th*, 1928.]

CCCLIV.—*Polysaccharides. Part II. The Acetylation and Methylation of Starch.*

By WALTER NORMAN HAWORTH, EDMUND LANGLEY HIRST, and JOHN IVOR WEBB.

EXPERIMENTS have been instituted to render more accessible and to characterise the acetyl and methyl derivatives of starch. In the present work purified potato starch has been employed. Hitherto the yields of both triacetyl and trimethyl starch do not appear to have been satisfactory.

Since Schützenberger's original experiments (*Compt. rend.*, 1865, **61**, 485; 1869, **68**, 814) many investigators have attempted to prepare triacetyl starch. If unmodified starch be employed, the transformation is generally held to be difficult and uncertain, and the small yields lead to serious doubt whether the product is an acetyl derivative of the unchanged starch or is derived from a portion only of polysaccharide which has been segregated during the process of acetylation.

More success has attended the acetylation of a starch which has been subjected to various preliminary treatments. Soluble starch,

for example, has been converted into the triacetyl derivative (Pregl, *Monatsh.*, 1901, **22**, 1049); and the acetylation of the separated amylose constituent of potato starch may readily be effected in the presence of pyridine (Bergmann and Knehe, *Annalen*, 1927, **452**, 141). Such processes, however, not only involve considerable loss during the initial treatment of the polysaccharide, but in many cases suffer also from the disadvantage that the relationship between the original starch and the final product is by no means clear.

We have endeavoured, therefore, to obtain an acetylated derivative of starch in the maximum possible yield and under the simplest experimental conditions. In this way, we consider, information respecting the acetylation of the whole of the starch may be gained, and the properties of the starch acetate may then be compared with those of the known acetylated products isolated by less direct methods and in inferior yield.

Preliminary experiments conducted by the methods of E. Peiser (*Z. physiol. Chem.*, 1926, **161**, 210) failed to give, even in small yield, the acetylated starch of high specific rotation claimed to have been obtained by that author (compare also Pringsheim and Meyersohn, *ibid.*, 1928, **173**, 211). We are in agreement, however, with Peiser that the preliminary precipitation of starch from starch paste by alcohol yields a product which is much more susceptible to acetylation than the original starch, from which it appears to differ only in being more finely divided as the result of the bursting of the granules; *e.g.*, it retains unimpaired the properties of acquiring a deep blue colour on treatment with iodine and of readily giving a paste. Whereas Bergmann and Knehe (*loc. cit.*) conducted the acetylation of separated amylose in the presence of pyridine, we have employed traces of sulphur dioxide and chlorine as catalysts, and we have obtained from precipitated starch a triacetyl derivative in a yield of 96% of the theoretical, based on the weight of the original unmodified starch. Our product is compared below with Bergmann and Knehe's triacetyl amylose :

	Triacetyl starch.	Triacetyl amylose.	Calc.
$[\alpha]_D$ (in chloroform) ...	+170° at 20°	+176° at 16°	—
C, %	49·8	50·0	50·0
H, %	5·8	5·7	5·6
CH_3·CO, %	44·4	44·6	44·8

The triacetyl starch differed little, if at all, in its properties from the product of Bergmann and Knehe. It gave on deacetylation a regenerated starch having all the properties of the regenerated amylose of those authors, being soluble in water and giving the characteristic blue colour with iodine. Both in the precipitated starch and in the triacetyl derivative the presence of traces of

phosphoric acid residues was detected. The deacetylation process almost necessarily involves the scission of the phosphoric ester linkages, and according to the views of Samec and Mayer (*Kolloid-chem. Beih.*, 1921, **13**, 284) on the relationship between amylose and amylopectin the loss of the phosphoric residues must result in the formation of a starch which is incapable of producing a paste with water. This we found to be the case with our regenerated polysaccharide, and the present results have therefore a bearing on the relationship of amylose to amylopectin. It appears that potato starch reacts chemically to the extent of 96% at least as if it were amylose, and our experiments tend to confirm the views of Samec and Mayer. This question will be dealt with in greater detail in a further communication.

Experiments on the methylation of starch have been described by several authors, including Karrer (*Helv. Chim. Acta*, 1920, **3**, 620) and Irvine and Macdonald (J., 1926, 1502). The method adopted by these authors was to act on the original starch with methyl sulphate and alkali and in each case the yield of methylated starch was small, Irvine and Macdonald, *e.g.*, obtaining from 24 methylation treatments a yield of 25% of trimethyl starch. We have obtained, after only six methylations, 89% of the theoretical yield of trimethyl starch by taking advantage of the solubility of triacetyl starch in acetone. The addition of methyl sulphate and dilute alkali to such a solution introduced in one operation 36% of methoxyl, and a progressive increase of the methoxyl content was obtained on each subsequent methylation.

The product appears to be identical with the material described by Irvine and Macdonald, who operated with both rice and potato starch. Hydrolysis of the trimethyl starch with 2% hydrogen chloride in methyl alcohol yielded 80% of pure trimethyl methylglucoside and 8% of a mixture of the latter with dimethyl methylglucoside, leaving a residue of 6% which was not hydrolysed. Hydrolysis of the trimethyl methylglucoside gave crystalline 2 : 3 : 6-trimethyl glucose (yield, 85%) and there can therefore be no doubt that nearly the whole of the potato starch gives rise on methylation and hydrolysis to 2 : 3 : 6-trimethyl glucose.

This conclusion has considerable significance in showing that the mode of linking of the glucose units in potato starch leaves three exposed hydroxyl groups at analogous positions to those which have been determined in the case of cellulose. The specific rotations of trimethyl starch (+ 208°) and trimethyl cellulose (— 18°) are, however, widely different.

By dispensing with the use of acetone as solvent for the triacetyl starch during the methylation, we have prepared a dimethyl starch

(yield, 80% of the theoretical) having $[\alpha]_D + 143°$ in chloroform and OMe, 31·8%. This again appeared to be similar to the dimethyl starch described by Irvine and Macdonald. We were unable, however, with our product to confirm the observation of these authors that this is a homogeneous substance yielding on hydrolysis only dimethyl glucose. Our product gave on hydrolysis a mixture of trimethyl, dimethyl, and monomethyl glucose. The trimethyl glucose was present to the extent of about 20%. The results indicate that all the hydroxyl groups are exposed to simultaneous attack by the methylating agents. In this respect there would appear to be no well-marked difference between the phenomena observed in the methylation of starch and of cellulose. The problem is rather one of obtaining the polysaccharide initially in a suitable condition for combination with the methylating agent. In the present case we have found that after three methylation treatments the starch has acquired a methoxyl content of 40% or more; and similarly with cellulose, Freudenberg and Braun (*Annalen*, 1928, **460**, 288) have observed that the introduction of 42% methoxyl content can be accomplished by two treatments with methyl sulphate if the cellulose fibres used are diminished to 2—4 mm. in length. In the earliest experiments of Denham and Woodhouse (J., 1914, **105**, 2363) a methylated cellulose of about 25% methoxyl content gave an appreciable proportion of trimethyl glucose on hydrolysis. The increase in the methoxyl content of starch from 38 to 44% proceeds just as easily and regularly as from 34 to 38% (contrast Irvine and Macdonald). We are doubful, therefore, whether the claim can be substantiated that seven out of nine hydroxyl positions in starch undergo preferential methylation. If maltose is preformed in starch, then the polysaccharide is composed of glucopyranose units joined in positions 1:4. The alternative hypothesis is that maltose is a reversion product and that starch is composed of glucofuranose units linked in positions 1:5. These opposing views will be the subject of subsequent work.

EXPERIMENTAL.

Acetylation of Starch.—The starch used in these experiments was the purest commercial potato starch (Prime starch), the properties of which corresponded in all respects with those ascribed in the literature to pure potato starch. It contained 18% of water.

It was prepared for acetylation in the following manner. The starch (20 g.) was stirred in water (600 c.c.) on the water-bath until it formed a paste. After 30 minutes the heating was discontinued and the starch was precipitated by the addition of alcohol to the warm paste. The supernatant liquor was decanted from the white

curdy mass which soon settled, and the starch was ground in a mortar in the presence of alcohol. It was then washed with alcohol and ether and dried in a vacuum desiccator (yield, quantitative). This process resulted in the bursting of the granules of the original starch but in general respects appeared to be without effect on its properties. The ash content (0·3%, by incineration), the paste-forming capacity, the blue iodine colour reaction, and the absence of reducing power were all reproduced in the prepared starch.

Attempts to acetylate potato starch by the usual methods revealed many unsatisfactory features, but the following process, which is a modification of Barnett's method (*J. Soc. Chem. Ind.*, 1921, **40**, 8T) for the acetylation of cellulose, was found to be eminently suitable for the routine preparation of the triacetate. Finely powdered starch (prepared in the above manner) was treated with six times its weight of glacial acetic acid through which chlorine had been bubbled for a few seconds. The mixture was stirred for 30 minutes at 20°. Acetic anhydride (20 parts by weight), containing an amount of sulphur dioxide equivalent to that of the chlorine in the acetic acid, was then added and the mixture was stirred at room temperature for 60 minutes. The temperature was then raised to 55° and stirring was continued until a clear solution was obtained (about 4 hours). The clear solution was poured into a large excess of water, and the resulting white powder was washed for some 2 days with changes of water and, when free from acid, successively with dilute alcohol, alcohol, and ether; it was then dried for twenty-four hours in a vacuum (yield, 96·5% of the theoretical). This material contained neither chlorine nor sulphur. It was a white impalpable powder, without action on boiling Fehling's solution, insoluble in ether, alcohol or water, but readily soluble in chloroform and in acetone. The acetate could be reprecipitated unchanged from its solutions in the last two solvents by the addition respectively of alcohol and water. When the acetate was treated with aqueous or alcoholic sodium hydroxide solution, the regenerated starch possessed all the properties of Bergmann's regenerated amylose. Hydrolysis of the acetate by the method of Bergmann and Knehe (*loc. cit.*) gave a white powder, soluble in cold water, $[\alpha]_D^{17°} + 186^b$ ($c = 1·0$). This gave a blue colour with iodine, but did not form a paste with hot water. For the starch acetate the following data were observed: $[\alpha]_{5461}^{20°} + 197°$ in chloroform ($c = 1·0$); $[\alpha]_D^{20°} + 170°$ in chloroform ($c = 1·0$). The air-dry acetate contained 2·2% of moisture. Acetyl estimations were carried out by treating a weighed quantity with an excess of $N/2$-alcoholic sodium hydroxide for 3 hours at 50°,

frequent shaking (Found : C, 49·8; H, 5·8; CH_3·CO, 44·4; P, as P_2O_5, 0·05. $C_{12}H_{16}O_8$ requires C, 50·0; H, 5·55; CH_3·CO, 44·8%).

Acetylation of the prepared starch may be effected at temperatures higher or lower than the 55° mentioned, without affecting in any way the chemical properties or the specific rotation of the starch acetate. Too low a temperature, however, involves prolonged treatment. The principal difference between the various samples of acetate obtained at different temperatures appeared to lie in the greater viscosity of the acetate solutions obtained at lower temperatures.

It is to be noted that careful preparation and drying of the "prepared" starch are essential. Certain specimens of prepared starch which had been heated at 80° to complete the drying process were found to acetylate slowly and imperfectly, the retardation being due apparently to alteration of surface conditions produced by heat.

For comparison, acetylations were also carried out on the original starch (before preparation), (*a*) chlorine and sulphur dioxide, as above, and (*b*) sulphuric acid being used as catalysts. In (*a*) it was found impossible to effect complete solution of the starch even after 12 hours at 65° with high concentrations of catalyst. After removal of the undissolved starch by filtration through glass wool the acetylated starch was isolated in the manner already described. The product was essentially similar to that from prepared starch but had a lower specific rotation, $[\alpha]_D$ + 154° in chloroform (c = 1·0). The yield (15% of the theoretical) was very inferior to that of the first method.

In case (*b*) 10 g. of starch and 60 c.c. of acetic anhydride containing 12 drops of sulphuric acid were heated at 55° for 8 hours. The brown liquid was filtered through glass wool, and the product isolated as before. The resulting acetate showed $[\alpha]_D$ + 169° in chloroform (c = 1·0) and appeared to be identical with the material obtained from the prepared starch. The yield, however, was small (10—15%), much of the starch either decomposing or not undergoing acetylation.

Methylation of Potato Starch.—Preliminary experiments, following the methods of Irvine and Macdonald (*loc. cit.*), confirmed the grave manipulative difficulties encountered in the direct methylation of starch. When, however, a method of simultaneous deacetylation and methylation was used, these difficulties almost entirely disappeared. This was peculiarly the case when the operations were conducted in acetone solution. If the following procedure is adopted, methylation of starch becomes sufficiently rapid and convenient to render methylated starch the most suitable intermediate substance for the preparation of 2 : 3 : 6-trimethyl glucose.

(a) *Methylation in presence of water only.* Powdered starch triacetate (20 g.) was treated with 30% sodium hydroxide solution (224 c.c.) and methyl sulphate (80 c.c.), added gradually and simultaneously with vigorous mechanical stirring. The temperature was maintained at 50° for 1¼ hours and thereafter at 70° for a further 1¼ hours until the whole of the reagents had been added, care being taken to avoid acidity at any stage. After being heated for 30 minutes at 100°, the solution was cooled, rendered almost neutral by addition of 30% sulphuric acid, and filtered. The solid residue was extracted with boiling chloroform. The slightly alkaline aqueous portion was treated with excess of carbon dioxide and evaporated to dryness in the presence of barium carbonate, and the solid residue extracted with chloroform. The united chloroform extracts yielded (when evaporated) a white flaky solid, which was slightly soluble in water or chloroform and had a methoxyl content only slightly lower than that required by a dimethyl starch. Yield, 80% of the theoretical for dimethyl starch. $[\alpha]_D$ + 143° in chloroform ($c = 1{\cdot}0$) (Found: OMe, 31·8. Dimethyl starch requires OMe, 32·7%).

Hydrolysis of dimethyl starch. The methylated starch (4·0 g.) was dissolved in methyl alcohol (50 c.c.) containing 2% of hydrogen chloride and the solution was boiled for 24 hours. The acid was neutralised by addition of lead carbonate, and the product isolated in the usual way. It was a viscous syrup (4·55 g.) which, on distillation, gave (I) 0·9 g., b. p. 110—117°/0·05 mm., $n_D^{16°}$ 1·4611 (Found: OMe, 47·7%); (II) 1·45 g., b. p. 117—130°/0·04 mm., $n_D^{16°}$ 1·4670 (Found: OMe, 41·5%); (III) 1·48 g., b. p. 130—180°/0·03 mm., $n_D^{16°}$ 1·4800 (Found: OMe, 37·2%); (IV) still residue, 0·6 g. Dimethyl methylglucoside and trimethyl methylglucoside require respectively OMe 41·9% and 52·6%. The distillates were glucosidic in character; (I) appeared to consist mainly of trimethyl methylglucoside, and (II) and (III) mainly of dimethyl methylglucoside admixed with some monomethyl methylglucoside. This diagnosis was confirmed in the case of (I) by hydrolysing it with boiling 5% aqueous hydrochloric acid for 4 hours. The acid was neutralised with barium carbonate, the neutral solution evaporated to dryness at 50°/15 mm., and the product of hydrolysis extracted from the solid residue by boiling ether. Removal of the ether left a syrup which crystallised almost completely (yield, 80%). Recrystallisation from ether removed some adhering gum and gave in good yield 2 : 3 : 6-trimethyl glucose, m. p. 117—118°; mixed m. p. with a specimen of 2 : 4 : 6-trimethyl glucose of m. p. 124°, 90—96°. No tetramethyl glucose was present.

Further methylations by the same method gave a pro-

gressive increase in the methoxyl content. This applied also to the simultaneous deacetylation and methylation of the acetylated methylated starch obtained by heating dimethyl starch with acetic anhydride and fused sodium acetate at 100° for 1½ hours (compare Irvine and Macdonald, *loc. cit.*). Methylation by means of Purdie's reagents was ineffective and was known to lead to changes in the nature of the methylated starch.

(b) *Methylation with acetone as solvent.* The process (a) yielded a dimethyl starch readily and in good yield, but constituted no improvement on known methods for proceeding from dimethyl starch to the fully substituted derivative. The following method gives in one operation a methylated starch with a methoxyl content of 36%, greatly reduces the manipulative difficulties, and facilitates the preparation of trimethyl starch in almost quantitative yield. It consists essentially in the simultaneous deacetylation and methylation of starch triacetate dissolved in acetone in a large flask provided with a reflux condenser, through which the spindle of the stirrer is passed. Efficient stirring is necessary. The methoxyl content of the product may be varied by employing a smaller quantity of acetone and in this way methylated starches containing from 28% to 36% OMe have been obtained.

Preparation of methylated starch (OMe, 36%). Powdered starch triacetate (25 g.) was dissolved in acetone (250 c.c.) and treated with 30% sodium hydroxide solution (280 c.c.) and methyl sulphate (100 c.c.). The methylating reagents were added (with the usual precautions) in ten equal portions at intervals of 10 minutes, the temperature being maintained at 56°. After being heated for 30 minutes at 100°, during which the acetone was allowed to evaporate, the mixture was almost neutralised with sulphuric acid, treated with excess of carbon dioxide, and filtered. The aqueous portion was extracted four times with chloroform; * the solid was extracted with boiling chloroform. The combined extracts gave on evaporation a light yellow, glassy solid (16·8 g.; 96% of the theoretical). Further purification was effected by dissolving it in a little chloroform and boiling with excess of ether. This yielded a white impalpable powder which was dried at 100°/15 mm. The loss during this treatment was inappreciable. The dry substance showed $[\alpha]_D$ + 170° in chloroform. Ash (mainly sodium sulphate), 1·6%

* When methylated starches of methoxyl content 34% or more are being dealt with, the chloroform separates readily from the aqueous layer. Below 34% an intractable emulsion usually forms and more tedious methods have to be adopted (see above). With increasing methoxyl content manipulative difficulties of this kind progressively diminish.

(Found: C, 50·8; H, 7·7; OMe, 36·0. Calc. for methylated starch: C, 51·2; H, 7·6; OMe, 36·0%).

Two more methylations under similar conditions raised the methoxyl content by 4%. After three further methylations (being six in all) a product corresponding very closely to trimethyl starch was obtained. The final product was purified by dissolving it in a little chloroform and boiling the solution with excess of light petroleum. The crisp white powder obtained was treated again with light petroleum, separated by filtration, and dried in a vacuum (Found: OMe, 44·0; ash, 0·04%). The loss in yield on each methylation was 0·1 g., and the final yield of methylated starch from starch triacetate was thus 92% of the theoretical. This represents a yield of 89·4% of the theoretical from the original starch.

No advantage could be gained by introducing an acetylation process after the first methylation, the solubility of the methylated starch in acetone being apparently the decisive factor in facilitating the etherification. For instance, in one experiment the product from the first treatment of starch triacetate in acetone solution (yield, 16·4 g. from 25·0 g. Found: C, 50·4; H, 7·8; OMe, 34·4; ash, 0·9%) was acetylated by heating it with 8 parts of acetic anhydride and 1 part of fused sodium acetate for 1½ hours at 100°. The mixture was then poured into an excess of cold water, the acid neutralised with sodium bicarbonate, and the product extracted from the solution by chloroform (yield, 10 g. from 10 g. Found: CH_3·CO, 12; OMe, 30·6%). Simultaneous deacetylation and methylation in acetone, followed by a further acetylation and combined deacetylation and methylation, raised the methoxyl content to 36·4%. Four successive methylations in acetone solution then gave trimethyl starch (Found: OMe, 45%).

Trimethyl Starch and its Hydrolysis.—The methylated starch finally obtained was a white powder, m. p. 145° with previous softening, $[\alpha]_D$ + 208° in chloroform (c = 1·0), which appeared to be identical with the material described by Irvine and Macdonald (*loc. cit.*) (Found: C, 52·4; H, 7·9; OMe, 44·0; * ash, 0·04. Calc. for $C_9H_{16}O_5$: C, 52·9; H, 7·8; OMe, 45·5%). When boiled for 24 hours with methyl alcohol containing 2% of hydrogen chloride, it gave (*a*) pure trimethyl methylglucoside, b. p. 95—97°/0·02 mm., $n_D^{24°}$ 1·4550 (yield, 80%) (Found: OMe, 51·8. Calc.: OMe, 52·6%); (*b*) a mixture of trimethyl methylglucoside and dimethyl methylglucoside having $n_D^{24°}$ 1·4630, OMe 44% (yield, 8%); (*c*) a small

* As in the case of cellulose, the final 1% of methoxyl can be introduced only with great difficulty. In the present experiments methylation has not been carried beyond the stage 44—45%.

quantity of solid which appeared to be unhydrolysed material (yield, 6%). Fraction (*b*) corresponded to the small amount of dimethyl starch in the original material, the presence of which was indicated by the slight deficiency in the OMe value. Hydrolysis of (*a*) with boiling 5% aqueous hydrochloric acid gave only 2 : 3 : 6-trimethyl glucose (yield, 85%), which, after one recrystallisation, had m. p. 117° alone or when mixed with an authentic specimen of the same m. p. Tetramethyl glucose was definitely absent.

The authors express thanks to the Chemical Society for a grant to one of them (J. I. W.) from the Research Fund, which has partly defrayed the cost of this investigation.

CCCLV.—*Polysaccharides. Part III. The Molecular Complexity of Inulin.*

By HARRY DUGALD KEITH DREW and WALTER NORMAN HAWORTH.

IT is now generally accepted that inulin is composed entirely of anhydro-γ-fructose or -fructofuranose units associated with water molecules, the relative proportion of water depending upon the method of drying. For instance, Tanret (*Bull. Soc. chim.*, 1893, **9**, 200, 227, 622) regards inulin as $(C_6H_{10}O_5)_6,H_2O$ at 130° and as $(C_6H_{10}O_5)_6,7H_2O$ in moist air at the ordinary temperature. Other attempts to determine the number of anhydrofructose units in the inulin molecule have given very conflicting results. Karrer and Lang (*Helv. Chim. Acta*, 1921, **4**, 249), from a determination of the molecular weight of trimethyl inulin in freezing phenol, find nine anhydrofructose units, in agreement with the molecular weight of triacetyl inulin in naphthalene, glacial acetic acid, and phenol, as determined by Pringsheim, Aronowsky, and Lassmann (*Ber.*, 1921, **54**, 1281; 1922, **55**, 1409). Bergmann and Knehe (*Annalen*, 1926, **449**, 302; *Ber.*, 1926, **59**, 2079) find only two anhydrofructose units in acetyl inulin prepared in the presence of pyridine. Again, Hess and Stahn (*Annalen*, 1927, **455**, 104) find that triacetyl inulin as prepared by Bergmann and Knehe has in air-free acetic acid a (cryoscopically determined) molecular weight which varies with time from that corresponding with the presence of one anhydrofructose unit up to infinity. Later work of Pringsheim and Fellner (*Annalen*, 1928, **462**, 231) indicates that the molecular weight of "inulin," regenerated from inulin acetate heated at various temperatures in presence of tetrahydronaphthalene, is variable according

to the temperature of the heating, two, three, or four anhydrofructose units being present in the molecule. Direct determinations of the molecular weight of inulin in water are stated by these authors to agree in indicating that seven anhydrofructose units are present in the molecule.

It is clear that derivatives of inulin (such as the acetyl and methyl compounds) can throw no light on the complexity of inulin itself until it is demonstrated that these derivatives are simply related to the carbohydrate; and, although it has been alleged that inulin may be regenerated from the triacetyl compound, no definite proof of this statement has yet been given. Indeed, it has by no means been shown that inulin consists of uniform molecules.

Assuming that inulin consists of anhydrofructose units, these may be united either by residual affinities, in which case the structural units are retained as such in the complex, or by ordinary valencies, when the fructofuranose units are linked in chain formation. If the latter be true, as seems probable at present (compare Haworth and Learner, this vol., p. 619), the chain of γ-fructose (fructofuranose) units in the inulin molecule may be either open or closed to a ring. If it be an open chain, aqueous solutions of inulin should show slight reducing properties, due to the terminal reducing groups of the chains; if the ends of the chains be joined to give a ring, reduction may not be made manifest.

It has generally been held that pure inulin has no reducing action on hot Fehling's solution, but we have not yet succeeded in obtaining a sample of inulin which did not show slight and progressive reducing action on the boiling reagent. Such action may be due initially to the presence of open-chain molecules augmented subsequently by hydrolysis, or it may be due to the hydrolysis alone.

The inulin of commerce, derived from dahlia tubers, contains a considerable amount of ash consisting of mineral bases and salts, part of which is soluble in water after ignition, yielding an alkaline solution. The main bulk of this mineral matter may be separated from the inulin by the following simple process: The inulin is dissolved rapidly in hot water, and the solution boiled for a few minutes with a little active charcoal which has been carefully freed from soluble salts; it is then filtered, and the process is repeated unless the filtrate is colourless and water-clear. The bulk of the inulin is then frozen out, redissolved, boiled momentarily with a little more charcoal, again frozen out, then redissolved and precipitated by a large excess of alcohol, washed with alcohol, and dried. The white powder obtained has no reducing action

Fehling's solution during 24 hours in the cold, but shows slight reduction on boiling or even on keeping at 50°. It contains about 1 part in 1000 parts of ash, as determined by heating in a platinum boat with or without sulphuric acid (*e.g.*, 14·139 mg. gave 0·014 mg. of ash). The ash appears to consist mainly of silica. The water-content was determined by heating during 2¾ hours at 75° to 110° in a stream of dry air at low pressure; the loss of water was 10% of the original weight of the sample (*e.g.*, 5·571 mg. lost 0·553 mg. of water). The resulting powder, which was extremely hygroscopic, gave on analysis: C, 44·3; H, 6·5 [$(C_6H_{10}O_5)_x$ requires C, 44·4; H, 6·2%].

The determination of the molecular weight, or average molecular weight, of "ash-free" inulin in boiling water was now attempted. The initial assumption was necessarily made that inulin is unaltered in molecular structure by solution in boiling water. That an alteration, at least in physical structure, does occur, however, is evident from the abrupt change in the solubility of inulin in water between 80° and 100°: 100 c.c. of solution at 14° contain 0·02 g. of inulin; at 80°, 4·0 g.; and at 100°, no less than 36·5 g. This view receives some support, also, from our own observation that the position of the decomposition range on the temperature scale varies markedly with the amount of water retained by different samples of inulin; *e.g.*, the decomposition range is situated above 200° for specimens of "glassy" inulin rich in water, but is much lower for drier powdery samples. Inulin, as would be expected, never shows a true melting point. The molecular state of inulin in boiling water would nevertheless be of interest, and it is unfortunate that another complication enters into the determination. The apparent molecular weight of inulin in boiling water shows continuous diminution over a considerable period of time, and we have found that the reducing power of the solution rises as the molecular weight decreases, and that the action is not completely, if at all, reversed in the cold. These facts point distinctly towards the occurrence of hydrolysis.

The hydrolysis probably depends upon the presence of minute traces of acid electrolytes, since pellets made from the same bulk sample of inulin on different occasions did not always show the same initial molecular weights nor the same rate of hydrolysis, and pellets which had been handled with the fingers seemed to hydrolyse relatively rapidly. Contamination by the surface of the pellet-press was difficult to avoid and may partly account for the discrepancies. The following are typical examples of the results, W indicating the weight of water, w that of the water-free inulin, and the times being reckoned from that of the addition of the inulin (the pellets were seen to dissolve completely in from 1 to 2 minutes):

I.			II.			III.		
W, 14·7 g.; *w*, 0·8748 g.			*W*, 14·95 g.; *w*, 1·0701 g.			*W*, 14·35 g.; *w*, 1·2542 g.		
Mins.	Rise of b. p.	*M*.	Mins.	Rise of b. p.	*M*.	Mins.	Rise of b. p.	*M*.
3	0·008°	3870	5	0·012°	3100	4	0·011°	4130
7	0·011	2810	8	0·013	2860	7	0·014	3250
10	0·017	1820	23	0·020	1860	13	0·017	2670
17	0·024	1290	48	0·025	1490	28	0·022	2070
						39	0·025	1820

The times of observation were extended, in some cases, beyond those shown, and it was found that the molecular weight continued to fall, even below 900. It is evident that no exact significance attaches to the figures, nevertheless they appear to us to indicate that the initial molecular weight of inulin in boiling water is not less than 3200 or 3600; *i.e.*, the inulin molecule contains not fewer than 20 or 24 anhydrofructose units. Initial experiments showed that a perfectly steady indication of the boiling point of the water could be obtained by placing clean fragments of garnets, mixed with pieces of platinum foil, in the boiling-bulb (provided with a thick piece of platinum wire sealed into the lower extremity), so that the height of the column of garnets, which terminated just below the bulb of the thermometer, bore a certain ratio to that of the column of water above it. Four minutes were allowed for the re-attainment of the true boiling point after the addition of the pellets, this time having been determined roughly by other measurements with the apparatus.

It will be clear that the molecular weight of inulin may be much higher than that indicated by these experiments, both because the initial changes of temperature are necessarily very small and because the initial effect of traces of electrolytes may be relatively very great. We hope to investigate this aspect of the matter in further experiments.

It seems clear that the results of Pringsheim and his co-workers (*loc. cit.*) can have little significance, unless he has succeeded in obtaining a specimen of inulin that is stable to boiling water. In any case, his procedure for the cryoscopic determination of the molecular weight (namely, to make up a solution of inulin in boiling water and then to cool it and determine the freezing point) is inadmissible, and the agreement of his cryoscopic and ebullioscopic results is possibly fortuitous.

It has frequently been stated that inulin shows, on hydrolysis by mineral acids, no intermediate stage between itself and fructose. Certain observations which we have made during the past two years indicate that this view is erroneous; and although our experiments have not resulted in the isolation of demonstrably homogeneous

intermediates, it seems desirable at this stage briefly to indicate their nature.

When a stream of carbon dioxide is passed during about 2 days through an aqueous solution of inulin, the solution being occasionally warmed to redissolve any inulin which has separated, a considerable proportion of the inulin becomes changed to a white powder having a lower range of decomposition on heating than inulin and shows a tendency to effervesce at higher temperatures. The powder differs from inulin, also, in that it is readily soluble in cold water to a water-clear solution which does not foam when shaken. The product, the specific rotation of which in water is rather higher than that shown by inulin, has a greater reducing action towards hot Fehling's solution.

The same effect can be produced by treating an aqueous solution of inulin in an autoclave with carbon dioxide at a pressure of about 230 lb./sq. in. during about 24 hours. Unchanged inulin is filtered off, and the clear solution is precipitated by the addition of an excess of acetone, a product similar to the foregoing being obtained.

The transformation may also be brought about in the dry way at the ordinary temperature. For instance, when inulin powder is kept in a desiccator in which is present a little vaporous ethyl chloroformate, the inulin is gradually changed into a product similar to that already described. The change may take many months; its speed seems to depend upon the proportion of water present in the inulin, very dry inulin requiring a longer period. This behaviour indicates that the change is hydrolytic, and that it is produced by traces of hydrochloric acid generated by the decomposition of the chloroformate in the presence of water.

A sample of inulin powder which has become "infected" in this manner suffers progressive degradation even when the chloroformate vapour is removed; and, if the infection be acute or if the water content of the original inulin be high, the powder may finally change to a yellow syrup which contains much fructose. Inulin may be "infected" without the agency of chlorinated substances; *e.g.*, inulin which has been recovered by precipitation with acetone from aqueous solutions treated with carbon dioxide undergoes the change when kept in a desiccator over phosphoric oxide or calcium chloride. In such cases the change is slow and the final product is a flaky powder apparently free from ordinary fructose.

The change may in most cases be arrested by repeatedly dissolving the sample in water and reprecipitating it by means of acetone. In some cases, however, even this treatment does not prevent the occurrence of slow subsequent change.

Naturally, the method of isolation by precipitation leads to

fractionation of the product, the more soluble products of lower molecular weight remaining in solution. Our attention has been mainly directed towards the water-soluble product (precipitable by acetone) which can usually be obtained in high yield.

We have not succeeded in showing that this product is molecularly homogeneous, but we believe that it approximates to this condition and that it is an open-chain compound, of high molecular weight, containing one or two free reducing groups in the molecule. The following is a description of the product, which may be regarded as analogous to a starch dextrin.

Inulin "lævulin." The substance obtained in the foregoing manner was carefully separated from unchanged inulin and from substances of lower molecular weight by repeated solution in cold water, filtration, and reprecipitation with acetone. The fine white powder so obtained (7 g.) dissolved to a slightly opalescent solution in 75 c.c. of water at 19°; the solution was passed through a streamline filter, which was rinsed with a further 125 c.c. of water. The clear, colourless solution, neutral to litmus and quite free from halogen and methoxyl, was now treated slowly with 300 c.c. of acetone. After 1½ hours, the white, granular precipitate (5 g.) was collected, washed with 100 c.c. of acetone, and kept over phosphoric oxide. The substance melted to a white, opaque paste at about 142°, and the paste became a white froth near 185°. It was dehydrated in a vacuum during 11 hours at 80°, then during 24 hours at 95°, and finally at 120° during 6 hours, the loss of water amounting to about 7·5% (Found: C, 43·8; H, 6·5%). The product contained 1% of ash, which was allowed for in the analysis. A sample dried at 90° in a vacuum had $[\alpha]^{21°}_{5461}$ −45·8° in water ($c = 4·778$) and showed no mutarotation after a month. Other samples showed approximately the same rotation.

Cryoscopic determinations of the molecular weight in water gave results varying between 900 and 1100 for the undried material, and between 1200 and 1600 for the material dried at 90° in a vacuum. Ebullioscopic determinations gave results varying between 1400 and 1800.

It is doubtful whether much significance can be attached to these figures; but it seems possible that the effect of dehydration or of hot water tends to change the product back in the direction of inulin by the relinking of chains opened in the former degradation process.

Another sample of this product, prepared in a similar way, was ash-free, lost 7% of water when dried in a vacuum at 80° during 8 hours, melted to a white paste at about 145° and frothed at a higher temperature (Found: C, 43·5; H, 6·5%). Many other

analyses were carried out on similar products dried under various conditions, the average of these results showing C, 43·3; H, 6·5 (octasaccharide requires C, 43·8; H, 6·2%; *M*, 1314. Hexasaccharide requires C, 43·6; H, 6·3%; *M*, 990). The substance reduces dilute Fehling's solution at 50°, the reduction commencing after a few minutes and being considerable in 10 minutes, whereas inulin under these conditions showed only a trace of reducing action after ½ hour.

Experience has shown that it is important to remove the ash as completely as possible from inulin before investigating the properties of this substance, a consideration which we did not at first closely regard. We intend to repeat our experiments with ash-free inulin if this is attainable. It is possible that inulin is protected from the hydrolysing action of boiling water by the presence of weakly alkaline mineral matter contained among the "ash," and that the removal of ash, either by purification or by neutralisation with traces of acid, permits the onset and continuation of the hydrolysing process which we have described; but it is not yet certain that the hydrolysis of inulin by boiling water is a process identical with the catalytic degradation taking place in the dry way.

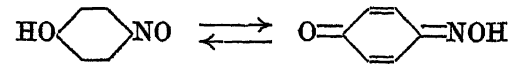
By allowing the transformation of inulin to proceed to different lengths, products of lower decomposition range have been isolated. These are considered to be mixtures of compounds containing shorter chains. The best-defined was a *substance* obtained, by the action of carbon dioxide on aqueous inulin, as a white powder which melted to an opaque paste at 85—86° and effervesced at 120—125°. This was readily soluble in cold water and had $[\alpha]^{20°}_{5461}$ −45·6° in water ($c = 2·28$), the negative rotation slightly increasing with time. A further specimen, of initial m. p. 92—95°, gave C, 42·0; H, 6·8%; *M* (cryoscopic), 520 in water. The substance may be an impure tetra- or tri-saccharide in a partly hydrated condition. It reduced warm Fehling's solution, and also cold aqueous potassium permanganate on standing.

Summary.

It is considered probable that inulin consists of chains of fructofuranose or γ-fructose rings, the molecule containing at least 20 or 24 such rings.

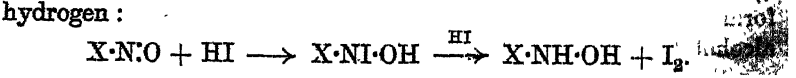
Degradation, by means of carbon dioxide or a trace of hydrogen chloride, consists in the hydrolytic scission of the chains at junctions between the rings, polysaccharides with shorter chains being produced. Dehydration may in certain circumstances tend to regenerate the longer-chain polysaccharides or inulin itself. Complete scission probably leads to the production of γ-fructose, which is

then irreversibly changed to ordinary fructose. The migration of inulin in plant stems may possibly occur through the formation of water-soluble polysaccharides which are subsequently dehydrated to inulin in the tubers.



The authors are indebted to the Chemical Society for a grant to one of them which has partly defrayed the cost of the materials used in this investigation.

UNIVERSITY OF BIRMINGHAM,
EDGBASTON. [*Received, August 21st,* 1928.]



CCCLVI.—*A Contribution to the Chemistry of Nitroso-compounds.*

By JOHN CAMPBELL EARL, FRANK CADWALLADER ELLSWORTH, EDWARD CHARLES SNELL JONES, and JAMES KENNER.

THE remarkable ease with which nitroso-compounds are reduced to hydroxylamino-derivatives by cold dilute hydriodic acid at the ordinary temperature (Earl and Kenner, J., 1927, 2139) has led us to consider the reaction more closely. It is well known that nitroso-chlorides, if not polymerised, are usually oximes, and even in those cases in which a polymeride of the true nitrosochloride is known, *e.g.*, pinol nitrosochloride, it can be changed into the *iso*nitroso-modification. Further, no indication has been found that the reaction is reversible, and, in the case of the oximes themselves, it is only comparatively recently that any evidence of a reversion to the nitroso-form has been obtained (Griffiths and Ingold, J., 1925, **127**, 1698). It is true that the tautomerism of *p*-nitrosophenol involves such a reversal, but this is due to the general inclination of quinonoid compounds to assume the more saturated benzenoid condition:

In these cases the change to the oximino-form is intramolecular, but the same tendency appears in intermolecular reactions. The facility with which *p*-nitrosodimethylaniline is converted into *p*-nitrosophenol by hydrolysis is perhaps the most familiar instance of this kind, and the reduction of nitroso-compounds to hydroxylamines by hydriodic acid is a reaction governed by the same tendency. In our view, it is best formulated as an additive reaction in the first place, followed by displacement of the iodine atom by hydrogen:

The formation of *N*-hydroxyamidines from nitrosobenzene and methyleneanilines (Burkhardt, Lapworth, and Robinson, J., 1925, **127**, 2234) is also to be included under this heading:

$$Ar{\cdot}N{:}O + Ar'{\cdot}N{:}CH_2 \longrightarrow Ar{\cdot}N(OH){\cdot}CH{:}NAr'.$$

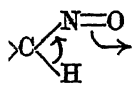
This brief review throws new light on the classical synthesis of glycerol by Piloty and Ruff (*Ber.*, 1897, **30**, 1656). This depends on the elimination of formaldehyde, which occurs when the hydroxylaminobutanetriol (I) is subjected to oxidation by yellow mercuric oxide. Clearly the reaction is only another illustration of the property of the nitroso-group just discussed:

$$\underset{\text{(I.)}}{(CH_2{\cdot}OH)_3C{\cdot}NH{\cdot}OH} \longrightarrow [(CH_2{\cdot}OH)_3C{\cdot}NO] \longrightarrow CH_2O + (CH_2{\cdot}OH)_2C{:}NOH.$$

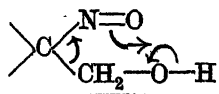
The corresponding nitrobutanetriol (II) is itself stable, but also loses formaldehyde under the influence of alkali (Schmidt and Wilkendorf, *Ber.*, 1919, **52**, 389). Wilkendorf and Trénel (*Ber.*, 1923, **56**, 611) were, however, unable to accomplish the direct elimination of a second molecule of formaldehyde from the nitrobutanetriol. But the foregoing considerations make it clear that this must occur if a nitroso-group be appropriately introduced into the molecule of β-nitropropane-αγ-diol (III).

$$\underset{\text{(II.)}}{(CH_2{\cdot}OH)_3C{\cdot}NO_2} \longrightarrow CH_2O + \underset{\text{(III.)}}{(CH_2{\cdot}OH)_2C{:}NO_2H} \longrightarrow \underset{\text{(IV.)}}{[(CH_2{\cdot}OH)_2C(NO_2){\cdot}NO]} \longrightarrow \underset{\text{(V.)}}{HO{\cdot}CH_2{\cdot}C(NO_2){:}NOH}$$

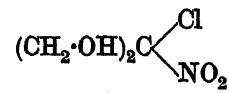
$$\uparrow$$



$$\underset{\text{(VI.)}}{HO{\cdot}CH_2{\cdot}CH_2{\cdot}NO_2}$$



This prediction has been experimentally verified by treatment of the sodium salt of the diol with nitrous acid under precisely those conditions prescribed by V. Meyer and Constam (*Annalen*, 1882, **214**, 328) for the preparation of ethylnitrolic acid from nitroethane. The action of nitrous acid on the cooled aqueous solution of the salt at first causes the production of the characteristic well-known blue colour indicative of the formation of the pseudonitrol (IV), but this almost at once gives place in the alkaline solution to the red colour of the nitrolic acid salt. The formaldehyde produced has been identified by its condensation with β-naphthol, and the β-*hydroxyethylnitrolic acid* (V) has been isolated in the crystalline condition, and its constitution also established by its identity with the product obtained in the usual manner from β-nitroethyl alcohol (VI). Since, however, the sodium salt of β-nitropropane-αγ-diol is obtainable in one operation from nitromethane and formaldehyde (Wilkendorf and Trénel, *loc. cit.*), whereas nitroethyl alcohol has to be prepared from glycolchlorohydrin through the



iodohydrin and, as we found, then requires further purification through its sodium salt for the present purpose, the new reaction is the more convenient method of obtaining the acid. In order to demonstrate the general character of the reaction, we have also shown that ethylnitrolic acid is produced by the action of nitrous acid on the sodium salt of β-nitropropanol :

$$CH_3{\cdot}C(CH_2{\cdot}OH){:}NO_2Na \longrightarrow CH_3{\cdot}C(NO_2){:}NOH + CH_2O.$$

These reactions indicate that when the carbon atom next the nitroso-group does not carry a hydrogen atom which would enable the change, indicated in (VII), to the oximino-condition to occur,

(VII.)

(VIII.)

(IX.)

a methylol group can supply the necessary hydrogen atom, as shown by (VIII). In this case the electronic changes induced by the nitroso-group are transmitted through a chain of singly linked atoms. The same applies to the case of the nitrobutanetriol (II) and the fact that β-chloro-β-nitropropane-αγ-diol (IX) suffers elimination of formaldehyde rather than elimination of chlorine (Wilkendorf and Trénel, *loc. cit.*) illustrates the readiness with which such transmission occurs.

A number of other well-known reactions appear to depend on the characteristic of the nitroso-group emphasised above. For instance, the exceptional behaviour of nitrous acid in so readily forming an anhydride can be ascribed to the following reactions :

$$HO{\cdot}N{:}O + H{\cdot}ON{:}O \longrightarrow HO{\cdot}N\langle^{OH}_{ON{:}O} \longrightarrow H_2O + O{:}N{\cdot}O{\cdot}N{:}O.$$

Similarly, the almost instantaneous esterification of ethyl alcohol by cold dilute nitrous acid (compare Thiele and Eichwede, *Annalen*, 1900, **311**, 366, footnote) and the course of the well-known reactions between potassium nitrite and potassium hydrogen sulphite (Raschig, *Annalen*, 1887, **241**, 207) are readily understood from this point of view. Again, the interaction of hydriodic acid and nitrous acid would, according to the scheme already suggested for nitroso-compounds in general, lead to the compound (X), which could then

$$\underset{\text{(X.)}}{HO{\cdot}NH{\cdot}OH} + HO{\cdot}N{:}O \longrightarrow HO{\cdot}N(OH){\cdot}N(OH)_2 \longrightarrow 2H_2O + O{:}N{\cdot}N{:}O \downarrow 2NO.$$

react with more nitrous acid in the manner indicated, resulting in the eventual formation of nitric oxide.

Again, nitrous acid probably derives its distinctive value as a reagent for reactive methylene groups from its tendency to form an oximino-derivative (compare Wolff, *Annalen*, 1895, **288**, 10):

$$-\overset{|}{C}H_2 \longrightarrow -\overset{|}{C}H\cdot N(OH)_2 \longrightarrow -\overset{|}{C}{:}NOH + H_2O.$$

It does not seem previously to have been realised that, owing to the correspondence in chemical relationships of the CH group with the nitrogen atom and of the imino-group with the oxygen atom, a close constitutional connexion exists between methyl alcohol, hydroxylamine, and hydrogen peroxide, and, in fact, each undergoes catalytic dehydrogenation by platinum-black. Extending now Wieland's formulation in the cases of methyl alcohol and hydrogen peroxide (*Ber.*, 1921, **54**, 2353) to that of hydroxylamine, we have:

$$H\cdot N\langle^{H}_{OH} \longrightarrow H_2 + HN{:}O.$$

Actually ammonia, water, and nitrous oxide are formed (Tanatar, *Z. physikal. Chem.*, 1902, **40**, 475). Apparently nascent hydrogen and a part of the "nitroxyl" first formed give rise to ammonia, whilst the remainder is converted into nitrous oxide:

$$2HNO \longrightarrow HN(OH)\cdot N{:}O \longrightarrow N{:}N{:}O.$$

This gas is produced quantitatively by oxidation of hydroxylamine with ferric sulphate (Raschig, *Annalen*, 1887, **241**, 188; *Z. anorg. Chem.*, 1904, **17**, 1411) as well as by reduction of nitrous acid (Raschig, *Z. anorg. Chem.*, 1904, **17**, 1398) and, particularly interesting for the present discussion, by hydrolysis of nitrososulphonic acid (compare Abegg, "Handbuch der Anorganischen Chemie," 3, iii, 153):

$$O{:}N\cdot SO_3H + H_2O \longrightarrow H_2SO_4 + HN{:}O.$$

In the previous paper (Earl and Kenner, *loc. cit.*) it was pointed out that in spite of the well-recognised analogy between the carbonyl and the nitroso-group, the former does not undergo reduction with cold dilute hydriodic acid. This corresponds with the greater stability of the ketonic than the enolic form of simple carbonyl compounds, and the foregoing considerations would therefore lead

(XI.) $>C\langle^{CH_2\cdot OH}_{CHO}$ $(CH_2\cdot OH)_3C\cdot CHO$ (XII.)

(XIII.) $CH_3\cdot C(CH_2\cdot OH)_2\cdot CHO$ $CHMe_2\cdot C(CH_2\cdot OH)_2\cdot CHO$ (XIV.)

us to anticipate that the grouping (XI) would be stable and not lose formaldehyde under ordinary conditions. Accordingly penta-

erythrose (XII) (McLeod, *Amer. Chem. J.*, 1907, **37**, 20), αα-dimethylolpropanal (XIII) (Koch and Zerner, *Monatsh.*, 1901, **22**, 448), and αα-dimethylol-β-methylbutanal (XIV) (Lichtenstern, *ibid.*, 1905, **26**, 499) have been described and satisfactorily identified. On the other hand, Rave and Tollens showed that when pentaerythritol is oxidised by dilute nitric acid one of the products is an aldehyde of the empirical formula $C_4H_6O_3$, to which they assigned the constitution $CHO{\cdot}CH_2{\cdot}O{\cdot}CH_2{\cdot}CHO$ (*Annalen*, 1893, **276**, 65). In our view, the present discussion makes it practically certain that the course of the reaction is to be represented as follows :

$$(CH_2{\cdot}OH)_4C \longrightarrow (CH_2{\cdot}OH)_2C\begin{matrix}CHO\\CHO\end{matrix} \longrightarrow CH_2O + HO{\cdot}CH_2{\cdot}C\begin{matrix}CHO\\CH{\cdot}OH\end{matrix}$$

But our preliminary experiments to verify this hypothesis have shown that the task of preparing the dialdehyde in any quantity is likely to be laborious, since our yield of the characteristic bisphenylhydrazone described by Rave and Tollens was exceedingly small.

The difference between the nitroso- and the carbonyl group illustrated by these various reactions is one of degree, and is attributable to the fact that the nitrogen atom is more nearly equal to the oxygen atom than is the carbon atom in its tendency to acquire electrons. A system, therefore, in which nitrogen and oxygen atoms compete for four electrons is less likely to be stable than a similar one in which carbon occupies the place of nitrogen.

Experimental.

The solutions of sodium nitrite and potassium hydroxide employed in the following experiments contained respectively 64 g. and 53·6 g. in 120 c.c., as recommended by Meyer and Constam (*loc. cit.*).

β-*Hydroxyethylnitrolic Acid* (V).—Demuth and V. Meyer (*Annalen*, 1890, **256**, 43) were unable to obtain this compound either from β-nitroethyl alcohol or from the sodium salt, the preparation of which serves as a means of purifying the alcohol obtained by the usual method from glycoliodohydrin. Although the nitroethyl alcohol employed in our work was carefully purified by distillation at 101°/15 mm. (corr.) (compare Henry, *Rec. trav. chim.*, 1898, **17**, 2), we also were unable to isolate the nitrolic acid in experiments conducted under exactly the same conditions (the amount of alkali used was, however, three times as great in order to convert the nitro-compound into its salt) as those applied to the sodium salt in the manner now to be described.

β-Nitroethyl alcohol (13 g.) was converted into its sodium salt by treatment with a solution of sodium (3·3 g.) in alcohol (90 c.c.),

A solution of the sodium salt (11·4 g.) in water (5 c.c.), aqueous sodium nitrite (17 c.c.), and potassium hydroxide solution (5·6 c.c.), having been gradually acidified between — 10° and 0° with dilute sulphuric acid (5*N*), was again rendered alkaline and, after a few moments, re-acidified (compare Meyer and Constam, *loc. cit.*; Wieland, *Annalen*, 1907, **353**, 82). The solution was then rapidly filtered from sodium sulphate and extracted three times with cooled purified ether. Finally, the extract (40 c.c.), having been washed in a little ice-water and dried over sodium sulphate, was evaporated in a vacuum desiccator, first over sulphuric acid and then over phosphoric oxide. Crystallisation set in after 1 hour, when almost the whole of the ether had been removed, and the pure *nitrolic acid* (4 g.), m. p. 76—77° (decomp.; corr.), was obtained (Found: N, 23·2. $C_2H_4O_4N_2$ requires N, 23·3%). The poor yield (33%) was due to the solubility of the acid in water and to the undesirability of increasing the volume of ethereal extract and consequently delaying isolation of the product. It could be crystallised from solution in the minimum volume of dry ether by addition of three volumes of light petroleum, but gradually decomposed with evolution of nitrous fumes, even in a vacuum desiccator.

When an exactly similar experiment was performed with an equimolecular proportion of the sodium salt of β-nitropropane-αγ-diol (Wilkendorf and Trénel, *loc. cit.*) each addition of sulphuric acid was followed by the appearance of a temporary blue coloration, which rapidly changed to red. The product, m. p. 76—77° (decomp.) (Found: N, 22·9, 23·2%), did not depress the melting point of the specimen of β-hydroxyethylnitrolic acid obtained from β-nitroethyl alcohol. In order satisfactorily to demonstrate the production of formaldehyde in the reaction, it was necessary to examine the aqueous liquors under conditions which would avoid as far as possible decomposition of unextracted nitrolic acid into glycollic acid, and also to separate the formaldehyde from any of this acid which might nevertheless be produced. The liquors were therefore at once shaken with an excess of calcium carbonate at the ordinary temperature and the formaldehyde was removed by distillation after 24 hours. The distillate, which reduced Tollens's solution, was treated with β-naphthol in presence of hydrochloric acid, and furnished methylenedi-β-naphthol which, alone or mixed with an authentic specimen, melted at 206° (corr.).

Ethylnitrolic Acid from β-Nitropropanol.—A solution of sodium (5·7 g.) in methyl alcohol (40 c.c.) was very slowly added to a vigorously stirred solution of nitroethane (16 g.) and paraformaldehyde (6·6 g.) in methyl alcohol (120 c.c.). Owing to its solubility in methyl alcohol, the yield of the *sodium* salt of β-nitropropanol

(Found: N, 11·3; Na, 18·1.* $C_3H_6O_3NNa$ requires N, 11·0; Na, 18·1%) which separated from the solution was only 50%.

From the sodium salt (3·4 g.) and sodium nitrite (5 c.c.) and potassium hydroxide (1·7 c.c.) solutions, by the procedure already detailed in the case of nitroethyl alcohol, ethylnitrolic acid (2·7 g.), m. p. 84—85° (decomp.; corr.), was obtained. It was identified by analysis (Found: N, 26·6. Calc. for $C_2H_4O_3N_2$: N, 26·9%) and by direct comparison with a specimen, m. p. 85° (decomp.; corr.), prepared from nitroethane. The aqueous liquor from the preparation furnished a distillate in which formaldehyde was identified by condensation with β-naphthol; the methylenedi-β-naphthol obtained melted at 206° (corr.).

THE UNIVERSITY, SYDNEY. THE COLLEGE OF TECHNOLOGY, MANCHESTER.

CCCLVII.—*The 3-Halogeno-2-, -4-, and -6-aminophenols.*

By HERBERT HENRY HODGSON and ARNOLD KERSHAW.

THE compounds herein described include all the 3-halogeno-2-, -4-, and -6-aminophenols except the fluoro-compounds. They are much stabler than the unsubstituted aminophenols, remaining colourless after prolonged exposure to air and having no action on Fehling's solution. Ammoniacal silver nitrate, however, is reduced, rapidly by the 3-halogeno-6-aminophenols (order: Cl>Br>I), much more slowly by the 3-halogeno-2-aminophenols (I>Br>Cl), and relatively most slowly by the 3-halogeno-4-aminophenols (Cl>Br>I). The solubilities of the 3-halogenoaminophenols in water decrease in the order Cl>Br>I. The hydrochlorides of the 3-halogeno-2- and -6-aminophenols are very soluble in water; those of the 4-amino-isomerides are only moderately easily soluble.

EXPERIMENTAL.

General Method of Preparation.—The 3-halogeno-2-, -4-, and -6-nitrophenols are dissolved in hot aqueous sodium hydroxide, and solid sodium hyposulphite is gradually added. The resulting 3-halogenoaminophenols all crystallise from water containing a little sodium bisulphite, and their hydrochlorides from dilute

* The result of the nitrogen determination was only satisfactory when the salt was mixed with potassium dichromate (compare Schmidt and Wilkendorf, *loc. cit.*). For the sodium determination, the salt was moistened with water before treatment with sulphuric acid.

hydrochloric acid, in colourless needles or plates. The hydrochlorides melt with extensive decomposition.

The 3-Halogeno-2-aminophenols.—Colour reactions. (1) Ferric chloride produces a transient reddish-violet colour and then a brown precipitate, the solution of which in concentrated hydrochloric acid retains its deep brownish-red colour on dilution. (2) Bleaching powder solution produces a light brown precipitate which deepens in colour on the gradual addition of hydrochloric acid but finally dissolves, forming deep brown solutions from the chloro- and bromo-compounds and a yellow solution from the iodo-compound. (3) Bromine water gives initially a brown coloration and then a pale yellow precipitate, the solution of which in hydrochloric acid is yellow.

3-Chloro-2-aminophenol, flat needles, m. p. 122° (Found : Cl, 24·8. C_6H_6ONCl requires Cl, 24·7%); *hydrochloride*, plates (Found : Cl, 39·2. C_6H_6ONCl,HCl requires Cl, 39·4%). *3-Bromo-2-aminophenol*, needles, m. p. 138° (Found : Br, 42·3. C_6H_6ONBr requires Br, 42·6%); *hydrochloride*, needles (0·0930 g. gave 0·1369 g. of mixed silver halides. Calc., 0·1372 g.). *3-Iodo-2-aminophenol*, needles, m. p. 137° (decomp.) (Found : I, 54·2. C_6H_6ONI requires I, 54·0%); *hydrochloride*, plates (0·1597 g. gave 0·2228 g. of mixed silver halides. Calc., 0·2226 g.).

The 3-Halogeno-4-aminophenols.—Colour reactions. (1) Ferric chloride gives with the chloro- and bromo-compounds intense violet colours which are changed to greenish-brown by concentrated hydrochloric acid and restored on dilution, whereas the iodo-compound gives only a faint brown colour changing to orange-brown. (2) Bleaching powder solution produces with the chloro- and bromo-compounds purple colorations and then brown precipitates giving orange-brown solutions in hydrochloric acid, whereas the iodo-compound exhibits only a faint violet coloration changing to light yellow on acidification. (3) Bromine water produces initially a violet colour, followed by a light brown or buff precipitate soluble in hydrochloric acid to a golden-brown solution.

3-Chloro-4-aminophenol, long, flat needles, m. p. 159·5° (Found : Cl, 24·5%) (compare D.R.-P. 143449, 1903); *hydrochloride*, plates (Found : Cl, 39·2%). *3-Bromo-4-aminophenol*, very long needles, m. p. 151° (Found : Br, 42·6%); *hydrochloride*, prisms (0·2221 g. gave 0·3285 g. of mixed silver halides. Calc., 0·3278 g.). *3-Iodo-4-aminophenol*, plates, m. p. 145·5° (Found : I, 53·8%); *hydrochloride*, plates (0·1180 g. gave 0·1650 g. of mixed silver halides. Calc., 0·1645 g.).

The 3-Halogeno-6-aminophenols.—Colour reactions. (1) Ferric chloride gives initially a bright violet colour, followed by a dark

purple precipitate the reddish-brown solution of which in concentrated hydrochloric acid becomes violet on dilution. (2) Bleaching powder solution produces a transient violet coloration, followed by a deep brown precipitate which rapidly changes to a bright red gelatinous form soluble in hydrochloric acid to an eosin-red solution unchanged on dilution. (3) Bromine water gives initially a brown coloration, followed by a light brown precipitate soluble with difficulty in hydrochloric acid to a straw-coloured solution.

3-*Chloro*-6-*aminophenol*, prisms, m. p. 154° (Found: Cl, 24·5%); *hydrochloride*, plates (Found: Cl, 39·3%). 3-*Bromo*-6-*aminophenol*, prisms, m. p. 150° (Found: Br, 42·4%); *hydrochloride*, elongated plates (0·1137 g. gave 0·1699 g. of mixed silver halides. Calc., 0·1678 g.). 3-*Iodo*-6-*aminophenol*, long needles, m. p. 141° (Found: I, 54·2%); *hydrochloride*, plates (0·1234 g. gave 0·1727 g. of mixed silver halides. Calc., 0·1720 g.).

The authors desire to thank the Department of Scientific and Industrial Research for a grant to one of them (A. K.), and the British Dyestuffs Corporation for gifts of chemicals.

CCCLVIII.—*Adsorption and Constitution: The Adsorption of Organic Acids on Animal Charcoal.*

By KENNETH MASSY GRIFFIN, HENRY LORIMER RICHARDSON, and PHILIP WILFRID ROBERTSON.

IT has been shown that the expression C_2/C_1 gives a comparable measure of the adsorption of substances from solution (Richardson and Robertson, J., 1925, **127**, 553), *i.e.*, the order of the values of C_2/C_1 found for a number of compounds agreed with the relative position of their adsorption isotherms, the effect of initial concentration being limited to that due to differences in the slope of the isotherms. Further, the magnitude of C_2/C_1 varied over a wide range with changes in the structure of the substances compared.

The equilibrium of an adsorbed substance in contact with its solution—the adsorption isotherm—is generally expressed by the exponential formula of Freundlich, $a = \alpha c^{1/n}$, or $C_2 = KC_1^{1/n}$, which gives satisfactory results at least for dilute solutions. An examination of the values of $1/n$ for a number of widely diverse substances (Freundlich, "Kapillarchemie," 1923, 236) showed very little dependence on the nature of the molecule adsorbed: many

between 1·8 and 4·2. Richardson and Robertson (*loc. cit.*) made a similar observation with a variety of organic compounds. Apart from the ambiguity of its actual significance, therefore, and the experimental difficulties of its determination in solvents where adsorption is slight, n does not seem to be a suitable function for the examination of constitutive influences.

The relative extent to which substances are adsorbed varies much more considerably than does n: some comparative studies on this basis, of the adsorption of organic acids from aqueous solution, have been reported (Freundlich, *op. cit.*, p. 267; Bartell and Miller, *J. Amer. Chem. Soc.*, 1923, **45**, 1109). However, for a more general examination of organic compounds, owing to their slight solubility in water, organic solvents would be necessary. In the present paper, the adsorption by animal charcoal from ethyl-alcoholic solution of a number of carboxylic acids has been determined. The concentration chosen as a basis of comparison was $N/20$; C_2/C_1 was calculated from this after titration of the equilibrium filtrate, and then the "relative adsorption" with reference to a standard acid (acetic for the aliphatic series, benzoic for the aromatic) was taken for comparison. This "relative adsorption" was found to be almost independent of the activity of the charcoal.

Experimental.

The method of experiment was as described in the literature: 5 g. of charcoal were shaken mechanically for 4 hours with 50 c.c. of an $N/20$-alcoholic solution of the acid, the liquid was rapidly filtered, and 10 c.c. portions of the filtrate were titrated with $N/20$-alcoholic potash with phenolphthalein as indicator. The original solution was titrated at the same time as the filtrate from the charcoal, to allow for error due to esterification. Only those titration values that differed by less than 0·1 c.c. were accepted; agreement was generally within 0·05 c.c.

The reagents used were carefully purified. The animal charcoal was supplied by the British Drug Houses as "Animal Charcoal, Acid-free," and since it had at first a slightly alkaline reaction, it was repeatedly extracted with hot water until neutral to phenolphthalein. Before use, it was activated by heating to redness for some hours in a Vitreosil tube, a steady stream of dry nitrogen being passed through towards the end of the operation and continued until the tube was cold. After being sieved, the charcoal was kept in a large, stoppered bottle for several days before use, for its activity fell off somewhat immediately after activation. Since the amount of charcoal used in a series of experiments was considerable, it became necessary to recover it after use and reactivate it: this was

effected in the same manner as the preliminary activation. After reactivation, the activity of the charcoal as measured by a standard substance such as acetic acid was found to have changed slightly: in one series of reactivations, C_2/C_1 for acetic acid was successively 1·35, 1·19, 0·98, 1·10, 0·75; another charcoal gave 0·36, 0·46, 0·43, 0·33, 0·39. To enable comparable results to be obtained with charcoals of different activity, the values of C_2/C_1 found for a series of compounds with any one charcoal were divided by the previously determined value of C_2/C_1 for a standard acid with that charcoal. As noted above, these "relative adsorptions" obtained for any compound with different charcoals were in satisfactory agreement, but in certain instances the deviations were greater than the experimental error. It would appear that when the structure of the compounds differed considerably, the relative adsorption might be influenced to some extent by the nature of the charcoal. This is shown by observations on acetic and benzoic acids:

Charcoal.	C_2/C_1, acetic acid.	C_2/C_1, benzoic acid.	Relative adsorption (acetic acid = 1).
I	0·362	1·67	4·61
II	0·463	2·24	4·84
III	0·433	2·48	5·73
IV	0·330	2·08	6·32
V	0·387	2·59	6·69
VI	0·067	0·339	5·1

Charcoals II, III, IV, and V were obtained by successive reactivations of charcoal I; reactivation caused a slight but steady increase in the relative adsorption of benzoic acid as compared with acetic acid. Charcoal VI was a sample of different origin, and considerably less active; the value it gave for the relative adsorption of benzoic acid fell amongst those of the previous charcoals. The other aromatic acids resembled benzoic acid in showing appreciable deviations among their relative adsorptions with different charcoals, when the value for acetic acid was taken as unity. For this reason, the values for their relative adsorptions that appear in Table II were calculated on the basis of benzoic acid; the results so obtained showed satisfactory agreement for different samples of charcoal.

In Tables I and II are given the mean values found for the relative adsorptions from alcoholic solution of aliphatic and aromatic acids, respectively. For the former, acetic acid was taken as standard; for the latter, benzoic.

The effect of constitution is on the whole definite. In the normal fatty acids, the adsorption falls to a minimum and then rises with increasing molecular weight; further, the property is an alternating one, the odd-numbered members being less adsorbed than the even.

TABLE I.

Acid.	Relative adsorption.	Acid.	Relative adsorption.
Acetic	1·00	Lactic	0·58
Propionic	0·65	Phenylacetic	3·26
Butyric	0·87	Phenylpropionic	4·04
*iso*Butyric	0·27	Cinnamic	6·25
*iso*Valeric	0·21	Mandelic	2·29
Hexoic	1·13	Succinic	1·44
Heptoic	0·92	Adipic	1·05
Octoic	1·50	Sebacic	2·30
Nonoic	1·32	Monobromosuccinic	1·77
Lauric	2·15	Ethylsuccinic	0·85
Stearic	2·32	Malic	1·22
Monochloroacetic	2·31	Tartaric	1·60
Trichloroacetic	0·27	Fumaric	4·15
Monobromoacetic	2·70	Citraconic	5·54
α-Bromopropionic	1·92	Mesaconic	3·41
α-Bromo*iso*butyric	1·38		

With regard to the effect of substituents, small alkyl groups and the hydroxyl group reduce the adsorption, and halogen (except in trichloroacetic acid) and the phenyl group increase it. Dibasic acids are adsorbed more strongly than the corresponding monobasic acids. Unsaturation (the ethylenic link) causes an especially marked increase in relative adsorption.

TABLE II.

Acid.	Relative adsorption.	Acid.	Relative adsorption.
Benzoic	1·00	*p*-Nitrobenzoic	3·64
o-Toluic	0·97	*o*-Chlorobenzoic	0·86
m-Toluic	1·19	Salicylic	1·64
p-Toluic	1·36	*o*-Acetoxybenzoic	0·75
o-Bromobenzoic	1·01	*p*-Methoxybenzoic	2·30
m-Bromobenzoic	2·10	Phthalic	2·30
p-Bromobenzoic	2·42	*o*-Aminobenzoic	2·91
o-Nitrobenzoic	1·34	*o*-Acetamidobenzoic	2·30
m-Nitrobenzoic	3·32	*s*-Tribromobenzoic	2·51

Generally the relative adsorption of the aromatic acids is 5 to 20 times that of the aliphatic acids (compare table, p. 2707). Substituents in the para-position increase the relative adsorption, the effect of the groups being in the order alkyl, halogen, nitro-; in the meta-position there is a corresponding but smaller enhancement; and ortho-substitution has usually a smaller or even a depressing effect. The enhancement attributable to *o*-hydroxy- and *o*-amino-groups was reduced by acetylation. As in the aliphatic series, the additional carboxyl group of a dibasic acid increased adsorption.

Summary.

1. The relative adsorption of organic acids from alcoholic solution, on animal charcoal, varies within wide limits; *e.g.*, *iso*valeric acid

has the value 0·21, and *p*-nitrobenzoic acid 17, if acetic acid is taken as unity.

2. In general, the relative adsorption tends to increase with molecular weight, but this increase is subject to marked constitutive effects.

3. Aromatic acids are much more strongly adsorbed than aliphatic acids; substitution, especially in the para-position, increases the adsorption.

VICTORIA UNIVERSITY COLLEGE,
WELLINGTON, N.Z. [*Received, August 23rd*, 1928.]

CCCLIX.—*Polymerides of Aliphatic Chloroaldehydes.*

By FREDERICK DANIEL CHATTAWAY and EDWIN GEOFFREY KELLETT.

THE known polymerides of the aliphatic chloroaldehydes may be grouped in two classes, the so-called meta- and para-aldehydes. The meta-compounds are insoluble, colourless, amorphous solids, which on heating volatilise and dissociate without previously melting; they have no properties which afford a guide to their constitution, since in all reactions they revert to and react as the unpolymerised forms, and their molecular complexity is unknown. Metachloroacetaldehyde (Natterer, *Monatsh.*, 1882, **3**, 447) and metadichloroacetaldehyde (Friedrich, *Annalen*, 1881, **206**, 52) are readily formed from the free aldehydes under the influence of hydrogen chloride, whilst strong sulphuric acid causes the formation of polymerides of a different type—the para-aldehydes (Natterer, *loc. cit.*; Jacobsen, *Ber.*, 1875, **8**, 88). These are colourless, crystalline solids having sharp melting points, and being soluble in most organic solvents, though insoluble in water. They are comparatively stable, being unaffected by, *e.g.*, boiling aqueous alkalis. On distillation under ordinary pressure they dissociate, but under diminished pressure they volatilise unchanged. They are trimeric, and their constitution is usually represented by a six-atom ring.

Although chloral has long been known to give a polymeride of the meta-type, it has not hitherto been found to give one of the para-type. When, however, a solution of chloral in strong sulphuric acid is allowed to remain at the ordinary temperature, two isomeric *parachlorals* are formed in addition to the metachloral which is the main product, and they may be extracted from the latter by hot alcohol. By fractional crystallisation from the same solvent, they can be separated from each other and from chloralide

$$(CCl_3\cdot CH\cdot O\cdot CH\cdot CCl_3,\ CO\cdot O)$$

trichloroethylidene trichlorolactic ester), which is formed to some

extent at the same time and is considerably less soluble than either. The production of these polymerides appears to depend on the temperature: at or below 0°, metachloral is the sole product, whilst at 40°, a relatively large amount of chloralide is also formed.

Both isomerides show the characteristic properties of true paraldehydes: they have sharp melting points, and are readily soluble in organic solvents, though insoluble in hot or cold water. Cryoscopic molecular-weight determinations in benzene show each to be trimeric, and although they dissociate into chloral on distillation under ordinary pressure, they distil unchanged under a pressure of 15 mm. The less soluble and more soluble forms are termed α- and β-parachloral, respectively.

These two isomerides and metachloral are formed independently, for in the presence of sulphuric acid none is converted into either of the others. It seems probable that the isomerism of α- and β-parachloral is of the *cis-trans* type, corresponding to the two possibilities in the paraldehyde ring, one having all three trichloromethyl residues on the same side of the plane of the ring, and the other having two on one side and one on the other. Isomerism which has similarly been attributed to *cis-trans* forms has been observed in parabromopropaldehyde (Franke, *Annalen*, 1907, **351**, 421), in trichloralimide, $(CCl_3{\cdot}CH{:}NH)_3$ (Béhal and Choay, *Ann. Chim. Phys.*, 1892, **26**, 7, 34), and in the trithioaldehydes, $(R{\cdot}CH{:}S)_3$ (Baumann and Fromm, *Ber.*, 1891, **24**, 1426), and in the last case this type of isomerism has been confirmed, since on oxidation the *cis*-form gives only one disulphone-sulphide, whereas the *trans*-form gives two. One form is converted into the other by the action of acetyl chloride, iodine, etc. Attempts to effect interconversion of the two parachlorals by the same means have been unsuccessful, however.

It is noteworthy that this is the first time that a meta-form and two isomeric para-forms of the same aldehyde have been obtained. The assumption that the relation of the meta- and para-forms is that of *cis-trans* isomerides (compare *Ber.*, 1907, **40**, 4341) can thus no longer be accepted, at least in the case of chloral.

Paradichloroacetaldehyde does not appear to exist in isomeric forms, for sulphuric acid converts it into a single compound, which decomposes when kept for more than a few hours in contact with the acid; it is possible, however, that the failure to isolate a second isomeride is due to its still more rapid decomposition.

Butylchloral, $CH_3{\cdot}CHCl{\cdot}CCl_2{\cdot}CHO$, like chloral, forms two isomeric polymerides of the para-type when kept in contact with excess of sulphuric acid; these differ in solubility and can be separated by fractional crystallisation from acetic acid. The terms α- and β- may be applied to the less soluble and more soluble

forms as before. In properties they closely resemble the para-chlorals, being colourless, crystalline, sharp-melting compounds, soluble in organic solvents, but insoluble in water. They are trimeric, and can be distilled unchanged under a pressure of 15 mm., but dissociate into butylchloral on distillation under ordinary pressure.

It may be noted that the α-forms of parachloral, parabutylchloral, and trichloralimide all crystallise in the orthorhombic system. Béhal and Choay (*loc. cit.*) infer from the crystal symmetry a corresponding molecular symmetry, and designate the α-form "*cis*" and the β-form "*trans*"; but this conclusion seems hardly justifiable.

Butylchloral appears not to form a polymeride of the meta-type; in fact, no meta-polymerides of chloro- or bromo-aldehydes have been observed outside the acetaldehyde group.

EXPERIMENTAL.

Preparation of α- and β-Parachloral.—The most suitable conditions for the preparation of these isomerides are (*a*) a temperature of 15—20°, and (*b*) a large excess of sulphuric acid, and it appears to be essential that the chloral should first dissolve, for metachloral is formed as a crust when a layer of chloral is left floating on the surface of the acid.

Powdered chloral hydrate (100 g.) was added slowly to concentrated sulphuric acid (1000 g.), each portion being shaken until dissolved. On standing for a few hours at the ordinary temperature, a mixture of the three polymerides with chloralide began to separate as a white powder. After 3 days, this solid was filtered off, washed with hot water until the smell of chloral could no longer be recognised, dried, powdered, and extracted with boiling alcohol (100 c.c. to 50 g. of product). The chloralide, which separated from the cold extract, was removed, and cold water added to the filtrate. The colourless precipitate was separated, dried, and boiled for a few seconds with sufficient alcohol to dissolve half of it; evaporation of the extract gave a residue rich in the β-form, and the two solids were then repeatedly recrystallised from alcohol until the two forms were obtained pure and of constant m. p.

α-*Parachloral* crystallises from boiling alcohol in compact, colourless, rhombic crystals (Found: Cl, 72·02; *M*, cryoscopic in benzene, 423. $C_6H_3O_3Cl_9$ requires Cl, 72·16%; *M*, 442). It melts at 116° *

* It may be noted that this m. p. is very near to that of chloralide (115—116°), which, however, boils at 272° without change. The mixed m. p. of the two may be as low as 85—90°. The monoclinic crystalline form of chloralide (*Z. Kryst.*, 1877, 1, 594) is quite different from the rhombic form of α-parachloral. Further, chloralide is decomposed by boiling aqueous alkalis.

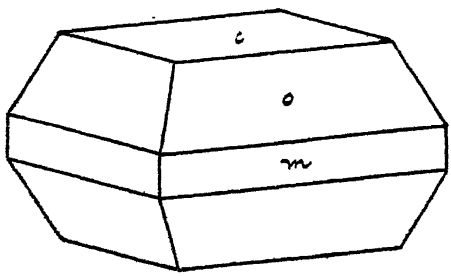
and boils at 223°/760 mm. The b. p. was determined by the capillary-tube method; in an ordinary distillation apparatus the b. p. rises, owing to decomposition, whilst a thermometer in the vapour registers 98·0°, the b. p. of chloral. Even in a vacuum distillation apparatus under 15 mm. pressure the boiling point was found not to be constant, as some decomposition occurred, but a quantity of unchanged α-parachloral collected in the condenser.

Dr. T. V. Barker, of Brasenose College, has very kindly examined the crystals, and reports that they are orthorhombic, as shown in Fig. 1. The forms developed were *c* (001), *o* (111), and *m* (110). The axial elements, $a : b : c = 0{\cdot}8801 : 1 : 1{\cdot}4505$, were computed from the following mean measurements derived from two crystals:

$$mm \quad (110 : 1\bar{1}0) = 84°\ 42', \quad co \quad (001 : 111) = 65°\ 31'.$$

β-*Parachloral* crystallises from alcohol in long, colourless prisms (Found: Cl, 71·95%; *M*, cryoscopic in benzene, 420), too slender to

FIG. 1.



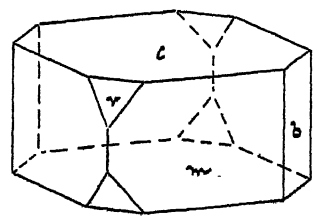


FIG. 2.

admit of measurement. It melts at 152° and boils at 250° (in the capillary tube). Its behaviour on distillation is similar to that of the α-form.

The yield of α- and β-parachloral obtained as above is not more than 1% of the chloral taken: about 2% of chloralide is also formed. These polymerides have none of the characteristic properties of chloral: they are odourless, stable to boiling aqueous alkalis, and do not react with phenylhydrazine or potassium cyanide.

Preparation of α- and β-Parabutylchloral.—In order to obtain a good yield of these polymerides, not less than 6 parts by weight of concentrated sulphuric acid to one part of butylchloral hydrate should be used. With a smaller amount polymerisation is slow, and this probably explains why Willcox and Brunel (*J. Amer. Chem. Soc.*, 1916, **38**, 2538), who used sulphuric acid for dehydrating butylchloral hydrate, failed to observe the formation of the polymerides. 150 G. of concentrated sulphuric acid were poured on 25 g. of

›wdered butylchloral hydrate and shaken until a homogeneous brown ıuid was formed. In about 2 hours the solid polymerides began · separate, and after standing with occasional shaking for about ?o days, the mixture became almost solid. Ice was then added, ıd the caked product which separated was broken up, thoroughly ashed with hot water until the smell of butylchloral could no nger be detected, dried, and fractionally crystallised from acetic ıid. The total yield of the two isomerides before separation was ›out 80% of the butylchloral taken.

α-Parabutylchloral crystallises from boiling acetic acid (in which is moderately soluble) or from boiling alcohol (in which it is ›aringly soluble) in compact, colourless, rhombic crystals, m. p. 30°, b. p. 255°/760 mm. (in the capillary tube) (Found: Cl, 60·6; ', cryoscopic in benzene, 484. $C_{12}H_{15}O_3Cl_9$ requires Cl, 60·66%; ', 526). Its behaviour on distillation under atmospheric pressure ' in a vacuum resembles that of α-parachloral.

Mr. W. R. C. Curjel, of Keble College, has kindly examined the ystals, and reports that they are orthorhombic (Fig. 2). The ıial elements are $a : b : c = 0{\cdot}8209 : 1 : 1{\cdot}4460$. The forms ›served were *c* (001), *b* (010), *m* (110), *r* (101), and, less frequently, (111). Mean values for the interfacial angles are:

$110 : 1\bar{1}0 = 78°\ 46'$	$110 : 111 = 23°\ 35'$
$110 : 101 = 47°\ 46'$	$101 : 111 = 35°\ 24'$
$001 : 101 = 60°\ 22'$	

β-*Parabutylchloral* crystallises from boiling acetic acid or alcohol ı which it is considerably more soluble than the α-form) in usters of very small, colourless crystals (Found: Cl, 60·6%; ', 479), m. p. 157°, b. p. 233°/760 mm. (capillary tube). In ·operties and behaviour on distillation it closely resembles the ›lymerides already described.

Preparation of Anhydrous Butylchloral.—In order to attempt the ·eparation of a meta-polymeride, it was necessary to prepare ıhydrous butylchloral from the hydrate. Neither the method of 'illcox and Brunel (*loc. cit.*), who used sulphuric acid as dehydrating ;ent, nor that of Pinner (*Ber.*, 1870, **3**, 383), who distilled the ?drate in a stream of dry hydrogen chloride, was found satisfactory. A suitable method is to distil the hydrate with about half its eight of acetic anhydride under a short fractionating column. A ›nsiderable portion of acetic acid distils at 120—130°, and the ıermometer then rises rapidly to 165° (the b. p. of butylchloral), at hich it remains constant practically till the end of the distillation. he fraction which distils at 165° is redistilled and dried in a vacuum ›siccator. The distilling apparatus should be thoroughly dry,

and the receiver protected by a calcium chloride tube, to prevent re-formation of the hydrate.

The anhydrous aldehyde is also conveniently prepared by distilling the dry polymerides under ordinary pressure; they need not be separated for this purpose, and are converted quantitatively into the unimolecular form.

Action of hydrogen chloride. Since mono- and di-chloroacetaldehyde are readily converted into meta-polymerides under the influence of hydrogen chloride (which also induces the formation of metachloral from chloral, though in this case it is much less effective than sulphuric acid), the prolonged action of hydrogen chloride in the cold on butylchloral was investigated. The chloral was saturated with the dry gas and sealed up, but no action occurred even on standing for a long period. A similar experiment was then carried out with butylchloral alcoholate (which absorbs more of the acid), the mixture being well cooled in order to avoid formation of the acetal (compare Freundler, *Bull. Soc. chim.*, 1907, **1**, 201), but no action occurred.

Action of pyridine. Chloral is rapidly converted into metachloral in the presence of $\frac{1}{12}$ mol. of pyridine (Böeseken, *Rec. trav. chim.*, 1913, **32**, 112); 9 g. of butylchloral were therefore sealed up with 0·4 g. of pyridine, the two liquids being readily miscible. After standing for 5 days, the liquid had turned dark brown, and 1·5 g. of a white solid had separated. This was filtered off and washed with a little cold alcohol and hydrochloric acid; it proved to be a mixture of the two parabutylchlorals.

CCCLX.—*The Formation of Liesegang Rings as a Periodic Coagulation Phenomenon.*

By ERNEST SYDNEY HEDGES and ROSALIND VENETIA HENLEY.

DURING the past 32 years, a vast amount of experimental work has been performed on the production of stratified precipitates in gels, and from this work there emerges the important fact that the phenomenon is of a general nature; indeed, it is probable that, given the right conditions, rhythmic banding of a precipitate can be formed from any pair of interacting salts. Most of the numerous theories which have been advanced to account for the observed phenomena apply only to the particular case studied (see Hedges and Myers, "The Problem of Physicochemical Periodicity," 1926,

E. Arnold and Co.), but reference may be made to the four most important theories which are of general applicability, *viz.*, those of Wilhelm Ostwald ("Lehrbuch der allgemeinen Chemie," Leipzig, 2nd edn., 1891, ii, 778), Bradford (*Biochem. J.*, 1916, **10**, 169; 1917, **11**, 14), Dhar and Chatterji (*Kolloid-Z.*, 1922, **31**, 15; 1925, **37**, 2), and Wo. Ostwald (*ibid.*, 1925, **36**, 380).

The reactions which give rise to these banded precipitates are often designated as "rhythmic" or "periodic," but there is nothing to suggest that the reaction–time curve is periodic, and it is therefore proposed to apply the term "periodic structures" to the cases under discussion, and to restrict the term "periodic reactions" to chemical processes where it can be shown that the reaction velocity varies periodically. One of the aims of the present research has been to obtain evidence on this aspect of the matter by determining whether the bands of precipitate are formed primarily in the diffusing wave-front, or whether the banding is a secondary phenomenon occurring after formation of the substance. We believe that we have definitely established the truth of the latter view.

Experimental.

The System Silver Dichromate–Gelatin.

When a large drop of 20% silver nitrate solution is placed on a 10% gelatin gel containing 0·4% of potassium dichromate, it is generally observed that in the initial stages of diffusion concentric rings of precipitate are formed at the edge of the diffusing wave-front, and somewhat later the rings are surrounded by a pale yellow fringe. The fringe increases gradually in breadth, often to the extent of 1 cm. or more.

By conducting the experiment in a test-tube, down the outside of which a thin strip of paper is pasted, and marking the positions of the extreme edge of the yellow fringe and of the last red ring after various time intervals, it can readily be shown that the rings are formed some distance behind the diffusing wave-front. These observations cannot be taken as evidence that the production of rings is a secondary effect, since the nature of the pale yellow fringe is not definitely known. Friend (J., 1922, **121**, 472) regards it as colloidal silver chromate, whereas according to Riegel and Reinhard (*J. Physical Chem.*, 1927, **31**, 713) it consists of silver chloride, formed by the sodium chloride present as an impurity in commercial gelatin. It is stated that no such haze is produced if the gelatin has previously been washed thoroughly. Our observations support the view of Riegel and Reinhard, but we cannot agree with them that the production of red rings of silver dichromate

is dependent on the substructure due to the chloride; for we find that after the chloride in a gelatin sol has been completely precipitated by dilute silver nitrate solution and the stirred liquid allowed to set to a structureless gel with addition of potassium dichromate, good rings are produced by allowing 20% silver nitrate solution to diffuse into the gel. Further, if a drop of 20% silver nitrate solution be placed on the yellow fringe in the ordinary diffusion experiment, an independent ring system develops immediately, which can bear no relation to the pre-existent substructure.

Experiments to be described later have shown that when very dilute solutions of silver nitrate and potassium dichromate are mixed together in gelatin no precipitate is formed, the product apparently remaining in a colloidal state, protected by the gelatin. A considerable excess of silver nitrate causes coagulation of the colloid to a red precipitate. It seems unlikely, therefore, that silver dichromate is precipitated in the direct chemical reaction during the course of the formation of Liesegang rings, but rather that the first product of the reaction is colloidal silver dichromate, which is afterwards coagulated in rings by excess of the diffusing silver nitrate.

An experiment was devised to separate the chemical reaction and the coagulation into two stages and to determine which stage is responsible for the periodicity. The method consisted in adding to the gelatin–potassium dichromate mixture an equivalent quantity of silver nitrate and, after the mixture had set to a gel, causing 20% silver nitrate solution to diffuse into it. To conduct this experiment, it does not suffice to add directly to the gelatin equivalent quantities of the two reactants, for the chlorides, etc., in the gelatin dispose of some of the silver nitrate preferentially, leaving some potassium dichromate free. It was necessary, therefore, to determine the substances in the gelatin which could react preferentially with silver nitrate. This was done by igniting a weighed amount of gelatin and titrating the aqueous extract of the ash with silver nitrate in presence of potassium dichromate as an indicator. Since the composition of one gelatin leaf differs from that of another from the same source, a large amount of 10% gelatin sol was prepared and 25 c.c. were withdrawn for the analysis, which was thus performed on the same sol as that used for the experiments. The sol (25 c.c.) was evaporated to dryness in a platinum dish and finally heated over the blowpipe until the ash attained a constant weight, which was 1·64% of the weight of dry gelatin. This amount of ash (0·0410 g. in 25 c.c.) was equivalent to 2·95 c.c. of 0·5% silver nitrate solution.

From these data, a sol of silver dichromate in 5% gelatin was

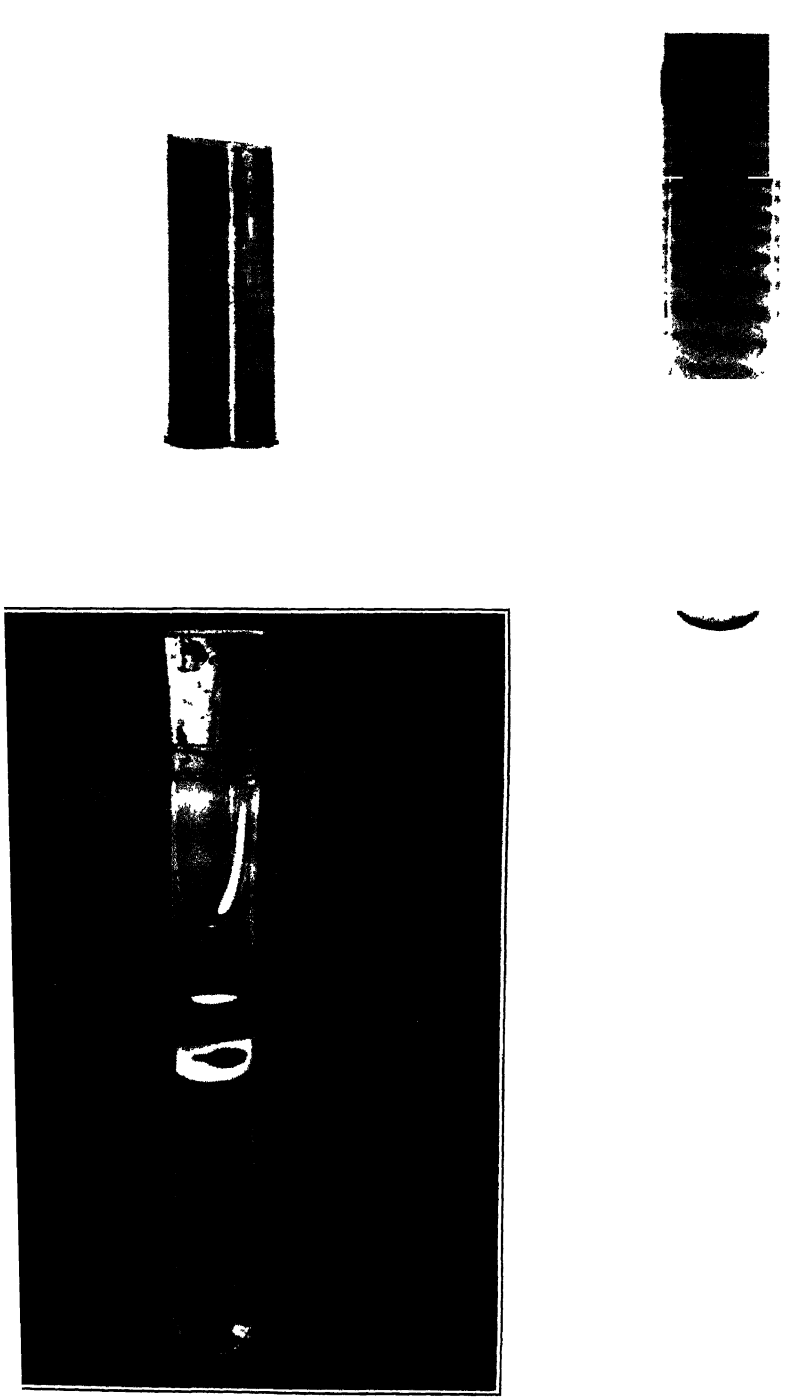

FIG. 4.

made by mixing (*a*) 20 c.c. of 10% gelatin + 20 c.c. of 0·2871% potassium dichromate solution with (*b*) 20 c.c. of 10% gelatin + 14·74 c.c. of 0·5% silver nitrate solution. After the mixture had set to a gel in a number of test-tubes, 20% silver nitrate solution was poured over the top: the resulting periodic structure due to coagulation is reproduced in Fig. 1. The bands are as well defined as those produced by chemical reaction, and, moreover, they are subject to the same peculiarities; for example, the bands in one tube formed a spiral. The silver dichromate was not coagulated by diffusing a saturated solution of potassium dichromate into the gel.

In a second series, a 30% excess of silver nitrate was added to silver dichromate in gelatin. Bands were produced by diffusing 20% silver nitrate solution into the mixture, but they were not so well marked as in the former case, a considerable amount of precipitation occurring in the spaces between the bands. In this system, bands were formed by the interdiffusion of a saturated solution of potassium dichromate, affording confirmation that there was excess of silver nitrate in the gel.

The experiments indicate that the banding is not concerned with the chemical reaction, but is a secondary phenomenon occurring after the reaction. The two stages have been separated, the chemical reaction having been carried out first without periodic phenomena, and a stratified precipitate being produced in the second stage of coagulation by excess of silver nitrate.

Measurement of the Critical Concentration of Silver Nitrate.

The experiments described in this section were designed, not only to gain an idea of the critical concentration of silver nitrate necessary to coagulate silver dichromate under the conditions prevailing in the former experiments, but also to test the suggestion made by Hedges and Myers (*op. cit.*, p. 27), that the formation of periodic structures may have its explanation in the periodic opacity phenomenon of Holker (*Proc. Roy. Soc.*, 1923, *A*, **102**, 710). According to this author, the opacity of a precipitated colloid is in many cases a periodic function of the concentration of the precipitating electrolyte, and the suggestion was made (Hedges and Myers, *op. cit.*) that, since in the formation of a periodic structure the advancing diffusion wave is subject to a progressive dilution, a series of opacity bands is to be expected, corresponding with the peaks of Holker's curves. If such be the case, one would expect that, when a series of test-tubes containing colloidal silver dichromate in gelatin is treated with progressively increasing concentrations of silver nitrate (each tube receiving a higher concentration than its predecessor), then precipitation would occur in some tubes and not in others,

the arrangement being periodic throughout the series, but the experiments do not lend any support to this view.

To each of a series of tubes containing 5 c.c. of silver nitrate solution were added 5 c.c. of a sol prepared by mixing equal volumes of 0·125% silver nitrate in 5% gelatin and 0·1435% potassium dichromate in 5% gelatin. Silver nitrate solutions were examined over the concentration range 0·1% to 3·0%. All the solutions up to and including 0·29% silver nitrate remained a clear yellow after addition of the silver dichromate–gelatin mixture, but a red precipitate was produced in the 0·30% solution. A further series was conducted with twelve tubes in which the concentration was varied from 0·288% to 0·299% at intervals of 0·001%. At first sight it seemed that there was actually a periodic change, produced by progressively increasing concentration. It appears, however, that the production of precipitate in any one tube is fortuitous, depending, for instance, on the nuclei provided by the tube and on the rate of mixing. The whole series was repeated three times in tubes which had previously been soaked thoroughly in a mixture of nitric and chromic acids. In these experiments there was a complete lack of correspondence in the behaviour of individual tubes: those concentrations which were the first to give a red precipitate in one experiment were the last to retain their yellow colour in the next. No reliance can be placed, therefore, on values of critical concentration measured in terms of less than 0·01%. The critical concentration required to coagulate colloidal silver dichromate under the conditions described may be taken as 0·29%.

We believe that these observations offer a satisfactory explanation of the unpublished experiment performed by Holker and reported by Hedges and Myers (*op. cit.*, p. 27).

The System Lead Iodide–Agar.

Periodic structures can readily be obtained by diffusing 30% lead nitrate solution into an agar gel containing potassium iodide (see Hatschek, "Laboratory Manual of Colloid Chemistry," 1925, p. 144). This system has been treated in the same manner as the preceding one, and it has again been shown that the chemical reaction can be carried out first, the bands being obtained subsequently by coagulation.

Equal volumes of 1% agar solutions containing 0·6% of potassium iodide and 0·6% of lead nitrate (equivalent weights) were mixed while hot and allowed to set in test-tubes. On cooling, the lead iodide did not separate, although its solubility in water was exceeded many times. However, when kept for some days, such gels gave a yellow deposit in patches on the side of the test-tube.

30% Lead nitrate solution was poured into the space above the gel in two tubes; after 2 days, five successive discs had appeared in the tube. These discs did not reach to the walls of the tube, but were suspended in the gel; the first two were sharply defined, and the remainder more diffuse; the mean distance between the bands was about 1 cm., becoming greater with increasing depth in the tube.

Diffusion of 20% potassium iodide solution into another tube gave a ring system comparable in every respect with that produced by chemical reaction. Within an hour, numerous fine bands were visible. It seems that in this instance either of the reactants serves as a coagulating agent, but potassium iodide is much more effective than lead nitrate.

In order to eliminate any possible complications due to the concomitant production of potassium nitrate in making up the gel mixture, the experiments were repeated and extended in agar gels containing lead iodide in absence of other electrolytes. These were prepared by dissolving recrystallised lead iodide in 1% agar solution at 100°, and allowing it to cool. A few trials indicated that the cooled gel would hold as much as 0·2% of lead iodide, although the solubility in water at the ordinary temperature is only 0·04%.

A number of test-tubes containing 1% agar gel with 0·2% lead iodide were treated with various diffusing agents. Periodic structures, exactly similar to those described for gels prepared by the former method, were produced when 30% lead nitrate or 20% potassium iodide was the diffusing solution. An example of the bands produced when potassium iodide diffused into the gel is given in Fig. 2.

Other solutions were allowed to diffuse into the above mixture and bands were observed in some cases; 20% silver nitrate, 20% sodium carbonate, and a saturated solution of mercuric chloride gave rings, but 30% aluminium sulphate, 20% cupric chloride, dilute nitric acid, and ammonia (*d* 0·880) gave none.

The System Magnesium Hydroxide–Gelatin.

The periodic structure produced when ammonia diffuses into a gelatin gel containing magnesium chloride has been described by Popp (*Kolloid-Z.*, 1925, **36**, 208), and the system is unique in that it produces only a small number of sharply defined, relatively massive bands.

For coagulation experiments, a 6·5% gelatin gel was used, containing 5% of crystallised magnesium chloride with an equivalent amount of ammonia. The magnesium hydroxide remained in colloidal solution under these conditions. The mixture was allowed to set to a gel in test-tubes, and ammonia solution (*d* 0·880) was

poured over each. After 4 days, the periodic structure portrayed in Fig. 3 was produced. These rings are comparable with those produced by direct diffusion of strong ammonia into gelatin containing magnesium chloride alone. The photograph was taken by transmitted light, and the white rings of magnesium hydroxide therefore appear dark and the clear spaces white.

Chemical Analysis of the Periodic Structure.—The system magnesium hydroxide–gelatin lends itself admirably to investigation by means of chemical analysis, as a result of the macroscopic nature of the effect. Some analyses (for which no great accuracy is claimed) were therefore undertaken with this system, the object of the examination being solely to determine whether a very uneven distribution of material between the bands and spaces occurs, or whether these approximate to each other in composition. It has often been supposed that the actual amount of product in equal volumes of the bands and the clear spaces is in many cases nearly equal (compare Hatschek, *British Association, Second Colloid Report*, 1918), but the results of the present analysis show that the composition of the bands differs widely from that of the clear space.

According to Ostwald (*Kolloid-Z.*, 1925, **36**, 380), Popp carried out some analyses of the system under discussion, and found the concentration of chlorine ions in the bands directly after formation to be almost double that in the original gel, but experimental details were not given. We reproduce our results, since they not only differ quantitatively from those of Popp, but are in the opposite sense. The divergence is probably to be explained by the fact that, whereas the determinations reported by Ostwald were made on new-born rings, those now given refer to the completed structure a week or more old. The structures were prepared by diffusing ammonia (*d* 0·880) into 7·5% gelatin gel containing 5% of crystallised magnesium chloride. Such a concentration of gel was necessary to secure rigidity in cutting and handling, although Popp recommends a 3% gel for giving the best bands.

The following device for removing the gels from the tubes was found eminently satisfactory. After excess of the diffusing liquid had been poured away, a groove was cut by means of a glass knife so as to encircle completely the tube near the lower, closed end. The end of the tube could be removed as a cap by applying a red-hot splinter of glass to the groove. The tube was then dipped for 1 second into water at about 80°, which had the effect of loosening the gelatin adhering to the glass, and the entire structure could readily be blown out of the tube. All other methods of extricating the gels failed because of the strong adherence of gelatin to glass. Agar gels can conveniently be removed by cracking open the tubes.

The structures were cut up into bands and clear spaces by means of a safety-razor blade.

The white bands were found to be fairly hard and relatively heavy (the density was about 1·7 times that of the clear space), and were readily detached in the form of pastilles from the intervening gel spaces. Three bands and the two enclosed clear spaces were chosen for the analysis. In order to gain an indication of the distribution of material in equal volumes of band and space as well as in equal weights, the length of gel taken was measured in addition to the weight. The error of measurement of the length was great, however, and much more trust may be placed upon the results expressed per unit weight of gel.

Determination of magnesium. The method was to heat the gel gently in a platinum crucible until water had ceased to be driven off, and later over the blowpipe until a constant weight of magnesium oxide was obtained. In the meantime, the ammonium chloride volatilised. The weight of gelatin ash was subtracted from the total weight. Slight alterations due to differences in swelling, etc., may be disregarded. The results are summarised in the following table :

Determination of MgO (structure 7 days old).

	Length of gel (mm.).	Wt. of gel (g.).	Wt. of MgO.	G. of MgO per mm.	G. of MgO per g. of gel.	Relative amounts of MgO, per unit vol.	Relative amounts of MgO, per unit wt.
Band	5	1·47	0·046	0·009	0·031	20	12
Clear space	20	3·51	0·009	0·00045	0·0026	1	1

Determination of chloride. The gel was made up to 100 c.c. by addition of dilute nitric acid. Direct titration with silver nitrate and potassium thiocyanate yielded poor results, as the end-point was changed by the presence of the gelatin. A method similar to that used for the determination of chlorides in blood was therefore adopted. The gelatin was precipitated by means of tungstic acid, and after filtration, silver nitrate and nitric acid were added in excess, and portions of the solution were titrated with standardised potassium thiocyanate. A good end-point was obtained with the solution from the clear space, but that from the bands gave a poor end-point. The following table contains the results :

Determination of chloride (structure 9 days old).

	Length of gel (mm.).	Wt. of gel (g.).	Total chloride.	G. of chloride per mm.	G. of chloride per g. gel.	Relative amounts of chloride per unit vol.	Relative amounts of chloride per unit wt.
Band	7	1·543	0·0060	0·00086	0·0039	1·0	1·0
Clear space	26	4·240	0·054	0·00207	0·0127	2·4	3·26

The analyses show that the amount of precipitate contained in the bands is 12 times as great as that present in an equal weight of clear space, whereas the chloride content of the bands is less than one-third of that of the clear space. The equivalent ratio, $\frac{1}{2}$Mg : Cl, is 14·0 : 1 in the bands, and 1 : 2·8 in the clear space.

It may be observed that the total chloride in the gel is not equivalent to the total magnesium. The missing chloride was found in the diffusing solution standing above the gel, indicating that the soluble product, ammonium chloride, diffuses out of the gel and into the ammonia solution. Experiments were therefore conducted in which this outward diffusion was prevented by dissolving in the diffusing ammonia solution sufficient ammonium chloride to give a concentration just equal to that produced in the gel by reaction. Excellent bands developed in these tubes, so that the outward diffusion of ammonium chloride is not essential to the production of the periodic structure.

Other experiments were carried out, in which equivalent solutions of magnesium chloride and ammonia were mixed in 7·5% gelatin, and water was placed over the gel, in order to see whether, with the outward diffusion of the ammonium chloride, the magnesium hydroxide would be precipitated in bands; but no precipitate was formed.

The "diffusion-wave" theory of Wo. Ostwald (*loc. cit.*) is founded largely on observations on the magnesium hydroxide system. The theory is admitted to be applicable only to rhythmic structures produced by chemical reaction, and the existence of three diffusion waves (those of the two reacting substances and of the soluble product) is postulated. Since the work described in the present paper has shown that essentially similar structures can be produced after the chemical reaction is completed, it would seem that the theory is not very comprehensive. An instance where the diffusion-wave theory appears to fail completely is in the production of rhythmic structures by potassium iodide or lead nitrate diffusing into lead iodide in agar. Here, the greatest possible number of diffusion waves which can be set up is two, and yet the resulting structure does not differ from that produced as the result of chemical interaction of lead nitrate and potassium iodide.

The Periodic Coagulation of Sols of Arsenious Sulphide and Ferric Hydroxide.

As a corollary to the experiments on the production of periodic structures after the chemical reaction has been carried out, it should be possible to obtain such structures by simple diffusion of

a coagulating electrolyte into a sol contained in a gelatin or agar gel. Experiments have been conducted on these lines with sols of arsenious sulphide and of ferric hydroxide in agar gels.

An arsenious sulphide sol was prepared by passing hydrogen sulphide into a solution containing 0·5 g. of sodium arsenite in 500 c.c. of water, and removing the excess of hydrogen sulphide by means of a stream of hydrogen. Three gels containing different amounts of arsenious sulphide were prepared. Gel 1 was made by mixing the arsenious sulphide sol with an equal volume of 2% agar sol; Gel 2 was prepared by diluting the arsenious sulphide to one-half of the original concentration with water, and mixing equal volumes of the diluted sol and 2% agar; and in Gel 3 the arsenious sulphide sol was first diluted to one-fourth of its concentration and then mixed with an equal volume of 2% agar. The diffusing electrolyte was ferric chloride or aluminium sulphate at concentrations of 30, 10, 5, and 1%.

In these systems the process of diffusion was slow, and results of observations made after 20 days are given below. With ferric chloride as the diffusing agent, no bands were produced in Gel 3 for any of the concentrations, Gel 2 produced poor bands, and Gel 1 good bands. The best results were obtained with 5 and 1% of ferric chloride. The formation of the bands, therefore, is favoured by a high concentration of colloid and a low concentration of electrolyte. As shown below, a still higher concentration of arsenious sulphide sol is unfavourable to band formation, suggesting that there is an optimum concentration.

In transmitted light the periodic structure appeared as a number of dark bands across the test-tube, which were just discernible in reflected light by their deeper yellow colour. The spaces between the bands contained a considerable amount of arsenious sulphide.

The most characteristic feature of these structures is the fact that the distance between successive bands *decreases*, whereas in most periodic structures the successive bands become more widely spaced throughout the diffusion. This fact agrees with the observation that the mean distance between the bands is greater the more concentrated the diffusing solution, and is contrary to the usual observation. With 30% and 1% ferric chloride, the mean distances between the bands were respectively 9 mm. and 3 mm. One such instance of a periodic structure has been recorded (Davies, *J. Amer. Chem. Soc.*, 1917, **39**, 1312), which occurs in the precipitation of mercury when mercurous nitrate diffuses into sodium formate contained in gelatin.

The results were similar in the experiments with aluminium sulphate as the coagulating agent. Bands were observed only in

Gel 1, and the best results were obtained in the tubes containing the lower concentrations of diffusing agent. The distance between successive bands decreased, and the spacing was wider the more concentrated the solution; 10% aluminium sulphate produced 7 bands occupying 33 mm. along the tube, and 1% aluminium sulphate produced 6 bands occupying 20 mm.

To ensure that these bands were really caused by coagulation of the arsenious sulphide sol, control experiments were conducted in which the solutions were allowed to diffuse into (*a*) 1% agar gel alone, (*b*) 1% agar containing sodium sulphide equal in amount to that produced together with arsenious sulphide in the sols discussed above. No bands were produced in any of these tubes.

A further precaution was taken, in that the experiments were repeated with colloidal arsenious sulphide prepared in almost complete absence of electrolytes. 0·5 G. of arsenious oxide was added to boiling water with two drops of 2*N*-sodium hydroxide to aid the dispersion. Dissolution occurred readily and hydrogen sulphide was passed through, the excess being removed by means of hydrogen. Two concentrations of sol were prepared; in the first, equal volumes of arsenious sulphide sol and 2% agar were mixed, and in the second the arsenious sulphide sol was diluted to one-half of its original concentration with water before being mixed with an equal volume of the agar sol. The diffusing agents were ferric chloride, aluminium sulphate, and magnesium chloride at concentrations of 10, 5, 1, and 0·5%. After 12 days, good bands had formed only in the more dilute sol, especially with ferric chloride at concentrations of 0·5 and 1%. The more concentrated sol gave zonal turbidities rather than definite bands, the best examples occurring with 10% magnesium chloride and 0·5% ferric chloride and aluminium sulphate. The decreasing distance between successive bands was again noticed in these systems.

Some experiments of the same type were carried out on undialysed sols of ferric hydroxide, prepared by the ammonium carbonate method (Hatschek, "Laboratory Manual of Colloid Chemistry," 1925, p. 46). Three concentrations of sol were used, the original concentration being diluted 10, 20, and 40 times respectively. The gels were prepared by mixing equal volumes of the sols with 2% agar and allowing them to set. The coagulating electrolytes used were 30% and 10% sodium sulphate, 20% and 5% sodium arsenite, and 20% and 5% ammonium carbonate. After 13 days, periodic structures had appeared only in the tubes containing the sol of middle concentration, banded turbidities being produced when the coagulating electrolyte was 20% or 5% sodium arsenite or 5% ammonium carbonate. In the tube containing 5% sodium arsenite,

the distances between successive bands were 15, 12, 10, 9, and 7 mm., a decrease again being apparent. With 20% sodium arsenite the bands made their first appearance about half-way down the tube, showing that in this case also a dilute coagulating agent is favourable.

Anomalous Structures.

Many investigators of the Liesegang phenomenon have commented on the mal-formations sometimes produced. In many cases these are due to lack of homogeneity of the gel or of some other component of the system. It was found in the present work, for example, that deformed rings of magnesium hydroxide were produced when a crystal of ammonium chloride was dropped into the gel containing magnesium chloride. Some experiments in which 30% lead nitrate diffused into 2% potassium iodide contained in an agar gel produced rings in twins. In another experiment, equal volumes of 2% agar and 5% magnesium chloride were mixed in a test-tube and allowed to set; when ammonia (*d* 0·880) diffused in, a spiral structure of magnesium hydroxide was formed. It was observed that spiral precipitation was not caused directly by helicoid diffusion, but that layers of precipitate reaching half-way across the test-tube were formed alternately on opposite sides, and at different levels; later, these joined to form a spiral. When the bands became more than about 1 cm. apart, they no longer joined up. This effect may be caused by temperature difference due to the exposure of one side of the tube to a draught.

An extreme case of this anomaly was observed in the reverse experiment, in which 50% magnesium chloride solution diffused into a mixture of equal volumes of 2% agar and ammonia containing 5·4 c.c. (*d* 0·880) in 100 c.c.; the first band consisted of a thin disc suspended in the agar, a short way below the surface, which did not reach to the sides of the tube; it was closely followed by an annulus, the space in the middle corresponding with the disc above, as though the disc had thrown its shadow on to the second band. The ring was succeeded by another disc which in its turn was followed by a corresponding ring. The discs and rings were too close together to be photographed, but a similar experiment in which gelatin was used instead of agar is shown in Fig. 4. The disc consisted of a thick, firm pastille, and was separated some distance from its corresponding ring. The gelatin melted during a warm week-end, before any further discs and rings had formed. This type of structure may be caused by the unequal rate of setting of the gel in the middle and near the walls of the tube.

Summary.

The production of periodic structures of silver dichromate and of magnesium hydroxide in gelatin, and also of lead iodide in agar, has been studied. In each case, by mixing equivalent quantities of the reactants in the gel, and then superimposing a strong solution of the diffusing electrolyte, it has been possible to separate the chemical reaction from the formation of precipitate. Since the rings produced in these experiments are comparable with those produced by chemical reaction, it follows that the formation of periodic structures is a coagulation phenomenon taking place after the chemical reaction. Periodic structures are to be distinguished, therefore, from periodic reactions.

The critical concentration of silver nitrate required to coagulate colloidal silver dichromate has been measured, and the results are discussed in connexion with Holker's periodic precipitation experiments.

A chemical analysis of a periodic structure of magnesium hydroxide in gelatin has been conducted, and the results show that the ratio of magnesium hydroxide contained in the bands to that in the clear spaces is about 12 : 1; the corresponding ratio for ammonium chloride is about 1 : 3.

Periodic coagulation of sols of arsenious sulphide has been effected by diffusing solutions of ferric chloride and aluminium sulphate into the sol contained in 1% agar gel, and similar results have been obtained in the coagulation of colloidal ferric hydroxide by sodium arsenite and by ammonium carbonate. In these cases, there is an optimum concentration of colloid, and band formation is favoured by a dilute diffusing electrolyte.

We are indebted to Professor J. F. Spencer for affording research facilities to one of us (R. V. H.).

CCCLXI.—*Co-ordination Compounds of Quinquevalent Molybdenum: Complex Thiocyanates.*

By ROBERT GILBERT JAMES and WILLIAM WARDLAW.

ONE of the most sensitive methods for the detection and estimation of small amounts of molybdenum is the so-called potassium thiocyanate reaction, based on the observation of Braun (*Z. anal. Chem.*, 1863, **2**, 36; 1867, **6**, 86) that a mineral acid solution of molybdenum

trioxide containing an alkali thiocyanate turns a deep red on the addition of a reducing agent such as zinc or stannous chloride. Even at the present time the constitution of the substance responsible for the red coloration is not known with certainty. It can, however, be almost quantitatively extracted from its aqueous solution by ether. Addition of pyridine or quinoline to the ethereal extract gives dark red oils which, on standing, or boiling with alcohol, yield brownish-red crystalline substances to which the formula $R_2Mo(OH)_2(CNS)_3$, where $R = C_5H_5N$ or C_9H_7N, was assigned (Rosenheim and Koss, *Z. anorg. Chem.*, 1906, **49**, 148; Sand and Burger, *Ber.*, 1906, **39**, 1761).

A more rational formulation on the basis of Werner's theory would be $R_2[MoO_2(CNS)_3]$, where $R = C_5H_6N$ or C_9H_8N, which suggests that possibly the red colour in the ethereal solution is due to the complex acid $H_2[MoO_2(CNS)_3]$. The isolation of this acid was attempted by Rosenheim and Koss (*loc. cit.*), who produced a deep red solution by boiling molybdenum trioxide with thiocyanic acid (10%) under reflux, and obtained from the filtrate by evaporation an almost black, hygroscopic residue of variable composition, but probably chiefly containing $Mo(OH)_2(CNS)_3$ (Abegg, "Handbuch," IV, 1, p. 541). By dissolving the pyridinium salt

$$(C_5H_6N)_2[MoO_2(CNS)_3]$$

in thiocyanic acid, Rosenheim and Koss obtained insoluble, dark green, rhombic crystals to which they gave the composition $Mo(OH)_2(CNS)_5H_2(C_5H_5N)_2$, which is better written as

$$(C_5H_6N)_2[MoO(CNS)_5],H_2O.$$

As the above summary indicates, our knowledge concerning thiocyanates of quinquevalent molybdenum is still far from complete, and in view of their interest in both analytical and theoretical chemistry, further investigation seemed desirable.

Salts of the Type $R_2[MoO_2(CNS)_3]$.—In the present investigation, the above method for the preparation of the complex pyridinium and quinolinium salts has been discarded in favour of the reaction between ammonium thiocyanate and salts of the type $R_2[MoOCl_5]$; Sand and Burger (*loc. cit.*) mentioned this method but gave no experimental details. In a previous communication (J., 1927, 2145) the preparation and properties of the green crystalline salts $R_2[MoOCl_5]$ were described, and it was shown from physico-chemical data that such salts undergo extensive decomposition in aqueous solution. Qualitative evidence of this decomposition is seen in the fact that these green salts dissolve in water giving brown acidic solutions from which it is impossible satisfactorily to obtain the original salt by recrystallisation. It is not unexpected, therefore, that in aqueous solution the reaction between ammonium thiocyanate and complex

salts of the type $R_2[MoOCl_5]$ does not give products in accordance with the equation: $5NH_4CNS + R_2[MoOCl_5] = R_2[MoO(CNS)_5] + 5NH_4Cl$, but yields instead insoluble substances of the type $R_2[MoO_2(CNS)_3]$. As shown later, salts of the type $R_2[MoO(CNS)_5]$ can only be produced in presence of excess of thiocyanic acid.

The formation of the compounds $R_2[MoO_2(CNS)_3]$ is additional evidence for the scheme of ionisation and hydrolysis mentioned in our previous communication:

$$R_2[MoOCl_5] + H_2O \rightleftharpoons R[MoOCl_4,H_2O] + RCl \quad . \quad (1)$$

$$R[MoOCl_4,H_2O] + H_2O \rightleftharpoons [MoOCl_3,2H_2O] + RCl \quad . \quad (2)$$

$$[MoOCl_3,2H_2O] + H_2O \rightleftharpoons [MoO(OH)Cl_2,2H_2O] + HCl \quad (3)$$

$$[MoO(OH)Cl_2,2H_2O] + H_2O \rightleftharpoons [MoO(OH)_2Cl,2H_2O] + HCl$$
$$\rightleftharpoons [MoO_2Cl,3H_2O] + HCl \quad . \quad . \quad (4)$$

$$[MoO_2Cl,3H_2O] + H_2O \rightleftharpoons [MoO_2OH,3H_2O] + HCl \quad . \quad (5)$$

When stage (4) is reached, in all probability the reaction in the presence of ammonium thiocyanate takes the following course:

$$[MoO_2Cl,3H_2O] + NH_4CNS \longrightarrow [MoO_2CNS,3H_2O] + NH_4Cl$$
$$2RCl + 2NH_4CNS \longrightarrow 2RCNS + 2NH_4Cl$$
$$2RCNS + [MoO_2CNS,3H_2O] \longrightarrow R_2[MoO_2(CNS)_3] + 3H_2O$$

In this way complex thiocyanates, where R = C_9H_8N, C_5H_6N, or Tl (ous), have been prepared.

The reaction between aqueous solutions of $(NH_4)_2[MoOCl_5]$ and ammonium thiocyanate may be expressed as follows:

$$[NH_4]_2[MoOCl_5] + 4H_2O \rightleftharpoons [MoO_2Cl,3H_2O] + 2NH_4Cl + 2HCl$$
$$2HCl + MoO_2Cl + 3NH_4CNS \rightleftharpoons H_2[MoO_2(CNS)_3] + 3NH_4Cl.$$

The *dihydrogen molybdenum dioxytrithiocyanate* has been thus prepared. It is extremely deliquescent, and exhibits a green lustre. A concentrated aqueous solution is purple-red, but on further dilution becomes red, orange, and finally yellow. The concentrated solutions yield purple precipitates with nitrates of silver and thallium, but the dilute yellow solutions give almost white precipitates consisting chiefly of thallous or silver thiocyanate. These reactions indicate that whilst in concentrated aqueous solution a complex acid is present, on dilution the complex anion undergoes hydrolysis and further ionisation.

Salts of the Type $R_4[Mo_2O_3(CNS)_8]$.—In view of the production of salts of the foregoing type, it was interesting to discover that when the green salts $[(CH_3)_3NH]_2MoOCl_5$ and $[(CH_3)_4N]_2MoOCl_5$ reacted with ammonium thiocyanate, the products were not reddish-brown compounds like the pyridinium and quinolinium derivatives

of the type $R_2[MoO_2(CNS)_3]$, but purple crystalline *substances* of the empirical formula $R_4[Mo_2O_3(CNS)_8]$. These octathiocyanates may be conveniently considered as bridge compounds having the constitution

$$R_4\left[\begin{matrix}(CNS)_3\\O\end{matrix}\!\!>\!Mo\!<\!\!\begin{matrix}O\\CNS\end{matrix}\!\!>\!\!\begin{matrix}O\\CNS\end{matrix}\!<\!Mo\!<\!\!\begin{matrix}(CNS)_3\\O\end{matrix}\right]$$

The basis for such a configuration will be demonstrated later.

Salts of the Type $R_2[MoO(CNS)_5]$.—Rosenheim and Koss (*loc. cit.*), who first discovered this series, describe the preparation of the one known derivative as follows: "When $(C_5H_5N)_2Mo(OH)_2(CNS)_3$ is dissolved in thiocyanic acid, or pyridinium thiocyanate is added directly to a solution of molybdic acid in aqueous thiocyanic acid, black, glittering, rhombic needles are obtained which are decomposed by water and dissolve in alcohol and in chloroform with a deep red colour." The composition $(C_5H_5N)_2H_2Mo(OH)_2(CNS)_5$ was ascribed to the crystals.

The above method was investigated, and after a suitable way of preparing thiocyanic acid had been established, a *pyridinium* compound was obtained of the composition $(C_5H_6N)_2[MoO(CNS)_5]$.

Quinolinium, tetramethyl- and *trimethyl-ammonium* salts of this type were also isolated, entirely analogous in formulation to the green complex chlorides $R_2[MoOCl_5]$. In their properties, however, salts of the two series exhibited marked contrasts; whilst the chlorides readily dissolved in water with considerable decomposition (the probable cause of their high solubility), the corresponding black thiocyanates were almost insoluble. In carefully dried alcohol the thiocyanates dissolved very readily, whereas the corresponding complex chlorides were almost insoluble in the cold. The formation of pentathiocyanates by the method described above takes place as follows:

$$[MoO_2(CNS)_3]R_2 + 2HCNS = [MoO(CNS)_5]R_2 + H_2O.$$

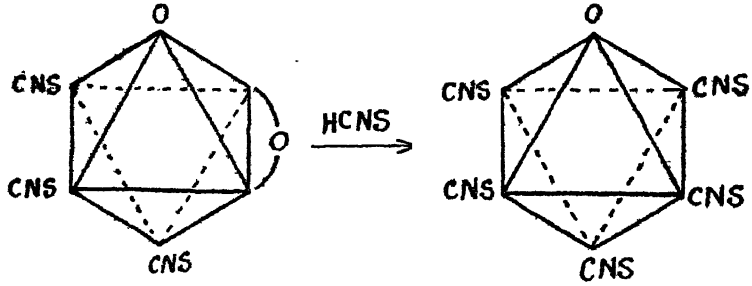
They can also be prepared by addition of the green chlorides to a boiling solution of thiocyanic acid, the thiocyanate crystallising immediately on cooling:

$$R_2[MoOCl_5] + 5HCNS \rightleftharpoons R_2[MoO(CNS)_5] + 5HCl.$$

This is a reversible reaction, for by treating the thiocyanate with hot concentrated hydrochloric acid, it is possible to obtain the pentachloride.

The preparation of the ditrimethylammonium and ditetramethylammonium members of the pentathiocyanate series involves the action of thiocyanic acid on the corresponding octathiocyanates,

and is therefore of special interest. The reaction can be represented as follows:



$$R_4\left[\begin{matrix}(CNS)_3Mo \\ O\end{matrix}\!\!<\!\!\begin{matrix}CNS \\ CNS\end{matrix}\!\!>\!\!Mo\begin{matrix}(CNS)_3 \\ O\end{matrix}\right] + 2HCNS$$

$$2R_4\left[\begin{matrix}(CNS)_3Mo\begin{matrix}CNS \\ CNS\end{matrix} \\ O\end{matrix}\right] + H_2O$$

and also seems to indicate that the octathiocyanates possess a symmetrical structure.

The Co-ordination Number of Oxygen.

In a previous communication (J., 1927, 1087) it was mentioned that oxygen, contrary to the view of Werner, did not always occupy only one position in the co-ordination sphere, but that cases did arise in which this bivalent atom must be assigned two positions. A possible illustration of this fact is afforded by the co-ordination compounds of quinquevalent molybdenum. In the complex salts $R_2[MoOCl_5]$ and $R_2[MoO(CNS)_5]$, with oxygen occupying only one position in the co-ordination sphere, the molybdenum has a co-ordination number of six. With related complex substances of the type $R_2[MoO_2(CNS)_3]$ Werner's conclusions would lead to the molybdenum atom being assigned a co-ordination number of five. However, by the action of thiocyanic acid it is a simple matter to transform a salt of the type $R_2[MoO_2(CNS)_3]$ into the type $R_2[MoO(CNS)_5]$, where the molybdenum atom has a co-ordination number of six. It seems questionable whether this reaction involves the change of a five-point into a six-point system, and a more rational formulation would be to assign in both cases a co-ordination number of six to the molybdenum atom. It would then be necessary to consider one oxygen as occupying one position, and the other two positions, in the co-ordination sphere.

Such a configuration clearly demonstrates why one oxygen is reactive, and the other is not. It is also a matter of interest to find that neither in the case of the complex chlorides $R_2[MoOCl_5]$ nor in

that of the corresponding thiocyanates $R_2[MoO(CNS)_5]$ can the oxygen atom be displaced by the highest concentration of acid with the formation of such salts as $R_2[MoCl_7]$ or $R[MoCl_6]$.

It must be noted, however, that salts of the type $R_2[MoO_2(CNS)_3]$ may be represented as $R_4\left[\begin{matrix}(CNS)_3\\O\end{matrix}Mo\begin{matrix}O\\O\end{matrix}Mo\begin{matrix}(CNS)_3\\O\end{matrix}\right]$.

In a previous communication the importance of the effective atomic number of the molybdenum atom in determining the stability of its complex salts was emphasised. With the spatial configuration shown in the above diagram it will be seen that in salts of the type $R_2[MoO(CNS)_5]$ and $R_2[MoO_2(CNS)_3]$ the effective atomic number is 49. It is not surprising, therefore, that in aqueous solution these salts exhibit instability, in marked contrast to the great stability of the series $R_4Mo(CN)_8$, where the effective atomic number of the central atom is 54—that of the next inert gas.

Experimental.

Compounds of the Type $R_2[MoO_2(CNS)_3]$.

The green salts of the type $R_2[MoOCl_5]$ used in the following preparations were made by methods already detailed (J., 1927, 2145).

Dipyridinium Molybdenum Dioxytrithiocyanate.—10 C.c. of warm ammonium thiocyanate solution (containing 2·3 g.) were added to 30 c.c. of a warm, constantly stirred solution containing 4·5 g. of the salt $(C_5H_6N)_2[MoOCl_5]$. The bright reddish-brown crystals thus precipitated were washed with cold water and dried over phosphoric oxide in a vacuum. The compound melted at 181°, was soluble in acetone, and dissolved in boiling alcohol, giving a deep red solution.

Analysis. A hot ammoniacal solution of the substance was oxidised with hydrogen peroxide, and the molybdenum precipitated as sulphide (J., 1924, **125**, 1911), ignited, and weighed as the trioxide. The thiocyanate radical was determined by precipitation as silver thiocyanate from a cold, very dilute solution of the complex salt acidified with nitric acid. Nitrogen was estimated by Dumas's method (Found: Mo, 20·8; CNS, 37·6; N, 15·1; C, 33·9; H, 3·0. Calc. for $(C_5H_6N)_2[MoO_2(CNS)_3]$: Mo, 20·8; CNS, 37·7; N, 15·2; C, 33·8; H, 2·6%).

Diquinolinium Molybdenum Dioxytrithiocyanate.—25 C.c. of a solution containing 5·6 g. of the salt $(C_9H_8N)_2[MoOCl_5],H_2O$ were slowly poured with constant stirring into 15 c.c. of a warm, aqueous ammonium thiocyanate solution (containing 2·3 g.). This method gave a high yield of brownish-red crystals, which were washed and dried as previously described; they dissolved in boiling alcohol, but

were almost insoluble in water (Found: Mo, 17·1; CNS, 31·0; N, 12·5; C, 44·7; H, 3·36. Calc. for $(C_9H_8N)_2[MoO_2(CNS)_3]$: Mo, 17·1; CNS, 31·0; N, 12·5; C, 44·8; H, 2·85%).

Apart from their low solubility in water, the above-mentioned brownish-red complex thiocyanates $R_2[MoO_2(CNS)_3]$ closely resemble the copper-red pyridinium molybdenum dioxydichloride,

$$C_5H_6N[MoO_2Cl_2,H_2O],$$

previously described by the present authors (*loc. cit.*). Alcoholic hydrogen chloride converts all these red salts to the corresponding green complex chlorides $R_2[MoOCl_5]$, whilst on standing, their dilute aqueous solutions deposit light brown insoluble precipitates.

Treatment of $C_5H_6N[MoO_2Cl_2,H_2O]$ with ammonium thiocyanate, in an attempt to prepare $C_5H_6N[MoO_2(CNS)_2,H_2O]$, resulted in brownish-red crystals containing a high proportion of

$$(C_5H_6N)_2[MoO_2(CNS)_3].$$

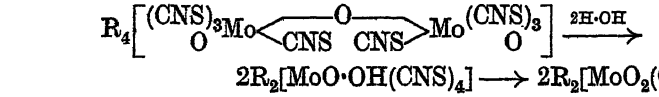
Dihydrogen Molybdenum Dioxytrithiocyanate.—Hitherto no metallic salts of the type $R_2[MoO_2(CNS)_3]$ have been prepared. However, the addition of thallous or silver nitrate solution to a concentrated purple-red, aqueous solution of what is probably the complex acid $H_2[MoO_2(CNS)_3]$ gave rich purple precipitates. It proved extremely difficult to prepare pure specimens of these insoluble salts, owing to the simultaneous precipitation of thallous or silver thiocyanate, or even chloride. It seemed desirable, therefore, to find a method of preparing the acid, free from impurities, and also to attempt to determine its composition and constitution. The following method proved very satisfactory for the preparation of *dihydrogen molybdenum dioxytrithiocyanate:* To 15 c.c. of a solution of ammonium thiocyanate (4·6 g.) at 40° contained in a tap-funnel in an atmosphere of nitrogen, there were added 6·5 g. of the salt $(NH_4)_2[MoOCl_5]$, dissolved in 25 c.c. of warm water. The deep purple-red solution thus produced was agitated with 150 c.c. of ether, and the aqueous layer drawn off as completely as possible. About 2 c.c. of water were added to the ethereal extract remaining in the funnel, the mixture was agitated, and the aqueous layer completely withdrawn. By pressure of nitrogen, the ethereal solution was filtered into a flask which was evacuated to remove the ether. The product was a deep purple-red oil. The evacuated flask was heated on a water-bath, and the purple-red oil converted into an almost black solid which was kept in a vacuum over phosphoric oxide and solid potassium hydroxide (Found: Mo, 27·7; CNS, 52·5. Mo : CNS = 1 : 3·13. $H_2[MoO_2(CNS)_3],2H_2O$ requires Mo, 28·2; CNS, 51·2%). A solid of similar composition was obtained by keeping the oil for a long time over concentrated sulphuric acid.

In a modification of this method in which the flask containing the

solidified oil was connected with another flask containing concentrated sulphuric acid and the whole kept as highly evacuated as possible for a day, the solid *anhydrous acid* was obtained (Found : Mo, 31·2; CNS, 55·3; N, 14·3; Mo : CNS : N = 1 : 2·93 : 3·13. $H_2[MoO_2(CNS)_3]$ requires Mo, 31·6; CNS, 57·2; N, 13·8%).

Preparation of Dithallous Molybdenum Dioxytrithiocyanate.—The purple-red oil obtained as described above was mixed with 50 c.c. of water (the total volume of the mixture being *ca.* 55 c.c.), the solution warmed to 30°, and poured slowly with constant stirring into 50 c.c. of a saturated solution of thallous nitrate at 30°. The bluish-purple precipitate after being washed with water was dried in a vacuum over phosphoric oxide.

Analysis. To a weighed amount of the substance mixed with water, concentrated hydrochloric acid was added immediately with stirring, whereby the complex salt was partly decomposed with liberation of the free acid. The solution was now boiled to complete the decomposition of the salt. Some thallous chloride was precipitated, but with further dilution and boiling the precipitated chloride was wholly dissolved. To this boiling solution a slight excess of potassium iodide solution was added, and the precipitated thallium iodide was washed with very dilute potassium iodide solution, and finally with aqueous alcohol, and dried at 130—140°. The filtrate and washings were raised to boiling, treated with hydrogen peroxide, and the liberated iodine was boiled off. The resulting solution was made ammoniacal, boiled, and oxidised with more hydrogen peroxide until colourless, the molybdenum then being determined in the usual way (Found, for two samples : Mo, 13·4, 13·1; Tl, 55·9, 56·6; CNS, 24·0, 25·0; N, 6·0, 6·0. $Tl_2[MoO_2(CNS)_3,H_2O]$ requires Mo, 13·2; Tl, 56·0; CNS, 23·9; N, 5·8%).



The composition of this *thallium* salt varied slightly with variations in the method of preparation. For example, it is essential to pour the warmed purple-red solution of the complex acid into the thallium nitrate solution, and not *vice versa*. Moreover, the preparation of the purple-red solution must be carefully carried out in order to avoid oxidation or contamination with thiocyanic or hydrochloric acid.

Salts of the Type $R_4[Mo_2O_3(CNS)_8]$.

The preparations of the three substituted ammonium molybdenyl pentachlorides used below are described later (p. 2737).

Tetra-trimethylammonium Dimolybdenum Trioxyoctathiocyanate.—A solution of 4 g. of $[(CH_3)_3NH]_2[MoOCl_5],H_2O$ in 10 c.c. of water was poured into 10 c.c. of a warm, constantly stirred, aqueous solution of ammonium thiocyanate (3·1 g.). The copious purple crystalline precipitate was washed with water and dried in a vacuum

over phosphoric oxide (Found: Mo, 20·3, 20·35; CNS, 49·1; N, 17·9; C, 25·2; H, 4·25. $[(CH_3)_3NH]_4[Mo_2O_3(CNS)_8]$ requires Mo, 20·3; CNS, 49·2; N, 17·8; C, 25·4; H, 4·24%); it exhibits a green lustre and leaves a bluish-purple streak on unglazed porcelain. It is sparingly soluble in cold water, but more soluble in hot, owing to hydrolysis. Concentrated solutions are purple, but on dilution turn blood-red, then orange, and finally bright yellow. An interesting reaction of this complex thiocyanate is its decomposition with thallous nitrate: To a warm, blood-red, saturated solution of the octathiocyanate, there was added, drop by drop, a saturated aqueous solution of thallous nitrate. A purple or reddish-purple precipitate was obtained if care was taken to add insufficient thallous nitrate for complete precipitation, which was shown by the supernatant liquid remaining reddish-orange. After washing and drying in a vacuum over phosphoric oxide, this precipitate gave Mo, 12·8; Tl, 58·1; CNS, 24·1; Tl : CNS = 2 : 2·93, showing it to be an impure specimen of $Tl_2[MoO_2(CNS)_3,H_2O]$. The isolation of this thallium derivative indicates that the octathiocyanate undergoes hydrolysis in solution in such a way as to indicate a symmetrical structure for the octathiocyanate

$$2R_2[MoO{\cdot}OH(CNS)_4] \longrightarrow 2R_2[MoO_2(CNS)_3] + 2HCNS.$$

The action of thiocyanic acid on the octathiocyanate furnishes additional evidence in favour of the above configuration.

Tetra-tetramethylammonium Dimolybdenum Trioxyoctathiocyanate.—Into 10 c.c. of a warm aqueous solution of ammonium thiocyanate (2·8 g.), there were slowly poured with constant stirring 10 c.c. of a solution containing 4 g. of $[(CH_3)_4N]_2MoOCl_5$. An excellent yield of a magenta salt was obtained, which was washed with water and dried in a vacuum over phosphoric oxide (Found: Mo, 19·3; CNS, 46·6; N, 16·9; C, 28·7; H, 4·92. $[(CH_3)_4N]_4[Mo_2O_3(CNS)_8]$ requires Mo, 19·2; CNS, 46·5; N, 16·8; C, 28·8; H, 4·80%). On standing, the filtrate deposited bluish-purple crystals, exhibiting a green lustre, which had the same empirical composition as the first yield (Found: Mo, 19·25; CNS, 46·6; N, 16·6%). The properties of this second complex octathiocyanate resemble those of the trimethylammonium analogue.

In order to determine whether a similar octathiocyanate could be obtained with the diethylammonium derivative, the salt $[(C_2H_5)_2NH_2]_2MoOCl_5$ was prepared, and its reaction with ammonium thiocyanate studied. It was found that an oil resulted from which no crystalline substance could be isolated.

Tetrapyridinium Dimolybdenum Trioxysulphatohexathiocyanate.—By treating the reddish-brown thiocyanate, previously formulated as $(C_5H_5N)_2Mo(OH)_2(CNS)_3$, with sulphuric acid, Sand and Burger (*loc. cit.*) obtained from the resulting deep purple-red solution dark green needles, to which they assigned the formula

$$Mo(OH)(SO_4)_{\frac{1}{2}}(CNS)_3(C_5H_5N)_2,$$

basing their deductions on the following analysis :

	Mo.	N.	Total S.	S as SO_4.
Calc.	19·47	14·19	22·72	3·25
Found	19·17	13·66	23·01	3·01

By repeating this experiment, with slight modifications, we have isolated a purple compound which appears to have the configuration

$$(C_5H_6N)_4\left[\begin{matrix}(CNS)_3\\O\end{matrix}{}^{3}Mo\begin{matrix}<O\\<SO_4>\end{matrix}Mo\begin{matrix}(CNS)_3\\O\end{matrix}\right]$$

in which a relationship to the octathiocyanates

$$R_4\left[\begin{matrix}(CNS)_3\\O\end{matrix}{}^{3}Mo\begin{matrix}<\text{——}O\text{——}\\<CNS\ \ CNS>\end{matrix}Mo\begin{matrix}(CNS)_3\\O\end{matrix}\right]$$

is readily apparent. Although the colour of this substance differs from that of the salt obtained by Sand and Burger, the two compounds are probably identical, for the analytical figures obtained by Sand and Burger for their substance agree very closely with those demanded by the formula ascribed to the purple compound.

Preparation. 9·0 G. of $(C_5H_6N)_2[MoOCl_5]$ in 40 c.c. of water were added to 25 c.c. of a warm solution containing ammonium thiocyanate (4·6 g.), and the precipitated thiocyanate

$$(C_5H_6N)_2[MoO_2(CNS)_3]$$

was dried, finely powdered, and treated with 150 c.c. of sulphuric acid (5*N*). On warming, a deep red solution resulted, and crystals gradually appeared on the surface of the liquid. Further warming caused the crystals to revert to a black oil, which later began to bubble. At this stage the well-shaken mixture was rapidly filtered, and the filtrate cooled, finally by ice-cold water. The crystals obtained were washed with sulphuric acid (5*N*), then with absolute alcohol, and finally dried in a vacuum over calcium chloride (Found : Mo, 19·1; CNS, 35·0; N, 13·9; SO_4, 9·72; C, 31·1; H, 2·50. Calc. for $(C_5H_6N)_4[Mo_2O_3(SO_4)(CNS)_6]$: Mo, 19·1; CNS, 34·7; N, 13·9; SO_4, 9·56; C, 31·1; H, 2·39%).

Properties. The bright purple crystalline compound was almost insoluble in alcohol, and sparingly soluble in cold water, but on continued contact the crystals slowly dissolved, producing a brown solution changing to yellow on dilution. If the action of sulphuric acid was continued beyond the stage specified above, dark brown,

crystalline substances were produced (Found: Mo : N = 1 : 9 and Mo : CNS : N = 1 : 2 : 4). It appears probable that in these compounds some of the thiocyanate groups in the original purple salt have been replaced by sulphate equivalents.

Inconclusive results were obtained from the action of hydrochloric acid on $(C_5H_6N)_2[MoO_2(CNS)_3]$ and of sulphuric and hydrochloric acids on $(C_9H_8N)_2[MoO_2(CNS)_3]$.

Salts of the Type $R_2[MoO(CNS)_5]$.

Thiocyanic Acid Solution.—To 200 c.c. of a well-cooled solution of potassium thiocyanate (100 g.), 180 c.c. of sulphuric acid (5*N*) were slowly added with constant stirring, and the mixture was distilled in a vacuum, the distillate (*ca.* 200 c.c.) being collected in a well-cooled receiver. As a yellow substance separates on standing or prolonged boiling, freshly distilled acid was used in the following experiments.

Dipyridinium Molybdenyl Pentathiocyanate.—Dipyridinium molybdenum dioxytrithiocyanate (4·0 g.) was added to 150 c.c. of boiling thiocyanic acid, the solution rapidly filtered, and the filtrate cooled in ice. The crystals obtained were washed with cold thiocyanic acid solution, and dried in a vacuum over solid potassium hydroxide and phosphoric oxide. The compound was greenish-black in colour, and made a red mark on unglazed porcelain (Found: Mo, 17·1; CNS, 51·7; N, 17·4; C, 31·8; H, 2·28. $(C_5H_6N)_2[MoO(CNS)_5]$ requires Mo, 17·1; CNS, 51·7; N, 17·4; C, 32·0; H, 2·14%).

Diquinolinium Molybdenyl Pentathiocyanate.—This was prepared as above from the corresponding diquinolinium salt (5·0 g.) and thiocyanic acid (180 c.c.), greenish-black crystals being obtained (Found: Mo, 14·5; N, 14·9; C, 41·7; H, 2·49.

$(C_9H_8N)_2[MoO(CNS)_5]$

requires Mo, 14·5; N, 14·8; C, 41·7; H, 2·42%).

Ditrimethylammonium Molybdenyl Pentathiocyanate.—Tetratrimethylammonium dimolybdenum trioxyoctathiocyanate, prepared from 4 g. of $[(CH_3)_3NH]_2[MoOCl_5],H_2O$, was treated as before with 75 c.c. of thiocyanic acid solution and yielded greenish-black crystals of the required *compound* (Found: Mo, 18·5; CNS, 55·7; N, 18·8; C, 25·1; H, 4·03. $[(CH_3)_3NH]_2[MoO(CNS)_5]$ requires Mo, 18·4; CNS, 55·6; N, 18·8; C, 25·25; H, 3·83%).

Ditetramethylammonium Molybdenyl Pentathiocyanate.—3·0 G. of $[(CH_3)_4N]_2MoOCl_5$ were converted into the octathiocyanate. The finely powdered product was treated with thiocyanic acid (100 c.c.), whereupon reddish-brown crystals separated, which were very sparingly soluble in water, but more soluble in alcohol and chloroform (Found: Mo, 16·96; N, 17·34; C, 27·75; H, 4·59.

$[(CH_3)_4N]_2[MoO(CNS)_5],H_2O$

requires Mo, 16·89; N, 17·26; C, 27·45; H, 4·58%). Treatment with aqueous alcohol gave a magenta-coloured precipitate, which was probably the octathiocyanate regenerated by hydrolysis.

Salts of the Type $R_2[MoOCl_5]$.

For the preparation and investigation of the octathiocyanates previously described, the following complex molybdenyl pentachlorides were required. The preparations detailed below, involving electrolytic reduction and the use of alcoholic hydrogen chloride, differ from the method employed by Nordenskjold (*Ber.*, 1901, **34**, 1572), and give high yields of the pure salt.

Ditrimethylammonium Molybdenyl Pentachloride.—This salt was prepared by an alternative method to that previously described (J., 1927, 2148). To 100 c.c. of a boiling solution of quinquevalent molybdenum (10 g. Mo) in alcoholic hydrogen chloride, obtained as described under dipyridinium molybdenyl pentachloride (*loc. cit.*), there was added trimethylammonium chloride (16 g.). The well-stirred mixture was boiled until clear, and yielded yellowish-green needles, which were recrystallised from alcoholic hydrogen chloride and dried over potassium hydroxide and phosphoric oxide in a vacuum (Found: Mo, 22·6; Cl, 41·7; N, 6·59; C, 17·0; H, 5·10. Calc. for $[(CH_3)_3NH]_2[MoOCl_5],H_2O$: Mo, 22·5; Cl, 41·5; N, 6·56; C, 16·9; H, 5·15%).

Bisdiethylammonium Molybdenyl Pentachloride.—This was prepared as detailed above, except that diethylamine (13 g.) was used, the resulting solution being evaporated under diminished pressure. On re-saturation with hydrogen chloride, a large yield of green needles was obtained; these were washed with alcoholic hydrogen chloride and dried as before (Found: Mo, 21·9; Cl, 40·5; N, 6·40; C, 21·9; H, 5·65. $[(C_2H_5)_2NH_2]_2[MoOCl_5]$ requires Mo, 22·0; Cl, 40·5; N, 6·20; C, 22·0; H, 5·49%).

Ditetramethylammonium Molybdenyl Pentachloride.—An interesting point in connexion with the preparation of this salt is that by a variation in the proportions of the reactants it is possible to isolate a salt of the type $R[MoOCl_4,H_2O]$, of which so far only one other example is known, *viz.*, $(CH_3)_3NH[MoOCl_4,H_2O]$, previously described by the present authors. 50 C.c. of an alcoholic hydrogen chloride solution of quinquevalent molybdenum (6·4 g.) were diluted with an equal volume of alcohol, raised to boiling, and tetramethylammonium chloride (10 g.) added. The resulting light green crystals were dissolved in 200 c.c. of hydrochloric acid (4*N*), the solution saturated with hydrogen chloride, and on evaporation and re-saturation with this gas, crops of crystals were obtained. The first yields consisted of the *pentachloride*, whilst the last fraction[illegible]

to be pure *monotetramethylammonium molybdenyl tetrachloride*. The salts were recrystallised, if necessary, and dried as previously described (Found, for pentachloride: Mo, 21·9; Cl, 40·4; N, 6·4. $[(CH_3)_4N]_2MoOCl_5$ requires Mo, 22·0; Cl, 40·5; N, 6·4%. Found, for tetrachloride: Mo, 27·70, 27·60; Cl, 41·15, 41·31; N, 4·04. $(CH_3)_4N[MoOCl_4,H_2O]$ requires Mo, 27·76; Cl, 41·0; N, 4·05%).

Physico-chemical Measurements.

Throughout this communication the various complex salts have been formulated in accordance with the principles of Werner's co-ordination theory. Indirect evidence for such a formulation is obtained from the method of preparation of the salts and from their reactions, but confirmation may be obtained from determinations of molecular weights and molecular conductivities. The slight solubility of the complex salts in cold water, and their decomposition by hot water, renders determinations of molecular weight unsatisfactory by either cryoscopic or ebullioscopic methods in air-free water. However, molecular conductivities were determined at 25°:

	$(C_5H_6N)_2[MoO_2(CNS)_3]$.				$(C_9H_8N)_2[MoO_2(CNS)_3]$.			
v	262·8	525·6	1051	2102	1090	2180	4360	
μ	492	534	559	591	571	604	640	
	$[(CH_3)_2NH]_4[Mo_2O_3(CNS)_6]$.				$[(CH_3)_4N]_4[Mo_2O_3(CNS)_6]$.			
v	736·3	2945	5890	11,781	882·6	3530	7061	14,122
μ	1614	1860	1900	1960	1711	1871	1942	2036

	$(C_5H_6N)_4[Mo_2O_3(SO_4)(CNS)_6]$.				
v	623·9	1248	2496	4991	9982
μ	1504	1713	1820	1930	2010

	$(C_5H_6N)_2[MoO(CNS)_5]$.				$[(CH_3)_2NH]_2[MoO(CNS)_5]$.			
v	441	1764	3529	7058	422	1688	3376	6752
μ	1089	1286	1314	1360	1069	1272	1305	1324

It is clear from the appended figures that in no case do the complex salts behave in aqueous solution as typical electrolytes, but exhibit abnormally high molecular conductivities. Such behaviour is not unexpected in view of the series of colour changes which aqueous solutions of the salts undergo with increasing dilution. According to our views on hydrolysis and ionisation, at infinite dilution salts of the type $R_2[MoO_2(CNS)_3]$ should give undissociated $[MoO_2OH,2H_2O]$ together with six ions, *viz.*, $2R^{\cdot} + H^{\cdot} + 3CNS'$. The ionic velocities at 25° are $H^{\cdot} = 347$; $CNS' = 65{\cdot}4$ (Landolt–Börnstein, "Tabellen," 1923, ii, 1104); $C_5H_6N^{\cdot} = 43{\cdot}1$ (Lundén, *J. Chim. physique*, 1907, 5, 592); $C_9H_8N^{\cdot} = 35{\cdot}1$; $(CH_3)_2NH^{\cdot} = 47{\cdot}0$; $(CH_3)_4N^{\cdot} = 43{\cdot}6$ (Bredig, *Z. physikal. Chem.*, 1894, **13**, 228). If the proposed scheme is correct the pyridinium

salt should give a value for $\mu_{\infty}^{25°}$ of 629, which is in good agreement with the experimental values. It is interesting to find that Sand and Burger, in determining the molecular conductivity of this salt, obtained $\mu = 564$ and 613 for $v = 700$ and 2803 respectively, and concluded that the substance behaved abnormally, although no explanation was advanced. A scheme for the ionisation and hydrolysis of salts of the type $R_2[MoO(CNS)_5]$, identical with that previously recorded for the complex salts $R_2[MoOCl_5]$ (*loc. cit.*), would result in the ions $2R^{\cdot} + 3H^{\cdot} + 5CNS'$ being present at infinite dilution in aqueous solution. This should give, for

$$(C_5H_6N)_2[MoO(CNS)_5]$$

$\mu_{\infty} = 1454$, and for $[(CH_3)_3NH]_2[MoO(CNS)_5]$ $\mu_{\infty} = 1462$. The close agreement between the experimental and theoretical values lends strong support to the view that the scheme of hydrolysis and ionisation is substantially correct. A similar scheme for the complex salts of the new type $R_4[Mo_2O_3(CNS)_8]$ would be $R_4[Mo_2O_3(CNS)_8] + H_2O = 2R_2[MoO_2(CNS)_3] + 2HCNS$, followed by the further hydrolysis and ionisation of the complex salt as before, whence there should result at infinite dilution the ions $4R^{\cdot} + 4H^{\cdot} + 8CNS'$. Where $R^{\cdot} = (CH_3)_3NH^{\cdot}$, the calculated value for $\mu_{\infty} = 2099$, and where $R^{\cdot} = (CH_3)_4N^{\cdot}$, $\mu_{\infty} = 2086$ at 25°. Similarly, for the complex salt $(C_5H_6N)_4[Mo_2O_3(SO_4)(CNS)_6]$, the presence of the ions $4C_5H_6N^{\cdot} + 4H^{\cdot} + SO_4'' + 6CNS'$ in solution at 25° would give a calculated value for μ_{∞} of 2111. Again the agreement between the theoretical and experimental results is very satisfactory and therefore the formulation of these series of salts on the basis of the co-ordination theory seems to afford a satisfactory explanation of their behaviour in aqueous solution.

The authors wish to express their thanks to the Department of Scientific and Industrial Research for a grant to one of them (R. G. J.), and to the Chemical Society for their grant in aid of this investigation.

CCCLXII.—*Attempted Resolution of Triethylenediaminenickel Chloride.*

By WILLIAM RALPH BUCKNALL and WILLIAM WARDLAW.

BY the resolution of the triethylenediamines of cobalt, chromium, rhodium, and iridium into their optically active antipodes, Werner (*Ber.*, 1912, **45**, 121, 865, 1228; *Helv. Chim. Acta*, 1920, **3**, 267)

advanced a brilliant proof of his theory that in these salts the associated ethylenediamine molecules are octahedrally distributed round the central metallic atom. Nevertheless, it is a matter of interest that the similarly constituted derivatives of bivalent metals such as copper, zinc, and nickel have so far remained unresolved. The idea that in these salts the units are distributed otherwise than octahedrally seems to be disproved by the *X*-ray evidence (Wyckoff, *J. Amer. Chem. Soc.*, 1922, **44**, 1239) that in salts such as $[Ni,6NH_3]Cl_2$ the units have the customary octahedral distribution. In view of this conclusion, and especially because there was no recorded attempt at the resolution of the complex salt $[Ni(en)_3]Cl_2$, the present research was undertaken, but with negative results.

For the resolution of triethylenediaminecobaltic chloride, Werner (*loc. cit.*) used the chloride- or bromide-tartrate, $[Co(en)_3]^{X}_{C_4H_4O_6}$, since he had found the normal tartrate unsuitable; and we therefore attempted to prepare the chloride-tartrate from $[Ni(en)_3]Cl_2$ by a similar method, *viz.*, the use of one equivalent of silver tartrate. It was found, however, that on crystallisation the solution gave rise to a mixture of the normal tartrate and the original chloride. Consequently, it was decided to attempt the fractional crystallisation of the normal *tartrate*, a solution of which was obtained by triturating a solution of the chloride with the theoretical amount of silver tartrate and repeatedly extracting the residue with hot water. On evaporation, the liquid became syrupy and the crystals which separated were difficult to filter. After several recrystallisations, no difference in rotatory power could be detected, although there seemed to be two tartrates present, one crystalline and the other a gel—the deep violet colour of the solution rendered accurate reading of small rotations difficult.

Although warm hydrobromic acid converts the tartrates of triethylenediaminecobalt into the bromides (Werner, *loc. cit.*), yet in the case of the nickel salt this acid effects a complete disruption of the complex ion, even in the cold, with the formation of nickel bromide and ethylenediamine hydrobromide; hence it appears that the nickel complex ion is less stable than its cobalt analogue. This disruption of the nickel salt was avoided by the addition of barium chloride solution in excess to a solution of the complex tartrate; the filtrate was then treated with alcohol to complete the precipitation of barium tartrate and examined in the polarimeter, but all fractions of the complex tartrate treated in this way were found to yield inactive solutions.

Since it was possible that tartaric acid was too weak an acid to

effect a good resolution (see Pope, J., 1899, **75**, 1105), the stronger acid, *d*-camphorsulphonic acid, was used. On crystallisation, the *triethylenediaminenickel* d-*camphorsulphonate* showed no tendency to form a gel, but after several recrystallisations, the difference in rotatory power between the first and last fractions was still too small to warrant the assumption that a resolution had been effected.

Thus it seems either that the rotatory power of the active nickel triethylenediamine is very small or that racemisation in solution is extremely rapid.

EXPERIMENTAL.

Preparation of Triethylenediaminenickel Chloride.—The method used was that of Werner and others (*Z. anorg. Chem.*, 1899, **21**, 201). Ethylenediamine hydrate (3 mols.) was added to a concentrated solution of pure crystallised nickel chloride (1 mol.), the solution evaporated and crystallised, and the crystals twice recrystallised from water (Found: Ni, 16·85. Calc. for $[Ni(en)_3]Cl_2,2H_2O$: Ni, 16·95%).

Attempted Preparation of the Chloride–Tartrate.—A concentrated solution of the complex chloride (5 g.) was triturated with silver tartrate (2·5 g.), prepared from a concentrated solution of Rochelle salt by precipitation with concentrated silver nitrate solution, washing with water, and drying in a desiccator covered with black paper. The residue of silver chloride was repeatedly extracted with hot water and the extracts were filtered and evaporated. Different fractions of the deep violet crystals had nickel contents varying from 14·1 to 16·5%. Thus it is probable that the chloride–tartrate cannot be isolated and that the crystals obtained were mixtures of the tartrate and the chloride (Calc. for $[Ni(en)_3](C_4H_4O_6),2H_2O$: Ni, 13·8; for $[Ni(en)_3]_2\overset{Cl_2}{(C_4H_4O_6)}$: Ni, 16·8%).

Preparation of Triethylenediaminenickel Tartrate.—A concentrated solution of triethylenediaminenickel chloride (4 g.) was triturated with silver tartrate (4 g.), and worked up as in the preceding case. The filtrate was very gel-like, rendering filtration difficult. Various fractions of crystals were dried on a porous plate, and all gave a constant nickel content (Found: Ni, 13·2; N, 19·3.

$$[Ni(en)_3](C_4H_4O_6),3H_2O$$

requires Ni, 13·3; N, 19·1%). Rotations of this substance were measured in a 0·5-dm. tube; after four recrystallisations the values of $[\alpha]_D$ for the first and last fractions were 17° and 21° respectively (α_D 0·11° and 0·15°). This difference is not greater than the probable experimental error. The tartrate was converted into the corresponding chloride by the method described above, but in each case the resulting solution was inactive.

Preparation of Triethylenediaminenickel d-*Camphorsulphonate.*—To 200 c.c. of a solution of silver nitrate (15 g.), just sufficient sodium hydroxide was added to precipitate all the silver as oxide; this was washed with distilled water until free from alkali salts, filtered, and the moist precipitate (11 g.) warmed with 150 c.c. of a solution of *d*-camphorsulphonic acid (20·5 g.). When dissolution of the oxide was complete, the filtered solution was neutral to litmus and contained 10 g. of the silver salt in 40 c.c. To 20 c.c. of a solution of recrystallised triethylenediaminenickel chloride (5 g.), 40 c.c. of the silver *d*-camphorsulphonate solution were added in small portions until the addition of one drop caused no more silver chloride to be precipitated; the solution was filtered, evaporated, and crystallised (Found: Ni, 8·15.

$$[Ni(en)_3](C_{10}H_{15}O_4S)_2,H_2O$$

requires Ni, 8·16%). The substance contained no chlorine. It was recrystallised several times from water, and rotations were measured for the mercury yellow line in a 0·5-dm. tube. No difference in rotation could be detected even after four recrystallisations, and $[\alpha]$ was constant at 17°.

The authors wish to express their grateful thanks to the Department of Scientific and Industrial Research for the award of a research grant to one of them (W. R. B.), and to the Chemical Society for a grant in aid of this investigation.

UNIVERSITY OF BIRMINGHAM,
EDGBASTON. [*Received, June 27th,* 1928.]

CCCLXIII.—*Complex Oxalates of Quinquevalent Molybdenum.*

By HENRY MILLS SPITTLE and WILLIAM WARDLAW.

SOME years ago Bailhache (*Bull. Soc. chim.*, 1903, **29**, 161; 1905, **33**, 439) prepared and investigated three crystalline complex oxalates of quinquevalent molybdenum, to which he assigned the formulæ $Mo_2O_2(OH)_6(C_2O_4)_2H_2Ba,H_2O$ and

$$Mo_2O_3(OH)_4(C_2O_3)_2(OH)_2R_2,2H_2O,$$

where R = K or NH_4. Such a formulation gives no indication of the relationship, structure, or reactions of these compounds, which therefore seemed to afford an opportunity for testing the value of Werner's co-ordination theory in elucidating the structure of chemical compounds, for by applying the principles of that theory, it was possible to consider these substances as members of a series

of the general formula $R[MoO_2(C_2O_4),xH_2O]$ where R=K, (NH_4), $\frac{1}{2}$Ba, etc.

In order to determine whether such a hypothesis was justifiable, and to investigate further the chemistry of molybdenum, we have prepared new members of the series, including the complex *acid* and *pyridinium* and *quinolinium* salts, and have submitted all these compounds to a physico-chemical examination.

EXPERIMENTAL.

In a previous communication (J., 1927, 2145) the preparation of salts of the type $R_2[MoOCl_5]$ was described. It has been found that when concentrated solutions of the pyridinium and quinolinium derivatives of this series are treated with oxalic acid, red solutions are obtained from which yellow solids separate. These substances have been shown to be complex oxalates. When the potassium and ammonium complex chlorides are similarly treated, red solutions are obtained, but owing to their high solubility, the resulting products are not precipitated.

Quinolinium Molybdenum Dioxyoxalate.—This new salt was prepared by adding 30 c.c. of a warm aqueous solution of oxalic acid (1·2 g.) to 30 c.c. of a solution containing 5·6 g. of $(C_9H_8N)_2[MoOCl_5],H_2O$, boiling the solution, filtering it hot, and cooling it; a bright yellowish-brown powder was thus obtained, which, after being washed with cold water and recrystallised from hot water, was dried in a vacuum over calcium chloride.

Analysis. The molybdenum was estimated by ignition of the compound to the trioxide, or by precipitation as trisulphide (J., 1924, **125**, 1911) and oxidation to trioxide, which was weighed. The nitrogen was determined by the method of Dumas, and the oxalate by the following process: To 200 c.c. of a boiling aqueous solution of the complex salt (0·3 g.), 5 c.c. of potassium hydroxide solution (20%) were added. The precipitated hydroxide was removed, and the colourless filtrate concentrated to about 30 c.c. One c.c. of nitric acid (5*N*) was now added, and after boiling for about 2 minutes, the solution was acidified with sulphuric acid and titrated with standard potassium permanganate {Found: Mo, 26·3; C_2O_4, 24·3; N, 3·9. $(C_9H_8N)[MoO_2(C_2O_4),H_2O]$ requires Mo, 26·4; C_2O_4, 24·2; N, 3·85%}.

The formation of this salt is in accordance with the scheme of hydrolysis and ionisation previously proposed (*loc. cit.*) for the complex chlorides $R_2[MoOCl_5]$.

Complex Pyridinium Molybdenum Oxyoxalates.—50 C.c. of a warm aqueous solution of oxalic acid (4·8 g.) were added to 50 c.c. of a solution of $(C_5H_6N)_2[MoOCl_5]$ (18·4 g.) and the mixture was heated.

There separated on cooling an orange-yellow powder, which was washed with cold water and dried in a vacuum over calcium chloride {Found: Mo, 31·6; C_2O_4, 29·0; N, 3·5; C, 22·6*; H, 2·5*; $Mo:C_2O_4:N:C:H=4:4:3:23:30$. $(C_5H_6N)_3H[Mo_4O_8(C_2O_4)_4,6H_2O]$. or $(C_5H_6N)_3[Mo_4O_7(OH)(C_2O_4)_4,6H_2O]$ requires Mo, 31·6; C_2O_4, 29·0; N, 3·5; C, 22·7; H, 2·6%; $Mo:C_2O_4:N:C:H = 4:4:3:23:31$}. The presence of quinquevalent molybdenum in this compound was confirmed by a valency determination.

In an attempt to prepare a normal salt from the above pyridinium salt, 1—2 g. of this compound were gently boiled under reflux with about 20 c.c. of pyridine. After removal of the pyridine by decantation, the operation was repeated on the product, and after drying in a vacuum over concentrated sulphuric acid until free from pyridine, the final product was a pale yellow powder, soluble in water {Found: Mo, 25·4; C_2O_4, 23·3; N, 7·4. $(C_5H_6N)[MoO_2(C_2O_4),C_5H_5N]$ requires Mo, 25·6; C_2O_4, 23·5; N, 7·5%}. Valency determinations indicated that quinquevalent molybdenum was present.

Treatment of the quinolinium complex oxalate with quinoline did not result in the replacement of the water molecule owing to the oxidation of the molybdenum.

Barium Molybdenum Dioxyoxalate.—For the preparation of this compound (barium oxalomolybdite), Bailhache (*loc. cit.*) used two methods. The second method, which he considered preferable, involved the reduction of a hydrochloric acid solution of ammonium molybdate by red phosphorus, and addition of ammonium oxalate and barium chloride to the solution of quinquevalent molybdenum obtained. It was found, however, that this method yielded an impure salt containing a small amount of phosphate, and it was discarded in favour of the following method: 300 C.c. of an aqueous solution of oxalic acid (12 g.) were added to 300 c.c. of a solution of $(NH_4)_2[MoOCl_5]$ (35 g.) and the mixture was warmed. To the blood-red solution produced, barium chloride (11 g.) in 600 c.c. of water was added, and on heating to about 70°, a red, crystalline solid separated, which was collected hot, washed with hot water, and dried over calcium chloride in a vacuum {Found: Mo, 29·0; Ba, 20·8; C_2O_4, 26·6. Calc. for $Ba[MoO_2(C_2O_4)]_2,5H_2O$: Mo, 29·1; Ba, 20·8; C_2O_4, 26·7%}. An equally satisfactory product was obtained by use of the pyridinium and quinolinium derivatives of the series $R_2[MoOCl_5]$.

The very soluble ammonium and potassium and the less soluble pyridinium and quinolinium compounds can readily be prepared by double decomposition of this insoluble barium salt with the appropriate sulphate.

* Microanalysis.

Potassium Molybdenum Dioxyoxalate.—A satisfactory yield of this substance was obtained by the following method used by Bailhache, who, however, gave no experimental details. To 30 c.c. of a boiling aqueous solution of potassium sulphate (1·7 g.), barium molybdenum dioxyoxalate (7·0 g.) was added, and, after the mixture had been boiled for some minutes in a current of nitrogen, the insoluble sulphate was removed by filtration. If the filtrate was concentrated over phosphoric oxide at room temperature, tufts of golden needles were obtained, sometimes associated with red crystals. The yellow were separated from the red crystals by hand-picking and dried on a porous plate (Found: Mo, 30·3; C_2O_4, 27·8; K, 12·2. $K[MoO_2(C_2O_4),3{\cdot}5H_2O]$ requires Mo, 30·2; C_2O_4, 27·7; K, 12·3%).

The red crystals (Found: Mo, 32·0; C_2O_4, 29·3. Calc. for $K[MoO_2(C_2O_4),2{\cdot}5H_2O]$: Mo, 32·0; C_2O_4, 29·3%) proved to be the less hydrated compound analysed by Bailhache. This red form separates in a pure condition from a very concentrated solution of the potassium complex oxalate (prepared as described) which has been slowly cooled and inoculated with a red crystal.

By drying over sulphuric acid in a vacuum, either form loses water and produces a yellow powder of the empirical formula $K[MoO_2(C_2O_4),1{\cdot}5H_2O]$ (Found: Mo, 34·0; C_2O_4, 31·4. Calc.: Mo, 34·0; C_2O_4, 31·2%).

On concentration of a solution of any of these hydrated salts at 100° in a vacuum, a red solid results (Found: Mo, 35·4; Mo : C_2O_4 = 1·00 : 1·00. $K[MoO_2(C_2O_4),H_2O]$ requires Mo, 35·2%); this was formulated by Bailhache (*loc. cit.*) as $Mo_2O_5(C_2O_3)_2(OH)_2K_2$, which may be rewritten as $K[MoO_2(C_2O_4),0{\cdot}5H_2O]$. In no case, however, have the present authors been able to obtain a substance with a lower water content than that demanded by

$$K[MoO_2(C_2O_4),H_2O].$$

Ammonium Molybdenum Dioxyoxalate.—This salt was prepared by double decomposition of ammonium sulphate (1·3 g.) and barium molybdenum dioxyoxalate (7·5 g.). The preparation should be carried out in an atmosphere of nitrogen, for an aqueous solution of this salt oxidises more readily than a solution of the potassium derivative. The salt in the form of tufts of golden needles could not be isolated in sufficient quantity for analysis. By methods similar to those described for the isolation of the red crystals of the potassium salt, there were obtained orange crystals of the empirical formula $(NH_4)[MoO_2(C_2O_4),2{\cdot}5H_2O]$ (Found: Mo, 34·4; C_2O_4, 31·6; NH_4, 6·5. Calc.: Mo, 34·4; C_2O_4, 31·5; NH_4, 6·5%). On drying this salt over sulphuric acid in a vacuum, a yellow powder was obtained (Found: Mo, 36·6; C_2O_4, 33·6; NH_4, 6·9. Calc. for

$(NH_4)[MoO_2(C_2O_4),1{\cdot}5H_2O]$: Mo, 36·8; C_2O_4, 33·7; NH_4, 6·9%). When a solution of this ammonium salt was evaporated to dryness in a vacuum at 100°, a brittle red crust was obtained similar in composition to the potassium analogue {Found: Mo, 38·0; $Mo : C_2O_4 : NH_4 = 1{\cdot}00 : 1{\cdot}00 : 1{\cdot}01$. $(NH_4)[MoO_2(C_2O_4),H_2O]$ requires Mo, 38·1%}.

Quinolinium Molybdenum Dioxyoxalate.—Barium molybdenum dioxyoxalate (7·0 g.) was added to quinolinium sulphate (3·5 g.) dissolved in 60 c.c. of boiling water. After being boiled for some minutes in an atmosphere of nitrogen, the liquid was filtered hot, and the bright yellowish-brown crystals which separated were washed with cold water and dried in a vacuum over calcium chloride {Found: Mo, 26·2; C_2O_4, 24·2; N, 3·85; C, 35·7*; H, 2·65*. Calc. for $(C_9H_8N)[MoO_2(C_2O_4),H_2O]$: Mo, 26·4; C_2O_4, 24·2; N, 3·85; C, 36·3; H, 2·8%}.

Complex Pyridinium Molybdenum Oxyoxalates.—By analogy with the potassium, ammonium, and quinolinium salts, a pyridinium salt of the type $(C_5H_6N)[MoO_2(C_2O_4),xH_2O]$ should be formed by interaction of pyridinium sulphate with barium molybdenum dioxyoxalate. In the preparation of a pyridinium salt from the pyridinium complex chloride $(C_5H_6N)_2[MoOCl_5]$, however, a normal salt was not obtained (p. 2744). The following method yields a normal salt provided that the details are carefully observed. To 15 c.c. of boiling water, pyridinium sulphate (1·2 g.) and then barium molybdenum dioxyoxalate (3·5 g.) were quickly added. After boiling for 1 minute, the liquid was immediately filtered hot. The deep chrome-yellow powder, which separated from the filtrate on rapid cooling, was dried in a vacuum over calcium chloride {Found: Mo, 30·6; C_2O_4, 28·1; N, 4·4. $(C_5H_6N)[MoO_2(C_2O_4),H_2O]$ requires Mo, 30·6; C_2O_4, 28·0; N, 4·5%}.

This normal salt is rapidly decomposed on boiling with water, and a yellow solid of varying composition separates from the aqueous solution on cooling. If, however, the pyridine is removed from the reaction, the acid salt is formed in accordance with the equation

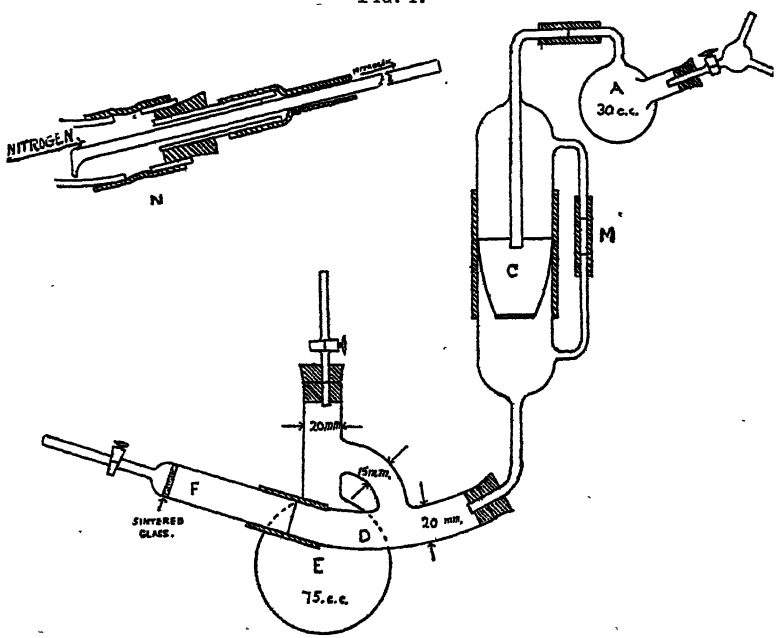
$$4(C_5H_6N)[MoO_2(C_2O_4),H_2O] + 2H_2O = (C_5H_6N)_3H[Mo_4O_8(C_2O_4)_4,6H_2O] + C_5H_5N.$$

For the preparation of this acid salt, the same reaction mixture that was used for the preparation of the normal salt was subjected to steam distillation in an atmosphere of nitrogen for about an hour to remove any liberated pyridine. The residual solution was filtered hot after concentration to about 10 c.c., and the orange-yellow powder which separated on cooling was washed with cold

* Microanalysis.

water and dried in a vacuum over calcium chloride {Found : Mo, 31·6; C_2O_4, 28·8; N, 3·5. Calc. for $(C_5H_6N)_3H[Mo_4O_8(C_2O_4)_4,6H_2O]$: Mo, 31·6; C_2O_4, 29·0; N, 3·5%}. It appears from the results of the above experiment that complex pyridinium salts with a ratio C_5H_5N : Mo of less than 3 : 4 do not exist.

In order to determine whether the molecule of water present in the normal salt could be replaced as in the case of the acid pyridinium salt, the normal salt was treated with pyridine as previously described. The product had the same empirical formula and properties as that obtained from the acid pyridinium salt {Found : Mo, 25·4; C_2O_4, 23·5; N, 7·5. Calc. for $(C_5H_6N)[MoO_2(C_2O_4)(C_5H_5N)]$: Mo, 25·6; C_2O_4, 23·5; N, 7·5%}.



An Oxyoxalate of Quinquevalent Molybdenum.—The complex oxalates so far mentioned have been considered as derivatives of a hypothetical acid, $H[MoO_2(C_2O_4),xH_2O]$. Such an acid should be formed initially when the insoluble barium salt $Ba[MoO_2(C_2O_4)]_2,5H_2O$ is treated with dilute sulphuric acid. By warming this mixture a red supernatant liquid was obtained. Titrations with standard potassium permanganate, however, showed that in the solution the molybdenum was not quinquevalent, but had been partly oxidised. It was necessary, therefore, to conduct the whole preparation in an atmosphere from which air was rigidly excluded, and the following method proved satisfactory for the isolation of a substance with the empirical formula $Mo_2O_3(C_2O_4)_2,4H_2O$.

Into *A* (Fig. 1), which consisted of a 30 c.c. flask fitted with a side tube, were introduced barium molybdenum dioxyoxalate (4·0 g.) and water (7 c.c.). The whole apparatus was evacuated, tested to prove absence of air-leaks, and filled with nitrogen; 2 c.c. of sulphuric acid (5*N*) were then added to the liquid in *A*. With a slow stream of nitrogen passing through the apparatus from *F* to *A*, the reaction mixture was gradually raised to boiling point on a water-bath; this heating should occupy about an hour, for if the mixture is boiled quickly, hydrolysed products result. After gently boiling for 5 minutes, the red liquid formed was decanted into the filtering apparatus, *C*, by rotating the flask *A* : *C* consisted of a Gooch crucible, containing a perforated plate between two filter-papers, fitted into the modified adapter. By applying suction at *F*, the liquid was drawn into *C*, and by closing *M* it was filtered into *D*, which should hold about 12 c.c. of liquid. After this filtration, the apparatus was disconnected at *D*, the open end of *D* immediately closed with a solid rubber bung, and *DEF* evacuated. The liquid was concentrated at 30—35° to about 2 c.c. by means of the phosphoric oxide contained in the flask *E* of 75 c.c. capacity. Nitrogen was admitted into *DEF*, and from the liquid, a [illegible]

orange-yellow solid slowly separated. The mixture was then transferred to the filter *F*, by means of the device *N*, a rapid stream of nitrogen being passed through the apparatus to avoid oxidation. After the liquid had been filtered in nitrogen, the vessel *F* and its contents were rapidly transferred to a nitrogen-filled desiccator and dried over sulphuric acid in a vacuum.

The pale yellow substance thus obtained [Found: Mo, 39·4; C_2O_4, 36·3. $Mo_2O_3(C_2O_4)_2,4H_2O$ requires Mo, 39·4; C_2O_4, 36·1%], which corresponds to the parent *acid*, was insoluble in cold water

FIG. 1.

or in cold concentrated hydrochloric or nitric acid, and was stable in air. In hot water it dissolved with oxidation, and in warm hydrochloric acid a green solution was produced. Red solutions resulted from treatment with dilute ammonia or alkalis. Cold water in which the solid was suspended reacted acid. Valency determinations proved that the molybdenum was quinquevalent.

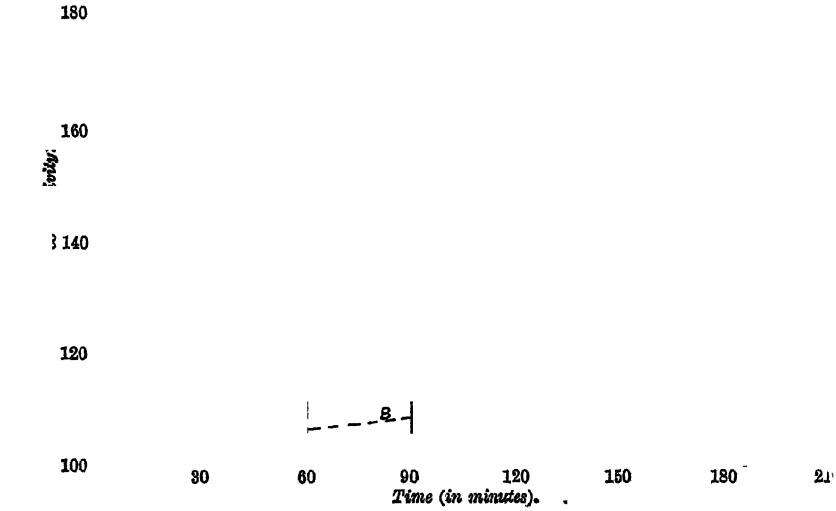
Valency of the Molybdenum.—In the presence of the oxalic acid the ordinary method (J., 1923, **123**, 969) for the determination of valency was not available, and estimations were therefore carried out by the following method. A weighed quantity of the substance, dissolved in air-free sulphuric acid (2*N*), was titrated in the cold in a nitrogen atmosphere with standard potassium permanganate. When colourless, the solution was heated to 70°, and the titration

continued until a permanent pink colour was obtained. This reading gave the amount of permanganate necessary to oxidise the molybdenum to the sexavalent state and to decompose the oxalate radical. The permanganate required for the latter purpose was estimated independently by the method already described (p. 2743). By difference the amount of permanganate required to oxidise the molybdenum to the sexavalent condition was obtained, and since 1 c.c. of *N*-permanganate = 0·096 g. Mo^{v}, the percentage of molybdenum present in the salt can be deduced. When this agrees with the results obtained by gravimetric analysis, the molybdenum is quinquevalent.

Koppel and Goldmann (*Z. anorg. Chem.*, 1903, **36**, 281) have made an interesting observation with regard to the valency titrations for the quadrivalent vanadium oxyoxalates. They found that the amount of permanganate required was less than that demanded by theory, and observed that quadrivalent vanadium oxyoxalate could not be prepared; it therefore seems probable that this compound undergoes atmospheric oxidation in a similar manner to the analogous molybdenum oxyoxalate.

General Properties.—The complex oxalates in the dry condition are stable in air, but their aqueous solutions very slowly oxidise. Concentrated aqueous solutions are blood-red, but on dilution become brownish-yellow to yellow. The substances are insoluble in such organic solvents as alcohol, ether, and benzene. Concentrated hydrochloric acid decomposes the oxalates, yielding green solutions of the complex chlorides $R_2[MoOCl_5]$, and a green solution is also obtained by the action of concentrated sulphuric acid. A red solution results from the reaction between the complex oxalates and thiocyanic acid.

Physico-chemical Measurements.



To decide whether formulæ based on Werner's co-ordination theory are applicable to these complex oxalates, determinations of their molecular weights and molecular conductivities were carried out.

Molecular-weight Determinations.—The molecular weights, as determined by the depression of the freezing point of air-free water, are shown in Table I. If the formula $K[MoO_2(C_2O_4),1{\cdot}5H_2O]$ is assigned to the potassium salt, the apparent molecular weight when ionisation is complete should be 141. The results obtained in dilute solution are in accordance with this deduction, but the apparent molecular weights in concentrated solutions, which are even greater than that demanded by the un-ionised molecule, indicate that polymerisation is taking place with the formation of such molecules as $K_2[Mo_2O_4(C_2O_4)_2,3H_2O]$. The fact that the

C. *Solution B, on addition of platinised platinum electrodes.*

oxalate ion cannot be detected by its ionic reactions shows that the increased number of ions in dilute solutions is not due to hydrolysis of the complex anion.

Molecular-conductivity Determinations.—With solutions of the various complex oxalates, it was found that the molecular conductivity in each case increased with time, and that the rate of variation was greatest with dilute solutions. This change occurred extremely slowly in the absence of the platinised platinum electrodes, but was very markedly accelerated by their presence (Fig. 2). Similar observations were made by Duff (J., 1923, **123**, 572) on the catalytic hydrolysis of the cobaltammines, and by Russ (*Z. anorg.*

Chem., 1902, **31**, 42) on the catalytic oxidation of the complex niobium oxalates by platinised platinum electrodes. On treating an aqueous solution of potassium molybdenum dioxyoxalate with platinum-black, and estimating both valency and oxalate by means of standard potassium permanganate at intervals of several days, it was found that oxidation of the molybdenum to the sexavalent state took place and was accompanied by decolorisation of the solution.

FIG. 3.

It was therefore necessary to determine the conductivity by taking time curves for the conductivity at each dilution (see J., 1927, 515), and deducing the initial conductivities from these. Table II gives the values of μ for various dilutions (v litres per mol.) at 25° at zero time, and for comparison the values of molecular conductivities at 25° of typical salts (Noyes and Falk, *J. Amer. Chem. Soc.*, 1912, **34**, 454) are given in Table III.

In dilute solutions the molecular conductivities are similar to those of a typical binary electrolyte (Fig. 3) and support the formulation $R[MoO_2(C_2O_4)_2,xH_2O]$ for the molybdenum dioxyoxalates

FIG. 4.

investigated above. The Ostwald–Walden rule does not apply in the case of these complex oxalates, for $\frac{1}{10}(\lambda_{1024} - \lambda_{32})$ has a value of approximately 2 for both salts. This may be due to the polymerisation that takes place in their concentrated solutions. Russ (*loc. cit.*) obtained similar results with the complex niobium oxalates. A further indication that these molybdenum dioxyoxalates behave abnormally is afforded by the graphs obtained by plotting $\sqrt[3]{1/v}$

against μ. Binary electrolytes in dilute solutions, unlike ternary electrolytes, give straight lines, but the complex oxalates give a curve (Fig. 4) agreeing with the idea that polymerisation to a more complex electrolyte takes place in solutions of higher concentration. Cadmium iodide, which is known to undergo extensive polymerisation in solution, is included for comparison.

Complex Pyridinium Molybdenum Oxyoxalate.—From the analytical data an empirical formula $(C_5H_6N)_3H[Mo_4O_8(C_2O_4)_4,6H_2O]$ or $(C_5H_6N)_3[Mo_4O_7(OH)(C_2O_4)_4,6H_2O]$ was assigned to this orange-yellow compound. It was impossible, however, without further data finally to decide as to the constitution of this salt, although the fact that in aqueous solution it reacts acid to litmus and bromophenol-blue favours the first formula. Determinations of molecular weight by the depression of the freezing point of water indicated that in dilute solutions considerable ionisation occurred—owing to the comparative insolubility of the compound it was possible to determine molecular weights and conductivities only over a limited range of concentrations :

G. of substance per 100 g. water.	Conc. (mols. per 1000 g. water).	Apparent mol. wt.	Osmotic factor.
0·506	0·00417	184	6·59
1·049	0·00864	195	6·22
1·684	0·01388	198	6·12

It is obvious from the results that, although primary ionisation may take place in accordance with the first formula, further decomposition of the complex anion must occur, for with such a formulation, the complex salt even at infinite dilution should yield a maximum of five ions by primary ionisation, and give an apparent molecular weight of 243, whereas the osmotic factor suggests that at least seven ions are present at the concentrations used. It may be inferred, therefore, that in all probability the complex anion undergoes decomposition, possibly in accordance with the following scheme :

$$(C_5H_6N)_3H[Mo_4O_8(C_2O_4)_4,6H_2O] \rightleftharpoons 3C_5H_6N^{\cdot} + H^{\cdot} + [Mo_4O_8(C_2O_4),6H_2O]''''$$

$$[Mo_4O_8(C_2O_4)_4,6H_2O]'''' \rightleftharpoons 4[MoO_2(C_2O_4),xH_2O]'.$$

Taylor (*Z. physikal. Chem.*, 1898, **27**, 361) obtained an osmotic factor of 5·92 for sodium mellitate, $Na_6C_{12}O_{12}$, in 0·00181*M* concentration.

If such a scheme operates, it should be possible to deduce the value of μ_∞ for this complex salt. Since μ_∞ for both $K[MoO_2(C_2O_4),1{\cdot}5H_2O]$ and $(NH_4)[MoO_2(C_2O_4),1{\cdot}5H_2O]$ is approximately 120, it follows that the ionic mobility of the complex anion

$[MoO_2(C_2O_4),xH_2O]'$ is approximately 46, the values of the ionic mobilities of the potassium and ammonium ions being 74·4 and 74·0 respectively at 25°. The possibility that there might be an error in the value of this ionic mobility due to the hydrolysis

$$R[MoO_2(C_2O_4),1{\cdot}5H_2O] + H_2O \rightleftharpoons ROH + H[MoO_2(C_2O_4),1{\cdot}5H_2O]$$

analogous to that of potassium cyanide, was disproved by the fact that the solutions of the complex oxalates, unlike those of potassium cyanide, do not give an alkaline reaction.

The above scheme indicates that μ_∞ for the complex pyridinium molybdenum oxyoxalate should be given by the sum of the ionic mobilities of $3C_5H_6N^{\cdot} + H^{\cdot} + 4[MoO_2(C_2O_4),xH_2O]'$, which is 660, whereas the following experimental data lead to a value of 570:

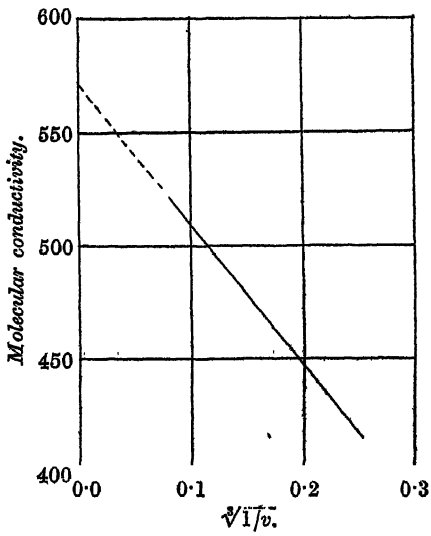
v	65·13	151·6	196·9	719·9	2043·0
μ	419·7	452·8	464·5	503·1	521·0

Although no satisfactory explanation of the discrepancy between the two values for μ_∞ is apparent, it seems that an experimental value of this magnitude can only be explained by the supposition that a hydrogen ion is formed by this salt on solution, and that the constitution of this salt can be adequately expressed by the co-ordination formula $(C_5H_6N)_3H[Mo_4O_8(C_2O_4)_4,6H_2O]$. The graph (Fig. 5) obtained with the acid pyridinium salt when $\sqrt[3]{1/v}$ is plotted against μ is a straight line, but this may be accounted for by the very small range of concentrations over which the conductivities could be determined.

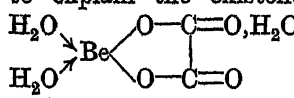
Discussion of Results.

Molybdenum oxyoxalate, $Mo_2O_3(C_2O_4)_2,4H_2O$, is an interesting example of a compound which is unstable and very reactive in solution, but far less reactive in the solid state, thus typifying the properties of polymerisable substances. Although from analytical data the above formula was assigned to this substance, yet a consideration of its markedly acidic properties and its method of preparation makes it clear that it is more adequately represented by the co-ordination formula $H[MoO_2(C_2O_4),1{\cdot}5H_2O]$. It thus becomes the parent acid of this series of complex oxalates.

With the exception of the acid pyridinium salt, the compounds of this series dealt with in this communication can be represented by the general formula $R[MoO_2(C_2O_4),xH_2O]$, where $x = 1$, 1·5, 2·5, or 3·5. Of these four groups of hydrates, the first appears to be the most general, and the suggestion that this is the normal one is strengthened by the fact that when the pyridinium salt



$$(C_5H_6N)[MoO_2(C_2O_4),H_2O]$$



is boiled with pyridine, a salt $(C_5H_6N)[MoO_2(C_2O_4),C_5H_5N]$, con-

taining only one co-ordinated pyridine molecule, is produced. On Werner's theory these compounds apparently possess a co-ordination number of five, instead of the usual six for molybdenum compounds. This anomaly affords additional evidence for the theory of polymerisation put forward in the physicochemical section, for by considering two of the co-ordinating groups as bridge groups, the polymerised salts can be represented as six-point systems.

This theory of polymerisation is also needed to explain the existence of the acid pyridinium salt; moreover, it is necessary in the case of the higher hydrates, all of which can only be represented rationally by a formula which in the simplest case would be $R_2[Mo_2O_4(C_2O_4)_2,yH_2O]$, where $y = 3$, 5, or 7.

FIG. 5.

The large number of water molecules (5 or 7) in the higher hydrates of such a series is very difficult to explain, since the normal co-ordination number of six is exceeded. Such hydrated forms are only obtained in the crystalline state, and the extra molecules of water are only loosely held. Sidgwick (J., 1926, 1301) put forward a theory of the monohydration of the oxalate group both in the ionic and oxalato-form, in order to explain the existence of $Be(C_2O_4),3H_2O$, which he suggests is  , but this theory does not fully explain the hydrates of these complex oxalates.

Barbieri (*Rend. Atti Accad. Lincei*, 1916, 775) has described the preparation of another series of oxalates of quinquevalent molybdenum of the general formula $R_4[Mo_2O_4(C_2O_4)_3,2H_2O]$, where R = K or NH_4. These have not been investigated in the present research, but it may be noted that they contain two molybdenum atoms and have a co-ordination number of six.

In his papers on the series of complex oxalates, Bailhache (*loc. cit.*) suggests for the potassium, ammonium, and barium salts the

name "oxalomolybdites," but it is felt that the use of the name "dioxyoxalates" would be more in accordance with modern nomenclature.

The authors wish to express their thanks to the Department of Scientific and Industrial Research for the award of a grant to one of them (H. M. S.), and to the Chemical Society and Messrs. Brunner Mond and Co., Ltd., for grants in aid of this investigation.

UNIVERSITY OF BIRMINGHAM,
EDGBASTON. [*Received, August 2nd,* 1928.]

CCCLXIV.—*The Interaction of Chloral and 2 : 4 : 6-Trihalogen-substituted Phenylhydrazines.*

By FREDERICK DANIEL CHATTAWAY and FRANCIS GEORGE DALDY.

IT has recently been shown (Chattaway and Bennett, J., 1927, 2850) that the violence of the reaction which occurs when chloral and phenylhydrazine are brought together is so moderated by the presence of halogen atoms in the hydrazine nucleus that the products, which differ according to the solvent in which the reaction takes place, can be isolated.

The reaction between chloral and the 2 : 4 : 6-trihalogen-substituted phenylhydrazines proceeds with such smoothness that its course can be completely followed. When chloral reacts with 2 : 4 : 6-trichlorophenylhydrazine, for example, it at first behaves normally, yielding a pale yellow hydrazone (I); this compound is extremely unstable and loses hydrogen chloride rapidly at the ordinary temperature, giving a compound (II) of a brilliant crimson colour which is indifferent to acetic anhydride and yields 2 : 4 : 6-trichloroaniline on reduction: it must therefore have an azo-structure and its composition shows it to be *αα-dichloro*-β-2 : 4 : 6-*trichlorobenzeneazoethylene*.

The elimination of hydrogen chloride from the initially formed hydrazone is a reversible reaction, for when a solution of the azo-compound (II) in hot acetic anhydride is saturated with hydrogen chloride, *chloral-α-acetyl*-2 : 4 : 6-*trichlorophenylhydrazone* is formed. The reaction may therefore be expressed:

$$NHX\cdot NH_2 + CCl_3\cdot CHO \longrightarrow \underset{(I.)}{[NHX\cdot N{:}CH\cdot CCl_3]} \rightleftarrows \underset{(II.)}{NX{:}N\cdot CH{:}CCl_2} + HCl.$$

$$[X = C_6H_2Cl_3(2:4:6)].$$

Further evidence confirming the constitution of the crimson condensation product is afforded by the action of halogens upon it.

It combines with chlorine, for example, to give a yellow addition product (III), which from its colour must be regarded as having a hydrazone structure, the hydrogen atom previously attached to the methine carbon atom now being attached to the α-nitrogen atom. This compound, like the structurally analogous hydrazone (I), loses hydrogen chloride on warming with acetic acid or acetic anhydride, the colour reverting to crimson, since the azo-structure is re-established, the methine chlorine-substituted azo-compound, *ααβ-trichloro-β-2 : 4 : 6-trichlorobenzeneazoethylene* (IV), being formed.

$$\text{(III.)}\quad NHX\cdot N{:}CCl\cdot CCl_3 \longrightarrow NX{:}N\cdot CCl{:}CCl_2 + HCl \quad \text{(IV.)}$$

When the crimson compound (II) is heated with acetic acid containing hydrogen chloride, it is converted into *glyoxylic acid* 2 : 4 : 6-*trichlorophenylhydrazone*, and if it is heated with alcoholic hydrogen chloride, *ethyl glyoxylate* 2 : 4 : 6-*trichlorophenylhydrazone* is formed, the action in each case depending on the reversible nature of the elimination of hydrogen chloride from the 2 : 4 : 6-trichlorophenylhydrazone of chloral. This behaviour explains the formation of an alkyl glyoxylate 2 : 4 : 6-trichlorophenylhydrazone when chloral reacts with 2 : 4 : 6-trichlorophenylhydrazine in the corresponding alcohol.

The formation of the 2 : 4 : 6-trichlorophenylhydrazones of glyoxylic acid or the alkyl glyoxylates is due to the hydrolysis of the CCl_3 group of the chloralphenylhydrazone, but this is a much slower reaction than the elimination of hydrogen chloride; consequently, when the reaction between chloral and 2 : 4 : 6-trichlorophenylhydrazine takes place in acetic acid or alcoholic solution, there first occurs an almost complete formation of the azo-ethylene, which, as the hydrolysis proceeds, again combines with the hydrogen chloride.

When the reaction takes place in alcoholic solution, the reaction mixture turns brilliant crimson and the azo-ethylene can be isolated from it, but the colour gradually disappears as recombination with hydrogen chloride takes place and hydrolysis proceeds.

The formation of the glyoxylic acid and alkyl glyoxylate phenylhydrazones is therefore much facilitated by the presence of excess of hydrogen chloride during the reaction, which may be represented

$$NX{:}N\cdot CH{:}CCl_2 + HCl \rightleftharpoons NHX\cdot N{:}CH\cdot CCl_3 \xrightarrow{ROH} NHX\cdot N{:}CH\cdot CO_2R.$$

The action of halogens upon the 2 : 4 : 6-trichlorophenylhydrazones of glyoxylic acid or its esters yields the corresponding ω-halogen- hydrazones, which are also formed when the azo-compounds

are heated in presence of hydrogen chloride with acetic acid or alcohol, respectively.

$$NHX{\cdot}N{:}CH{\cdot}CO_2R \xrightarrow{Cl_2} NHX{\cdot}N{:}CCl{\cdot}CO_2R \xleftarrow[HCl]{ROH} NX{:}N{\cdot}CCl{:}CCl_2.$$

ω-Halogenated alkyl glyoxylate 2 : 4 : 6-trichlorophenylhydrazones can also be obtained by esterification of the corresponding ω-halogenated glyoxylic acid 2 : 4 : 6-trichlorophenylhydrazones, and very readily by the action of chlorine or bromine on *ethyl* 2 : 4 : 6-*trichlorobenzeneazoacetoacetate*, prepared by coupling 2 : 4 : 6-trichlorobenzenediazonium chloride with ethyl acetoacetate (compare Bülow and Neber, *Ber.*, 1912, **45**, 3732); the acetyl group is removed and replaced by halogen; *e.g.*,

$$CH_3{\cdot}C(OH){:}\underset{CO_2Et}{CH} \xrightarrow{X{\cdot}N_2Cl} NHX{\cdot}N{:}\underset{CO_2Et}{C}{\cdot}CO{\cdot}CH_3 \xrightarrow{Cl_2} NHX{\cdot}N{:}\underset{CO_2Et}{CCl}$$

The stability of the ω-halogenated 2 : 4 : 6-trichlorophenylhydrazones of glyoxylic acid and its esters is remarkable: for instance, the halogen atom is not affected by boiling for a short time with alcoholic ammonia, a process which readily yields a hydrazidine in the case of the ω-halogenated benzaldehyde- and *m*-nitrobenzaldehyde-2 : 4 : 6-trichlorophenylhydrazones.

EXPERIMENTAL.

When condensation of chloral and an arylhydrazine takes place in aqueous solution, the azo-ethylene, being practically insoluble in this solvent, separates and comparatively little hydrolysis occurs; but with acetic acid or alcohol as solvent, the azo-ethylene is first formed, giving the reaction mixture an intense crimson colour, and unless the hydrogen chloride is removed, hydrolysis occurs, the crimson colour disappears, and the hydrazone of glyoxylic acid or its ester is formed. If, however, the acetic acid contains excess of sodium acetate, recombination with hydrogen chloride and hydrolysis are prevented, and the azo-ethylene can be isolated.

Action of 2 : 4 : 6-*Trichlorophenylhydrazine Hydrochloride on Chloral Hydrate.*—(1) *In aqueous solution.* Chloral hydrate (9 g.; 1 mol.) and 2 : 4 : 6-trichlorophenylhydrazine hydrochloride (13·5 g.; 1 mol.) were dissolved in 1000 c.c. of hot water containing 20 c.c. of hydrochloric acid, and the mixture was heated nearly to boiling. As the temperature approached 80°, the liquid became turbid and *αα-dichloro*-β-2 : 4 : 6-*trichlorobenzeneazoethylene* separated in minute drops which coalesced to a viscid liquid of a brilliant crimson colour and solidified on cooling to a hard crimson cake. It crystallised from alcohol, in which it was very easily soluble, in deep crimson,

acicular plates, m. p. 54° (Found : Cl, 58·05. $C_8H_3N_2Cl_5$ requires Cl, 58·25%).

(2) *In acetic acid solution in presence of sodium acetate.* The same quantities of reactants in 40 c.c. of acetic acid were warmed to 60°, the liquid turning deep crimson and hydrogen chloride being evolved; 8 g. (2 mols.) of finely powdered, anhydrous sodium acetate were then added, the mixture was heated on a water-bath for ½ hour, and the αα-dichloro-β-2 : 4 : 6-trichlorobenzeneazoethylene, which separated as a dark red liquid and solidified on cooling, was crystallised from alcohol.

(3) *In acetic acid solution.* If in the foregoing experiment, the mixture was heated to boiling without the addition of sodium acetate, after 10 minutes the colour had faded to orange, and on cooling, glyoxylic acid 2 : 4 : 6-trichlorophenylhydrazone separated. It crystallised from acetic acid, in which it was extremely soluble, in pale yellow, elongated plates, m. p. 167° (decomp.), identical with specimens prepared by direct synthesis.

(4) *In ethyl-alcoholic solution.* The hydrazine hydrochloride (12 g.; 1 mol.) was suspended in 50 c.c. of ethyl alcohol and 8 g. (1 mol.) of chloral hydrate were added; on being warmed for a few minutes, the solution turned crimson owing to the formation of the αα-dichloro-β-2 : 4 : 6-trichlorobenzeneazoethylene, for when a portion of the clear liquid was cooled, that compound separated. On further heating, the crimson colour slowly faded, and after an hour's boiling a clear yellow solution was obtained from which *ethyl glyoxylate* 2 : 4 : 6-*trichlorophenylhydrazone* separated on cooling. When crystallised from boiling alcohol, in which it was very soluble, it separated in pale yellow prisms, the colour deepening on exposure to daylight; m. p. 97·5° (Found : Cl, 36·1. $C_{10}H_9O_2N_2Cl_3$ requires Cl, 36·0%).

Reactions of αα-Dichloro-β-2 : 4 : 6-trichlorobenzeneazoethylene.—(1) *With alcohol.* 5 G. of the foregoing benzeneazoethylene were boiled with 25 c.c. of alcohol : after 8 hours, the crimson colour had changed to pale yellow, and on cooling, ethyl glyoxylate 2 : 4 : 6-trichlorophenylhydrazone separated. In a similar experiment in which the alcohol was first saturated with hydrogen chloride, the reaction was complete after 1 hour's boiling.

(2) *Formation of chloral-α-acetyl-2 : 4 : 6-trichlorophenylhydrazone.* A solution of 5 g. of αα-dichloro-β-2 : 4 : 6-trichlorobenzeneazoethylene in 10 c.c. of acetic anhydride was saturated at 80° with dry hydrogen chloride; the crimson colour faded rapidly, and on cooling, *chloral-α-acetyl-2 : 4 : 6-trichlorophenylhydrazone* separated as a colourless solid. It crystallised from boiling alcohol, in which it was readily soluble, in colourless rhombs, m. p. 144° (Found : N, 7·4; Cl, 55·25. $C_{10}H_8ON_2Cl_6$ requires N, 7·3; Cl, 55·5%).

(3) *Action of chlorine.* A stream of chlorine was passed into a well-cooled suspension of 10 g. of αα-dichloro-β-2 : 4 : 6-trichlorobenzeneazoethylene in 10 c.c. of acetic acid; the temperature rose slightly, and the solid dissolved, giving a pale orange solution from which *chloral-ω-chloro-2 : 4 : 6-trichlorophenylhydrazone* separated as a red, oily liquid; this solidified on standing with the mother-liquor, and crystallised from boiling acetone, in which it was easily soluble, in small yellow prisms, m. p. 104° (Found: N, 7·2; Cl, 66·0. $C_8H_3N_2Cl_7$ requires N, 7·5; Cl, 66·2%).

If the pale orange solution was heated to boiling, hydrogen chloride was evolved and the crimson colour restored; on cooling, *ααβ-trichloro-β-2 : 4 : 6-trichlorobenzeneazoethylene* was deposited. It crystallised from alcohol, in which it was readily soluble, in long, bright red needles, m. p. 75° (Found: Cl, 63·0. $C_8H_2N_2Cl_6$ requires Cl, 62·8%).

(4) *Action of bromine.* 2 C.c. (1 mol. + excess) of bromine dissolved in 5 c.c. of acetic acid were added to 5 g. (1 mol.) of αα-dichloro-β-2 : 4 : 6-trichlorobenzeneazoethylene suspended in 15 c.c. of acetic acid; the mixture was heated at 60° for 20 minutes and then cooled; the *αα-dichloro-α-bromo-β-2 : 4 : 6-trichlorobenzeneazoethylene* which separated crystallised from alcohol, in which it was easily soluble, in brick-red needles, m. p. 108·5° (Found: Cl, 46·1; Br, 20·7. $C_8H_2N_2Cl_5Br$ requires Cl, 46·2; Br, 20·75%).

Synthesis of Glyoxylic Acid and Ethyl Glyoxylate 2 : 4 : 6-Trichlorophenylhydrazones.—60 C.c. of 0·8*N*-glyoxylic acid solution (prepared by electro-reduction of oxalic acid) were added to 12 g. of 2 : 4 : 6-trichlorophenylhydrazine hydrochloride dissolved in 1000 c.c. of boiling water; *glyoxylic acid 2 : 4 : 6-trichlorophenylhydrazone* separated as a pale yellow, flocculent precipitate. It crystallised from hot acetic acid in pale yellow, elongated plates, m. p. 167° (decomp.) (Found: Cl, 39·7. $C_8H_5O_2N_2Cl_3$ requires Cl, 39·8%). When 5 g. of this compound were boiled for 6 hours with 25 c.c. of alcohol containing 2% of hydrogen chloride, and cooled, ethyl glyoxylate 2 : 4 : 6-trichlorophenylhydrazone separated as yellow prisms, m. p. 97·5°.

Ethyl Glyoxylate α-Acetyl-2 : 4 : 6-trichlorophenylhydrazone.—5 G. of ethyl glyoxylate 2 : 4 : 6-trichlorophenylhydrazone were dissolved in 10 c.c. of hot acetic anhydride and a drop of sulphuric acid was added; a violent reaction then set in. When the mixture was cooled, *ethyl glyoxylate α-acetyl-2 : 4 : 6-trichlorophenylhydrazone* separated. It crystallised from boiling alcohol, in which it was readily soluble, in colourless rhombs, m. p. 112·5° (Found: Cl, 31·6. $C_{12}H_{11}O_3N_2Cl_3$ requires Cl, 31·5%).

Action of Chlorine on Ethyl Glyoxylate 2 : 4 : 6-Trichlorophenyl-

hydrazone.—A stream of chlorine was passed into a suspension of 7 g. of ethyl glyoxylate 2 : 4 : 6-trichlorophenylhydrazone in 20 c.c. of acetic acid; the solid gradually dissolved and when a clear solution was obtained the whole was poured into water. *Ethyl glyoxylate ω-chloro-2 : 4 : 6-trichlorophenylhydrazone* immediately separated as a bulky, white solid; it crystallised from alcohol, in which it was easily soluble, in colourless plates, m. p. 73·5°, which turned pink on exposure to light (Found : Cl, 42·8. $C_{10}H_8O_2N_2Cl_4$ requires Cl, 43·0%).

This compound was also prepared by boiling a solution of 5 g. of ααβ-trichloro-β-2 : 4 : 6-trichlorobenzeneazoethylene in 25 c.c. of alcohol for 8 hours; the crimson colour slowly faded to pale yellow, and on cooling, the required compound separated. In a similar experiment, the alcohol was first saturated with hydrogen chloride and the reaction was then completed in an hour.

Action of Bromine on Ethyl Glyoxylate 2 : 4 : 6-Trichlorophenylhydrazone.—2 C.c. (1 mol. + excess) of bromine were added to 5 g. (1 mol.) of the hydrazone dissolved in 25 c.c. of acetic acid, and the mixture was heated at 60° for ½ hour; on cooling, *ethyl glyoxylate ω-bromo-2 : 4 : 6-trichlorophenylhydrazone* separated. It crystallised from alcohol, in which it was extremely soluble, separating in feathery, white plates, m. p. 75° (Found : Cl, 28·6; Br, 21·5. $C_{10}H_8O_2N_2Cl_3Br$ requires Cl, 28·4; Br, 21·3%).

Action of Chlorine on Glyoxylic Acid 2 : 4 : 6-Trichlorophenylhydrazone.—A stream of chlorine was passed into a suspension of 10 g. of glyoxylic acid 2 : 4 : 6-trichlorophenylhydrazone in 30 c.c. of acetic acid; the temperature rose and the solid all dissolved, and on cooling, *glyoxylic acid ω-chloro-2 : 4 : 6-trichlorophenylhydrazone* separated. It crystallised from hot acetic acid in small yellow prisms, m. p. 151·5° (decomp.) (Found : Cl, 47·1. $C_8H_4O_2N_2Cl_4$ requires Cl, 47·0%).

5 G. of the foregoing compound were esterified by boiling for 6 hours with 25 c.c. of alcohol containing 2% of hydrogen chloride; when the resulting yellow solution was cooled, ethyl glyoxylate ω-chloro-2 : 4 : 6-trichlorophenylhydrazone separated as white plates, m. p. 73·5°, identical with the compound described above.

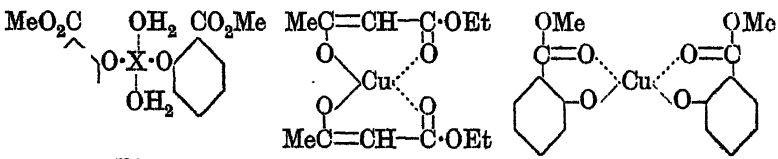
Ethyl 2 : 4 : 6-Trichlorobenzeneazoacetoacetate.—20 G. (1 mol.) of 2 : 4 : 6-trichloroaniline were diazotised and the filtered solution was added slowly and with vigorous stirring to a well-cooled mixture of 13 g. (1 mol.) of ethyl acetoacetate dissolved in 200 c.c. of alcohol and 300 g. of sodium acetate in 1500 c.c. of water. The *ethyl 2 : 4 : 6-trichlorobenzeneazoacetoacetate* that separated crystallised from alcohol in small yellow prisms, m. p. 94·5° (Found : Cl, 31·4. $C_{12}H_{11}O_3N_2Cl_3$ requires Cl, 31·5%).

Action of Chlorine and of Bromine on Ethyl 2 : 4 : 6-*Trichlorobenzeneazoacetoacetate.*—When chlorine was passed into a suspension of 5 g. of the ester in 20 c.c. of acetic acid, heat was evolved; the pale yellow solution obtained, on cooling, deposited ethyl glyoxylate ω-chloro-2 : 4 : 6-trichlorophenylhydrazone as colourless plates, m. p. 73·5°, identical with specimens previously prepared.

2 C.c. of bromine (1 mol. + excess) in 5 c.c. of acetic acid were added to 5 g. (1 mol.) of ethyl 2 : 4 : 6-trichlorobenzeneazoacetoacetate in 20 c.c. of acetic acid and the mixture was heated at 60° for ½ hour: on cooling, ethyl glyoxylate ω-bromo-2 : 4 : 6-trichlorophenylhydrazone separated in colourless needles, m. p. 75°, identical with the compound described above.

A similar series of reactions has been carried out with 2 : 4 : 6-tribromophenylhydrazine, and the following compounds prepared:— *αα-Dichloro-β-2 : 4 : 6-tribromobenzeneazoethylene*, crimson plates from alcohol, m. p. 92° (Found: C, 22·2; H, 0·9; N, 6·6; Cl, 16·2; Br, 54·7. $C_8H_3N_2Cl_2Br_3$ requires C, 21·9; H, 0·7; N, 6·4; Cl, 16·2; Br, 54·8%). *ααβ-Trichloro-β-2 : 4 : 6-tribromobenzeneazoethylene*, long, deep red, flat prisms from alcohol, m. p. 105° (Found: Cl, 22·4; Br, 50·6. $C_8H_2N_2Cl_3Br_3$ requires Cl, 22·5; Br, 50·8%). *αα-Dichloro-β-bromo-β-2 : 4 : 6-tribromobenzeneazoethylene*, flat, deep red prisms from alcohol, m. p. 115° (Found: Cl, 13·7; Br, 61·6. $C_8H_2N_2Cl_2Br_4$ requires Cl, 13·7; Br, 61·9%). *Glyoxylic acid* 2 : 4 : 6-*tribromophenylhydrazone*, faintly yellow, irregular plates from acetic acid, m. p. 170·5° (decomp.) (Found: Br, 59·6. $C_8H_5O_2N_2Br_3$ requires Br, 59·8%). *Ethyl glyoxylate* 2 : 4 : 6-*tribromophenylhydrazone*, pale yellow, flat prisms from alcohol, m. p. 126° (Found: C, 28·2; H, 2·1; N, 6·5; Br, 55·9. $C_{10}H_9O_2N_2Br_3$ requires C, 28·0; H, 2·1; N, 6·5; Br, 55·9%). *Ethyl glyoxylate α-acetyl-*2 : 4 : 6-*tribromophenylhydrazone*, colourless rhombs from alcohol, m. p. 133·5° (Found: C, 31·0; H, 2·4; N, 6·3; Br, 50·8. $C_{12}H_{11}O_3N_2Br_3$ requires C, 30·6; H, 2·4; N, 6·0; Br, 50·9%). *Ethyl glyoxylate ω-chloro-*2 : 4 : 6-*tribromophenylhydrazone*, colourless plates from alcohol, m. p. 108·5° (Found: Cl, 7·7; Br, 51·8. $C_{10}H_8O_2N_2ClBr_3$ requires Cl, 7·7; Br, 51·8%). *Ethyl glyoxylate ω-bromo-*2 : 4 : 6-*tribromophenylhydrazone*, elongated colourless plates from acetic acid, m. p. 102·5° (Found: Br, 62·8. $C_{10}H_8O_2N_2Br_4$ requires Br, 63·0%). *Ethyl* 2 : 4 : 6-*tribromobenzeneazoacetoacetate*, small yellow prisms from alcohol, m. p. 96·5° (Found: Br, 50·8. $C_{12}H_{11}O_3N_2Br_3$ requires Br, 50·9%).

THE QUEEN'S COLLEGE, OXFORD. [*Received, August 18th*, 1928.]



CCCLXV.—*Metallic Derivatives of Hydroxy-esters. Part I. Copper and Nickel Derivatives of Methyl Salicylate.*

By Brian Wilfred Doak and John Packer.

The alkali salts of the complex acids theoretically derived from hydroxy-acids by the replacement (in part at least) of the hydrogen of the hydroxyl groups by various metals have been the subject of many investigations (see Wark, J., 1923, **123**, 1816, 1826; 1924, **125**, 2004; 1927, 1753, for references). It is, however, impossible to assign definite constitutional formulæ to all but the simplest of them owing to the difficulty of distinguishing between the carboxylic and the hydroxylic hydrogen atom and the extent to which each is replaced by the metal of the complex anion.

The metallic derivatives of the corresponding hydroxy-esters appear to have been little investigated. The potassium and barium derivatives of methyl salicylate and various metallic derivatives of ethyl acetoacetate have long been known; sodium and potassium metalloacetoacetates, however, are unknown. Since the completion of the present work Burrows and Wark (this vol., p. 222) have described anhydrous methyl aluminosalicylate, $Al(C_8H_7O_3)_3$, the complex aluminosalicylic acid, $H_2\left[(C_7H_4O_3)_2Al\begin{matrix}OH\\OH_2\end{matrix}\right]$, and a number of its salts: they did not succeed in preparing salts of the type $M_3[(C_7H_4O_3)_3Al]$.

It is to be expected that, as in the case of the sodium salts, the stability and ease of formation of the esters of the complex metal-substituted hydroxy-acids would be greater the more acidic the hydroxylic hydrogen atom. The esters of phenolic acids should therefore yield more stable metallic derivatives than the esters of aliphatic hydroxy-acids, and for this reason salicylic acid was chosen for investigation first. Sodium cuprisalicylate (anhydrous) has been isolated by Wark (J., 1927, 1753), who assigns to it the formula $Na_2[Cu(C_7H_4O_3)_2]$.

(I.) (II.) (III.)

Starting with methyl salicylate, the authors have prepared *methyl cuprisalicylate* and *nickelosalicylate* as crystalline dihydrates, and *anhydrous* methyl cuprisalicylate, which differs somewhat from the

hydrated form in its solubility in organic solvents. The constitutions of the hydrates are best represented as in (I; X = Cu or Ni), the two molecules of water being held by co-ordination bonds to the central copper or nickel atom, which has a co-ordination number of four. These hydrates are non-volatile solids, undergoing exothermic decomposition on heating and leaving a quantitative residue of the metallic oxide. In this respect methyl cuprisalicylate dihydrate differs from ethyl cupriacetoacetate, which is not hydrated, is volatile below its decomposition temperature, and shows considerable solubility in liquids of low dielectric constant, such as chloroform, and therefore probably is a co-ordinated copper compound possessing a chelate ring structure as shown in (II), the dotted lines denoting co-ordination bonds (the copper atom sharing a pair of electrons belonging to each carbonyl oxygen atom and thus completing its octet of electrons). The tendency of anhydrous methyl cuprisalicylate towards similar co-ordination with chelate ring formation (III) is apparently small, as shown by its relatively small, although appreciable, solubility in chloroform (in which the hydrate is, however, insoluble) and its non-volatility.

Methyl cuprisalicylate and nickelosalicylate dihydrates are completely decomposed by mineral acids. They are insoluble in cold water; but when boiled with water, methyl cuprisalicylate undergoes complete hydrolysis to methyl salicylate and copper hydroxide (or oxide), and methyl nickelosalicylate yields methyl salicylate and *methyl hydroxynickelosalicylate* (IV: X = Ni; R = H). The

(IV) $CO_2Me{\cdot}C_6H_4{\cdot}O{\cdot}X{\cdot}OR$

(V) $CO_2Me{\cdot}C_6H_4{\cdot}O{\cdot}Cu{\cdot}O{\cdot}Cu{\cdot}O{\cdot}C_6H_4{\cdot}CO_2Me$

corresponding copper compound (IV: X = Cu; R = H) can be obtained, by less energetic hydrolysis, by passing wet air over methyl cuprisalicylate dihydrate at 100°. This *methyl hydroxycuprisalicylate*, on heating at 100° in a stream of dry air, undergoes dehydration to yield the *basic compound* (V). The hydrolysis of methyl cuprisalicylate, which occurs according to the equation

$$(CO_2Me{\cdot}C_6H_4{\cdot}O)_2Cu + H_2O \rightleftharpoons CO_2Me{\cdot}C_6H_4{\cdot}OH + CO_2Me{\cdot}C_6H_4{\cdot}O{\cdot}Cu{\cdot}OH,$$

is reversible, the hydroxycuprisalicylate slowly absorbing methyl salicylate vapour at the ordinary temperature. That hydrolysis can also proceed very slowly at the ordinary temperature is shown by the facts that methyl cuprisalicylate dihydrate gradually loses weight in a vacuum (2 cm.) to an extent greatly in excess of that corresponding to the loss of its two molecules of water and that methyl cuprisalicylate and nickelosalicylate dihydrates smell quite strongly of methyl salicylate at the ordinary temperature. An

hydrous methyl cuprisalicylate, however, is stable at temperatures up to 100° in the absence of water vapour.

Methyl cuprisalicylate and nickelosalicylate dihydrates also undergo alcoholysis with methyl and ethyl alcohols. The reaction between methyl cuprisalicylate dihydrate and methyl alcohol occurs (partly at least) at the ordinary temperature, whereas that with ethyl alcohol occurs only on boiling. When boiled with methyl alcohol, both esters yield the respective *methoxymetallosalicylates* (IV: X = Cu or Ni; R = Me) as insoluble residues. The reaction

$$(CO_2Me\cdot C_6H_4\cdot O)_2X + MeOH \rightleftharpoons CO_2Me\cdot C_6H_4\cdot OH + CO_2Me\cdot C_6H_4\cdot O\cdot X\cdot OMe$$

is reversible and the insoluble methoxy-compound can readily be made to pass into methyl-alcoholic or acetone solution as the original metallosalicylate by the addition of methyl salicylate. The reversibility of this reaction is the basis of the method for the preparation of anhydrous methyl cuprisalicylate (see p. 2768).

On boiling with ethyl alcohol, methyl nickelosalicylate dihydrate gives the corresponding insoluble *ethoxy-compound* (IV: X = Ni; R = Et). Methyl cuprisalicylate dihydrate behaves differently, the alcoholysis with boiling ethyl alcohol proceeding a stage further to give small quantities of methyl salicylate and *cupric ethoxide*, $Cu(OEt)_2$. The addition of very little methyl salicylate completely suppresses the alcoholysis in this case.

These alkyloxy-derivatives are stable in the absence of moisture, even at 100°, but undergo hydrolysis in its presence, although only very slowly at the ordinary temperature. Methyl methoxycuprisalicylate, on heating at 100° in a stream of moist air, gives methyl alcohol and the same hydroxycuprisalicylate as is obtained by the hydrolysis of the original cuprisalicylate.

Direct methylation of sodium cuprisalicylate, $Cu(O\cdot C_6H_4\cdot CO_2Na)_2$ (VI), to methyl cuprisalicylate by means of methyl iodide or sulphate in non-aqueous solvents could not be effected, but the latter reagent converts sodium cuprisalicylate in aqueous or aqueous-alcoholic solution into the basic compound (V) in 70% yield. Now sodium cuprisalicylate undergoes hydrolysis in aqueous solution, as is shown by the appearance of a pale green precipitate after a very short time. If the first stage of the hydrolysis is the production of sodium salicylate and a basic compound analogous to (V) (with Na in place of Me), the formation of (V) by means of methyl sulphate can readily be understood and is in agreement with the simple constitutional formula (VI) assigned to sodium cuprisalicylate by Ward (*loc. cit.*).

When concentrated ammonia is added to alcoholic solutions (containing methyl salicylate) of methyl cuprisalicylate and methyl nickelosalicylate, ammine complexes are formed, but only *methyl diamminenickelosalicylate* has been isolated, two ammonia molecules having replaced the two water molecules of the dihydrate (I; X = Ni). This diamminenickel compound crystallises in three forms, two of which are metastable. On heating with water it undergoes rapid hydrolysis, the basic methyl hydroxynickelosalicylate (IV: X = Ni; R = H), identical with that obtained by the hydrolysis of the dihydrate (I), being produced.

Copper and nickel have a co-ordination number of four in the compounds formulated above. Burrows and Wark (*loc. cit.*) regard the aluminium atoms in methyl and ethyl aluminosalicylates and in the salts of the acid $H_2\left[(C_7H_4O_3)_2Al\begin{matrix}OH\\OH_2\end{matrix}\right]$ as having a co-ordination number of six. The latter salts, however, can be simply formulated as $(CO_2M\cdot C_6H_4\cdot O)_2Al<\begin{matrix}OH\\OH_2\end{matrix}$, according to which the aluminium atom has a co-ordination number of four. This is in agreement with the failure of Burrows and Wark to resolve the ion $\left[(C_7H_4O_3)_2Al\begin{matrix}OH\\OH_2\end{matrix}\right]''$ into optical antipodes. The dihydrates and dialcoholates of these salts can then be represented as containing aluminium of co-ordination number six. The properties of methyl aluminosalicylate, $(CO_2Me\cdot C_6H_4\cdot O)_3Al$, do not lend much support to the contention that it is definitely a stable co-ordinated compound of aluminium, although no doubt there is a tendency towards co-ordination (with the C:O of the carbomethoxy-groups) with chelate ring formation. A comparison of methyl or ethyl aluminosalicylate with ethyl aluminomalonate and of methyl cuprisalicylate with ethyl cupriacetoacetate indicates an increased tendency towards co-ordination with the formation of chelate rings on passing from the salicylate to the open-chain compounds, a tendency which is fully developed in the metallic derivatives of acetylacetone.

EXPERIMENTAL.

Methyl Cuprisalicylate Dihydrate (I; X = Cu).—Copper acetate dihydrate (36 g.; slightly less than the theoretical quantity) in aqueous solution and concentrated ammonia (16 c.c.) were added to a solution of methyl salicylate (50 g.) in about five times its volume of 94% ethyl alcohol. *Methyl cuprisalicylate dihydrate*, which rapidly crystallised, was removed, washed with 50% and finally with 80% alcohol, in which it was practically insoluble, and air-dried (yield, 67%) (Found: C, 47·8; H, 4·5; Cu, 15·8; *M*,

ebullioscopic in acetone, 397. $C_{16}H_{18}O_8Cu$ requires C, 47·8; H, 4·5; Cu, 15·8%; *M*, 401·7).

The dihydrate is a green crystalline solid, soluble in acetone (from which it may readily be recrystallised), methyl salicylate, and benzene, very slightly soluble in ether, and insoluble in chloroform. It begins to decompose at 115°, but suffers partial hydrolysis at lower temperatures owing to interaction with its water of crystallisation.

Hydrolysis. In a vacuum, methyl cuprisalicylate dihydrate lost water and methyl salicylate, very slowly at the ordinary temperature and more rapidly at 100°, but the hydrolysis was incomplete. When the dihydrate was heated in air at 100°, the hydrolysis was also incomplete owing to the escape of some of the water of crystallisation.

A stream of air saturated with water vapour was passed over methyl cuprisalicylate dihydrate heated at 100—105°. After 10 days the weight of the residual *methyl hydroxycuprisalicylate* (IV: X = Cu; R = H) was almost constant (Found: loss, 37·6. Calc. loss due to hydrolysis, 42·3%). The stream of moist air was then replaced by one of dry air; the weight again decreased and became constant after a further 6 days, the *basic compound* (V) having been formed (Found: C, 43·1; H, 3·3; Cu, 28·5. $C_{16}H_{14}O_7Cu_2$ requires C, 43·1; H, 3·2; Cu, 28·6%). The total loss in weight was 44·4% (calc., 44·6%).

Alcoholysis of Methyl Cuprisalicylate Dihydrate.—(i) *With methyl alcohol. Formation of methyl methoxycuprisalicylate* (IV: X = Cu; R = Me). When methyl cuprisalicylate dihydrate was treated with cold methyl alcohol, the green colour changed to blue; very little material dissolved, however, even on boiling. Methyl cuprisalicylate dihydrate was treated with methyl alcohol in a Soxhlet apparatus until the extract was colourless: methyl salicylate and a very little methyl cuprisalicylate dihydrate were identified in the extract. The residue after extraction was *methyl methoxycuprisalicylate* (Found in air-dried material: C, 43·9; H, 4·2; Cu, 25·9; *M*, ebullioscopic in chloroform, 238. $C_9H_{10}O_4Cu$ requires C, 43·9; H, 4·1; Cu, 25·9%; *M*, 245·6).

Methyl methoxycuprisalicylate is a blue solid, non-volatile but decomposed on heating, soluble in chloroform but insoluble in water, methyl alcohol, ether and acetone. It is decomposed by mineral acids. Boiling water completely hydrolyses it to methyl salicylate, methyl alcohol, and copper oxide, but in moist air the methoxy-group only is attacked. When heated at 100° in a stream of wet air (4 days) and thereafter in dry air (4 days), it gave successively methyl hydroxycuprisalicylate (Found: loss, 5·7. Calc.

5·7%) and the basic compound (V) (Found: total loss, 9·3. Calc., 9·4%. Found in final material: C, 43·1; H, 3·3; Cu, 28·5. Calc. for $C_{16}H_{14}O_7Cu_2$: C, 43·1; H, 3·2; Cu, 28·6%).

(ii) *With ethyl alcohol.* When methyl cuprisalicylate dihydrate was boiled with ethyl alcohol the bulk of it dissolved to give a deep green solution, but there was a small residue of *cupric ethoxide*, probably contaminated with cupric oxide (Found in air-dried material: C, 31·3; H, 6·5; Cu, 42·6. $C_4H_{10}O_2Cu$ requires C, 31·4; H, 6·6; Cu, 41·4%). On further boiling, the green solution turned brown and a small quantity of copper oxide, no doubt formed by hydrolysis by the small amount of water present, separated.

Anhydrous Methyl Cuprisalicylate.—Methyl methoxycuprisalicylate (24·5 g.) was dissolved in a solution in anhydrous acetone of the theoretical quantity of methyl salicylate (15·2 g.). Anhydrous methyl cuprisalicylate separated and was dried over calcium chloride (Found: C, 52·4; H, 4·0; Cu, 17·4. $C_{16}H_{14}O_3Cu$ requires C, 52·2; H, 3·9; Cu, 17·4%). It is a green solid which does not crystallise well, is slightly soluble in chloroform and insoluble in acetone, and gives with methyl alcohol the methoxy-derivative (IV: X = Cu; R = Me).

Methylation of Sodium Cuprisalicylate.—Sodium cuprisalicylate (5 g.), prepared by Wark's method (*loc. cit.*), was dissolved in water (50 c.c.), an excess of methyl sulphate (2 c.c.) immediately added, and the whole shaken at 40° for 15 minutes. The basic compound (V) separated as a dull green solid; it was washed with water and acetone and air-dried (Found: C, 43·0; H, 3·2; Cu, 28·6%).

Methyl Nickelosalicylate Dihydrate (I; X = Ni).—An aqueous solution of nickel chloride was added to an alcoholic solution of methyl salicylate (theoretical quantities), the whole being made neutral by the addition of concentrated ammonia solution. The *methyl nickelosalicylate dihydrate* did not crystallise nearly as readily as the copper compound and the yield was much less (Found in air-dried material: C, 48·3; H, 4·7; Ni, 14·7. $C_{16}H_{18}O_8Ni$ requires C, 48·4; H, 4·5; Ni, 14·8%).

Methyl nickelosalicylate dihydrate is a light green, crystalline substance, insoluble in water and chloroform but soluble in acetone.

Hydrolysis. When the dihydrate was boiled with water, the colour changed to a darker green and *methyl hydroxynickelosalicylate* (IV: X = Ni; R = H) was formed (Found in air-dried solid: C, 42·1; H, 3·6; Ni, 25·9. $C_8H_8O_4Ni$ requires C, 42·3; H, 3·5; Ni, 25·9%).

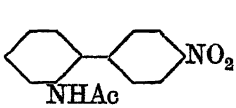
Alcoholysis. When the dihydrate was boiled with methyl or ethyl alcohol, a portion dissolved, leaving a green residue of *methyl*

methoxynickelosalicylate (IV: X = Ni; R = Me) (Found in air-dried material: C, 44·8; H, 4·2; Ni, 24·2. $C_9H_{10}O_4Ni$ requires C, 44·9; H, 4·2; Ni, 24·3%) or *methyl ethoxynickelosalicylate* (Found in air-dried material: C, 46·0; H, 4·8; Ni, 23·0. $C_{10}H_{12}O_4Ni$ requires C, 46·1; H, 4·7; Ni, 23·0%), respectively. These two substances are insoluble in acetone but soluble in chloroform.

Methyl Diamminenickelosalicylate.—When an excess of concentrated aqueous ammonia was added to a mixture of the theoretical quantities of an aqueous solution of nickel chloride and an alcoholic solution of methyl salicylate, the colour changed from green through blue to deep purple; purple octahedral crystals of *methyl diamminenickelosalicylate* slowly separated and were washed with aqueous alcohol containing ammonia and dried in an atmosphere containing ammonia (Found: C, 48·6; H, 5·2; N, 7·1; Ni, 14·8. $C_{16}H_{20}O_6N_2Ni$ requires C, 48·6; H, 5·2; N, 7·1; Ni, 14·9%). By the addition of a considerable excess of ammonia in this preparation, the diammine compound was obtained in two metastable forms, *viz.*, very fine needles and many-faced crystals of undetermined form, both of which changed fairly rapidly in contact with the solution into the stable octahedral form. Analyses of mixtures of these forms gave figures identical with the above.

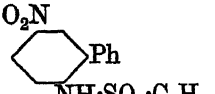
Methyl diamminenickelosalicylate is a bright purple, crystalline solid which smells slightly of ammonia and methyl salicylate on exposure to the air, is insoluble in hot or cold acetone, ether and chloroform, and is only slightly attacked by boiling methyl and ethyl alcohols, in which it is insoluble. Heated in a stream of dry air or ammonia, it lost over 40% by weight; only a portion of the ammonia present in the original diammine compound was evolved as such.

Hydrolysis. The diammine compound dissolved in cold water to give a blue (concentrated) or green (dilute) solution which was unstable owing to hydrolysis and immediately started to throw down a green, flocculent precipitate. On boiling, it gave ammonia, methyl salicylate, and a green residue of methyl hydroxynickelosalicylate (Found in the air-dried solid: C, 42·2; H, 3·6; Ni, 25·8. Calc. for $C_8H_8O_4Ni$: C, 42·3; H, 3·5; Ni, 25·9%).



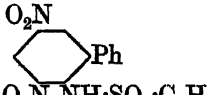
Other metallic derivatives of methyl salicylate are under investigation.

CANTERBURY COLLEGE,
UNIVERSITY OF NEW ZEALAND. [*Received, July 23rd,* 1928.]



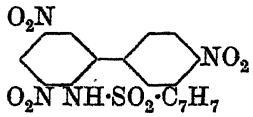
CCCLXVI.—*Investigations in the Diphenyl Series. Part VIII. Derivatives of 2-Amino- and 4-Amino-diphenyl.*

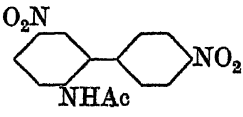
By FRANK BELL.



IN view of the anomalous nitration of 2-acetamidodiphenyl, which yields 4′-nitro-2-acetamidodiphenyl (I) as a primary product (Scarborough and Waters, J., 1927, 89), the behaviour of 2-p-*toluenesulphonamidodiphenyl* has been examined (compare J., 1926, 2708; 1927, 1129). This compound nitrates with the greatest ease first in the 5-position (II) and then in the 3-position (III). The same ease of substitution is shown by 4′-*nitro*-2-p-*toluenesulphonamidodiphenyl*, since under gentle conditions of nitration

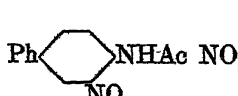
(I.)





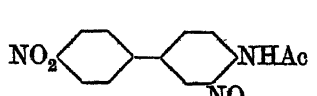
(II.)

(III.)

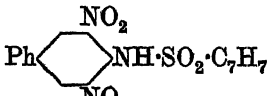


it yields the 3 : 5 : 4′-*trinitro*-derivative (IV). This behaviour is in marked contrast with that of the acetylated bases, for 5 : 4′-dinitro-2-acetamidodiphenyl (V) can be recovered unchanged after solution in fuming nitric acid. 2-Acetamidodiphenyl itself undergoes nitration less readily than 4-acetamidodiphenyl, but the introduction of a nitro-group can be effected without use of sulphuric

(IV.)



(V.)

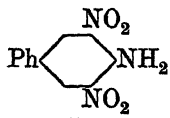


acid, and in this case the primary product is the 5-*nitro*-derivative. Further nitration of this, under all the conditions tried, gave 5 : 4′-dinitro-2-acetamidodiphenyl (V) as the only isolable product. This behaviour accords well with the nitration of 4-acetamidodiphenyl, which gives the 3-nitro-derivative (VI) as primary product and then the 3 : 4′-dinitro-derivative (VII) (Scarborough and Waters, J., 1927, 1134), and these results suggested that 4-*p*-toluenesulphonamidodiphenyl should give the 3 : 5-*dinitro*-derivative (VIII): actually it does nitrate with the utmost ease in the 3 : 5-positions.

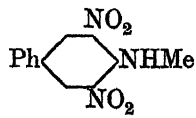
(VI.)

(VII.)

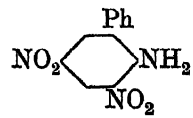
(VIII.)



This dinitro-compound (VIII) on hydrolysis readily yields the



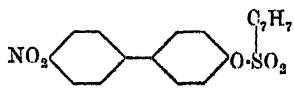
dinitro-base (IX), which is entirely different from the compound to which Fichter and Sulzberger (*Ber.*, 1904, **37**, 878) assigned this constitution. It is more highly coloured and less easily acetylated, and possesses the much greater solubility and lower melting point which compounds with groups in the 3-position invariably show when compared with compounds having the same substituents in the 4′-position.



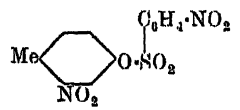
2-p-*Toluenesulphonmethylamidodiphenyl* also nitrates in the 5-position, but since compounds of this type nitrate so much less readily and quantitatively than the corresponding unmethylated derivatives, it is preferable to effect nitration before methylation.

A difficulty in acetylating amines having nitro-groups in positions adjacent to the amino-group has been noticed in this work: 3 : 5-*dinitro*-4-*aminodiphenyl* (IX) and 3 : 5-dinitro-4-methylaminodiphenyl (X) are acetylated only in the presence of sulphuric acid, and the acetyl derivative of 3 : 5-*dinitro*-2-*aminodiphenyl* (XI) has not yet been obtained.

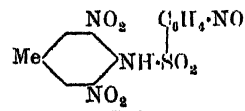
This investigation suggests that the arylsulphonyl group has a



(IX.)



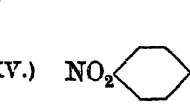
(X.)



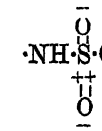
(XI.)

considerable advantage over the acetyl group for the preparation of highly nitrated amines in good yield. In higher nitrations (especially in examinations of a quantitative character) the liability of a nitro-group to enter the *p*-toluenesulphonyl residue has to be guarded against. This difficulty can be overcome by the use of the *m*-nitrobenzenesulphonyl derivative or the *p*-nitrobenzenesulphonyl derivative, which has now been made readily accessible (see p. 2776).

The nitration of the *p*-toluenesulphonyl derivative of 4-hydroxydiphenyl to give the 4′-derivative (XII) is in such marked contrast with the nitration of the corresponding derivative of 4-amino-



(XII.)

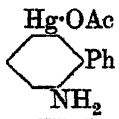


(XIII.)

(XIV.)

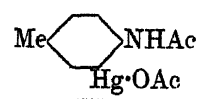
diphenyl (above) that the first use of *p*-nitrobenzenesulphonyl chloride has been made in contrasting the behaviour of the derivatives of *p*-cresol and of *p*-toluidine: p-*tolyl* p-*nitrobenzenesulphonate* nitrates in the 2-position (XIII), and p-*nitrobenzenesulphon*-*tolylamide* in the 3 : 5-positions (XIV), of the toluene [illegible] (Me = 1). That the *p*-nitrobenzenesulphonate group [illegible]

directing is shown by the nitration of *phenyl* p-*nitrobenzenesulphonate* to give the 4-*nitro*-derivative (XV).



(XV.) 

 (XVI.)



The results outlined above show the powerful orienting nature of the benzenesulphonamido-group, its weakening in the benzenesulphonmethylamido-group, and its complete overthrow in the benzenesulphonates.

It appears that the positively charged sulphur atom of the sulphonamido-group (XVI) facilitates and stabilises the adoption of a negative charge by the nitrogen atom (shown by sodium salt formation), and causes substitution to proceed as in the case of a phenol. The observed sensitiveness of the acetyl group to conditions of nitration can only be explained on the assumption that the acetamido-group enters into salt formation with a strong acid (see, *inter alia*, Dadswell and Kenner, J., 1927, 1102), being thereby converted into a very weakly orienting positive group, so that further substitution naturally resembles that of 2-nitrodiphenyl (Le Fèvre and Turner, J., 1926, 2043; Bell and Kenyon, *ibid.*, p. 2707).

The mercuration of diphenyl derivatives has been little studied, though such mercury compounds would seem to offer a ready source of substances, such as 3-bromo-4-acetamidodiphenyl, otherwise difficult to obtain. A preliminary examination has now been made. 2-Aminodiphenyl monomercurated in the 5-position (XVII), for the product after acetylation and demercuration gave 5-bromo-2-acetamidodiphenyl.

(XVII.)

(XVIII.)

(XIX.)

4-Aminodiphenyl, by analogy with its behaviour on halogenation, must mercurate in the 3-position, but the monomercuri-derivative actually obtained gave 3 : 4′-dibromo-4-acetamidodiphenyl on acetylation and demercuration, a result which is attributed to the fact that, owing to the limited solubility of the mercury compound, the treatment with bromine must take place in hot acetic acid solution.

This observation recalls the ease with which 4-acetamidodiphenyl brominates in the 4′-position (Scarborough and Waters, J., 1926,

557; Kenyon and Robinson, *ibid.*, p. 3050) and in view of the results described earlier in this paper it seemed of interest to examine the bromination of 4-*p*-toluenesulphonamidodiphenyl. Under the experimental conditions used, only the 3-*bromo*-derivative could be isolated, and in poor yield.

3-Bromo-4-hydroxydiphenyl gave a *monomercuri*-derivative, and on treatment with bromine this gave 3 : 5 : 4′-tribromo-4-hydroxydiphenyl: the tribromination of 4-hydroxydiphenyl is not easily accomplished in normal circumstances.

The preparation of the above mercurated acetanilides directed attention to the statement that aceto-*p*-toluidide on mercuration behaves abnormally in giving the anhydro-compound (XVIII) (Schrauth and Schoeller, *Ber.*, 1910, **43**, 2808). The preparation of 3-*acetoxymercuriaceto*-p-*toluidide* (XIX) both by direct mercuration and by acetylation of acetoxymercuri-*p*-toluidine is now described.

2-Aminodiphenyl appears to offer a ready means of obtaining the highly interesting hydrocarbon *o*-diphenylene (Dobbie, Fox, and Gauge, J., 1911, **99**, 683; 1913, **103**, 36) by elimination of its diazotised amino-group with copper powder (a method so successful in the preparation of fluorenone derivatives from aminobenzophenones; Ullmann and Mallet, *Ber.*, 1898, **31**, 1694). However, under the conditions of the present experiments 2-chlorodiphenyl and 2-azodiphenyl were the only isolable products.

Experimental.

2-Aminodiphenyl was prepared in 80% yield by the method of Scarborough and Waters (*loc. cit.*). West's process (J., 1925, **127**, 494) applied to 2-nitrodiphenyl gave a brown 2-aminodiphenyl in only 55% yield.

Attempted Preparation of o-*Diphenylene.*—The filtered diazo-solution prepared from 2-aminodiphenyl (17 g.) was poured into a well-stirred copper paste (from copper sulphate, 125—300 g.). From the reaction mass, by distillation in steam, a small quantity of oily 2-chlorodiphenyl was obtained which crystallised after being shaken with hydrochloric acid and with sodium hydroxide; m. p. 33° (Found: C, 76·6; H, 4·5. Calc.: C, 76·4; H, 4·8%). From the residue after steam distillation, ether extracted a gummy substance; extraction of this with cold petroleum left almost pure 2-azodiphenyl, which crystallised from petroleum in orange needles, or from a very concentrated benzene solution in garnet-red prisms, m. p. 144° (Found: C, 86·4; H, 5·7. Calc.: C, 86·2; H, 5·4%).

5-*Nitro*-2-*acetamidodiphenyl.*—To a mixture of nitric acid (*d* 1·4, 20 c.c.) and acetic acid (20 c.c.) was added 2-acetamidodiphenyl (10 g.), the temperature being kept below 30°. After ½ hour, the

solution was poured into water and the precipitated solid was removed and boiled with alcohol. The filtered solution deposited 5-*nitro*-2-*acetamidodiphenyl* in thick orange needles, m. p. 133° (Found: C, 65·3; H, 4·6. $C_{14}H_{12}O_3N_2$ requires C, 65·6; H, 4·7%).

If the temperature is allowed to rise during the nitration, there is formed in addition to the above compound a mixture of more highly nitrated products, which are readily separated owing to their sparing solubility in hot alcohol.

5-*Nitro*-2-*aminodiphenyl*, obtained by hydrolysis of its acetyl derivative with alcoholic hydrochloric acid, crystallised from alcohol in yellow needles, m. p. 125° (Found: C, 66·8; H, 4·6. $C_{12}H_{10}O_2N_2$ requires C, 67·3; H, 4·7%). The base was readily re-acetylated and converted into its *p*-toluenesulphonyl derivative by the usual methods. 5-*Nitro*-2-p-*toluenesulphonamidodiphenyl* crystallised from acetic acid in thick, pale yellow needles, m. p. 169° (Found: C, 62·2; H, 3·9. $C_{19}H_{16}O_4N_2S$ requires C, 62·0; H, 4·3%).

2-p-*Toluenesulphonamidodiphenyl*, obtained from 2-aminodiphenyl by the usual method, crystallised readily from acetic acid, alcohol, or benzene–petroleum in large rhombs, m. p. 99° (Found: C, 70·6; H, 5·3. $C_{19}H_{17}O_2NS$ requires C, 70·6; H, 5·3%). Methylation yielded 2-p-*toluenesulphonmethylamidodiphenyl*, which crystallised from alcohol in prisms, m. p. 136° (Found: C, 71·2; H, 5·8. $C_{20}H_{19}O_2NS$ requires C, 71·3; H, 5·6%).

Nitration of 2-p-*Toluenesulphonamidodiphenyl*.—(*a*) 2·5 G. were warmed on a water-bath for 7 hours with a mixture of water (25 c.c.) and nitric acid (2·5 c.c.). The product, crystallised from acetic acid, gave pure 5-nitro-2-*p*-toluenesulphonamidodiphenyl (see above).

(*b*) To 3·7 g., dissolved in acetic acid (37 c.c.) at 70°, was added nitric acid (*d* 1·5; 3 c.c.) in acetic acid (3 c.c.), and the whole was maintained at 70° for ¼ hour. On cooling, the liquid filled with prisms of 3 : 5-*dinitro*-2-p-*toluenesulphonamidodiphenyl*, m. p. 186°, unchanged after crystallisation from acetic acid (Found: C, 55·5; H, 3·8. $C_{19}H_{15}O_6N_3S$ requires C, 55·7; H, 3·6%). A solution of this compound (2 g.) in sulphuric acid (4 c.c.) was after ½ hour poured into water and neutralised with ammonia; the precipitated 3 : 5-*dinitro*-2-*aminodiphenyl* crystallised from alcohol in lustrous yellow plates, m. p. 182° (Found: C, 55·2; H, 3·6. $C_{12}H_9O_4N_3$ requires C, 55·6; H, 3·5%). This base was recovered unchanged after boiling under reflux for 2 hours with acetic anhydride alone, and in the presence of sulphuric acid only oily products were obtained.

Nitration of 2-p-*Toluenesulphonmethylamidodiphenyl*.—(*a*) This

compound (2 g.) was added to a mixture of nitric acid (*d* 1·5; 10 c.c.) and acetic acid (10 c.c.) and after 10 minutes the resultant solution was poured into water. (*b*) 3·5 G. in nitric acid (7 c.c.) were warmed on a water-bath, and the mixture poured into water. The gummy precipitate obtained by either method, when crystallised from acetic acid, furnished pure *5-nitro-2-p-toluenesulphonmethylamidodiphenyl* in rosettes of small needles, m. p. 152° (Found: C, 62·4; H, 4·4. $C_{20}H_{18}O_4N_2S$ requires C, 62·8; H, 4·7%). It was proved identical with the substance obtained by the methylation of 5-nitro-2-*p*-toluenesulphonamidodiphenyl (described above).

4′-Nitro-2-acetamidodiphenyl was prepared and hydrolysed by the method of Scarborough and Waters (*loc. cit.*). *4′-Nitro-2-p-toluenesulphonamidodiphenyl*, prepared from the base in the usual manner, crystallised from acetic acid in very pale yellow needles, m. p. 163° (Found: C, 62·0; H, 4·4. $C_{19}H_{16}O_4N_2S$ requires C, 62·0; H, 4·4%). This compound (1 g.) in warm acetic acid (10 c.c.) was treated with fuming nitric acid (1 c.c.) in acetic acid (1·5 c.c.). On cooling, the liquid filled with crystals which, recrystallised from acetic acid, gave pure *3 : 5 : 4′-trinitro-2-p-toluenesulphonamidodiphenyl* in prisms, m. p. 190° (Found: C, 49·8; H, 3·2. $C_{19}H_{14}O_8N_4S$ requires C, 49·8; H, 3·1%). This trinitro-derivative was hydrolysed by dissolving it in concentrated sulphuric acid and after ½ hour pouring the solution on ice. The precipitated *3 : 5 : 4′-trinitro-2-aminodiphenyl* crystallised from much alcohol as a bright yellow powder, m. p. 229° (Found: C, 47·7; H, 2·9. $C_{12}H_8O_6N_4$ requires C, 47·3; H, 2·6%).

5 : 4′-Dinitro-2-acetamidodiphenyl from 5-Nitro-2-acetamidodiphenyl.—To 1 g., dissolved in a mixture of sulphuric acid (3 c.c.) and acetic acid (1·5 c.c.), fuming nitric acid (0·8 c.c.) in acetic acid (1 c.c.) was added. After 12 hours, the solution was poured into water; the precipitate obtained, after being washed with alcohol, crystallised from alcohol–pyridine in prismatic needles, m. p. 208°, identical with the product obtained by the nitration of 4′-nitro-2-acetamidodiphenyl. 5 : 4′-Dinitro-2-aminodiphenyl did not react with *p*-toluenesulphonyl chloride under the ordinary conditions.

Nitration of 4-p-Toluenesulphonamidodiphenyl.—To 10 g., dissolved in acetic acid (10 c.c.) at 80°, fuming nitric acid (10 c.c.) in acetic acid (10 c.c.) was added. On cooling, pure *3 : 5-dinitro-4-p-toluenesulphonamidodiphenyl* (9·5 g.) separated; it crystallised from acetic acid in long needles, m. p. 189° (Found: C, 55·4; H, 3·7. $C_{19}H_{15}O_6N_3S$ requires C, 55·7; H, 3·6%). Hydrolysis in the usual manner gave *3 : 5-dinitro-4-aminodiphenyl*, which crystallised from benzene in orange-red needles, m. p. 177° (Found: C, 55·6; [illegible]. $C_{12}H_9O_4N_3$ requires C, 55·6; H, 3·5%). This base was not [illegible]

by acetic anhydride alone, but in the presence of sulphuric acid it gave 3 : 5-*dinitro*-4-*acetamidodiphenyl*, which crystallised from alcohol in pale yellow needles, m. p. 146° (Found : C, 55·8; H, 3·8. $C_{14}H_{11}O_5N_3$ requires C, 55·8; H, 3·6%).

3 : 5-*Dinitro*-4-p-*toluenesulphonmethylamidodiphenyl*, obtained from the corresponding base by methylation, crystallised from acetic acid in needles, m. p. 144° (Found : C, 55·9; H, 4·3. $C_{20}H_{17}O_6N_3S$ requires C, 56·2; H, 4·0%). Hydrolysis with sulphuric acid gave the already described 3 : 5-dinitro-4-methylaminodiphenyl (Bell and Kenyon, J., 1926, 2710), which with acetic anhydride, in the presence of sulphuric acid, gave 3 : 5-*dinitro*-4-*acetomethylamidodiphenyl*. This substance crystallised from alcohol in lustrous yellow needles, m. p. 149° (Found : C, 57·2; H, 4·0. $C_{15}H_{13}O_5N_3$ requires C, 57·2; H, 4·1%).

3 : 4′-*Dinitro*-4-*acetamidodiphenyl*.—4-Acetamidodiphenyl (5 g.) was added to ice-cold fuming nitric acid (15 c.c.) and after ½ hour the solution was poured on ice. The precipitate, after being washed with alcohol, crystallised from pyridine in pale yellow needles, m. p. 240°. 2 G., when heated under reflux with alcoholic hydrochloric acid (100 c.c.), rapidly dissolved to a clear solution which soon deposited orange needles of 3 : 4′-dinitro-4-aminodiphenyl, readily recrystallised from pyridine. This base did not react with *p*-toluenesulphonyl chloride under the usual conditions.

p-*Nitrobenzenesulphonyl Chloride*.—To a boiling solution of *p*-chloronitrobenzene (250 g.) in alcohol (600 c.c.) was added in portions the product obtained by fusing crystalline sodium sulphide (200 g.) and sulphur (35 g.). The mixture was heated for ½ hour and then cooled to about 50°. The solid product, after being washed with alcohol, water, and again with alcohol, was boiled with acetic acid (500 c.c.), cooled, collected, dried, and divided into 40 g. batches. Each batch was added to fuming nitric acid (10 c.c.), and the solution was warmed for 1 hour, diluted with water (500 c.c.), and filtered. The combined filtrates were evaporated almost to dryness and again after the addition of more water. The residue was neutralised with dilute aqueous ammonia, and ammonium *p*-nitrobenzenesulphonate obtained in large crystals. This ammonium salt (100 g.) was heated with chlorosulphonic acid (100 c.c.) at 100° for 1 hour, and the cooled solution poured on ice. The precipitate was collected rapidly, dried, and crystallised from benzene–light petroleum, from which *p*-nitrobenzenesulphonyl chloride separated in large prisms, m. p. 80° (yield, 70 g.).

The derivatives of this chloride crystallise with remarkable ease. By interaction with alcoholic sodium ethoxide in ethereal solution it gives *ethyl* p-*nitrobenzenesulphonate*, large plates, m. p. 91° (Found :

C, 42·1; H, 3·7. $C_8H_9O_5NS$ requires C, 41·6; H, 3·9%), and with menthol in pyridine *menthyl* p-*nitrobenzenesulphonate*, long needles, m. p. 72° (Found: C, 55·8; H, 6·7. $C_{16}H_{23}O_5NS$ requires C, 56·3; H, 6·7%). The following sulphonates and sulphonamides were obtained by interaction of the components in pyridine solution and crystallisation of the product from acetic acid.

Phenyl p-*nitrobenzenesulphonate*, needles, m. p. 114° (Found: C, 51·8; H, 3·4. $C_{12}H_9O_5NS$ requires C, 51·6; H, 3·2%). m-*Nitrophenyl* p-*nitrobenzenesulphonate*, m. p. 133° (Found: C, 44·9; H, 2·5. $C_{12}H_8O_7N_2S$ requires C, 44·5; H, 2·5%). p-*Nitrophenyl* p-*nitrobenzenesulphonate*, m. p. 156° (Found: C, 45·0; H, 2·5%).

Nitration of Phenyl p-*Nitrobenzenesulphonate*.—2·5 G. were added slowly to ice-cold fuming nitric acid (5 c.c.), and the resulting solution poured on ice. The precipitate (2·9 g., m. p. 140—150°), when crystallised from acetic acid, furnished *p*-nitrophenyl *p*-nitrobenzenesulphonate (2·4 g.).

p-*Tolyl* p-*nitrobenzenesulphonate*, m. p. 106° (Found: C, 53·7; H, 3·7. $C_{13}H_{11}O_5NS$ requires C, 53·2; H, 3·8%).

3-*Nitro*-p-*tolyl* p-*nitrobenzenesulphonate*, m. p. 136° (Found: C, 46·4; H, 2·9. $C_{13}H_{10}O_7N_2S$ requires C, 46·1; H, 3·0%).

2-*Nitro*-p-*tolyl* p-*nitrobenzenesulphonate*, m. p. 116° (Found: C, 45·9; H, 3·0%).

Nitration of p-*Tolyl* p-*Nitrobenzenesulphonate*.—4·5 G. were added to fuming nitric acid (10 c.c.) and the solution was poured on ice. The resulting precipitate (m. p. 100—110°; 3·6 g.) on crystallisation from acetic acid furnished 2-nitro-*p*-tolyl *p*-nitrobenzenesulphonate (2·5 g.).

p-*Nitrobenzenesulphon*-p-*tolylamide* has m. p. 179—180° (Found: C, 54·0; H, 3·7. $C_{13}H_{12}O_4N_2S$ requires C, 53·5; H, 4·1%). This compound (2·5 g.) and nitric acid (5 c.c.) were warmed on a steam-bath until a vigorous reaction took place. The mixture was diluted with water and the precipitate obtained, on crystallisation from acetic acid, gave p-*nitrobenzenesulphon*-3 : 5-*dinitro*-p-*tolylamide* (XIV), m. p. 185° (Found: C, 40·8; H, 3·0. $C_{13}H_{10}O_8N_4S$ requires C, 40·8; H, 2·6%), which was identified by hydrolysis to 3 : 5-dinitro-*p*-toluidine (acetyl derivative, m. p. 194°).

5-*Acetoxymercuri*-2-*acetamidodiphenyl*.—To a solution of 2-aminodiphenyl (5 g.) in alcohol (40 c.c.) was added mercuric acetate in water (40 c.c. containing acetic acid, 2 c.c.). The precipitated oil, after being dried, was warmed with acetic anhydride; the product crystallised from aqueous acetic acid in needles, m. p. 200° (Found: Hg, 43·2. $C_{16}H_{15}O_3NHg$ requires Hg, 42·7%). Treated with bromine in acetic acid, this compound gave 5-bromo-2-acetamidodiphenyl, crystallising from aqueous alcohol in long needles,

m. p. 128°, identical with the compound prepared by the method of Scarborough and Waters (*loc. cit.*).

Mercuration of 4-*Aminodiphenyl.*—Mercurated by the method described above, 4-aminodiphenyl gave a white precipitate, m. p. 167° (Found: Hg, 54·7%), which crystallised from aqueous acetic acid without change (Found: Hg, 54·8%). It appears to be the substance $C_6H_5 \cdot C_6H_3 \begin{matrix} NH \\ | \\ Hg \end{matrix}$, which requires Hg, 54·6%. Its solution in warm acetic acid, on cooling, deposited needles of 3-*acetoxymercuri*-4-*acetamidodiphenyl*, m. p. 205° (Found: Hg, 42·9. $C_{16}H_{15}O_3NHg$ requires Hg, 42·7%). On repeated crystallisation from boiling acetic acid this compound lost its crystalline character and increased in melting point and mercury content (44·1, 46·5%). The product, m. p. 205°, on treatment with bromine (1 mol.) in acetic acid gave gummy material, but with an excess of bromine it gave a compound, sparingly soluble in alcohol and crystallising from benzene in colourless needles, m. p. 196°. This must be 3 : 4′-dibromo-4-acetamidodiphenyl (Scarborough and Waters, J., 1926, 561), and the presence of this additional bromine atom accords well with the propensity of 4-acetamidodiphenyl to brominate in the 4′-position.

Bromination of 4-p-*Toluenesulphonamidodiphenyl.*—To 6 g. in warm acetic acid (50 c.c.) was added bromine (3 g.) in acetic acid (15 c.c.). After cooling, the solution was filtered from a small amount of unchanged material and poured into water. The gummy precipitate, after repeated crystallisation from alcohol, gave 3-*bromo*-4-p-*toluenesulphonamidodiphenyl* in large prisms, m. p. 119° (Found: C, 56·4; H, 4·2. $C_{19}H_{16}O_2NBrS$ requires C, 56·7; H, 4·0%). It was identical with the compound obtained by the interaction of *p*-toluenesulphonyl chloride and 3-bromo-4-aminodiphenyl in pyridine solution.

3-Bromo-4-hydroxydiphenyl furnished a uniform *monomercuri*-derivative, which crystallised from acetic acid in needles, m. p. 235° (Found: Hg, 39·7, 39·4. $C_{14}H_{11}O_3BrHg$ requires Hg, 39·5%), but 4-hydroxydiphenyl gave a mixture of more highly mercurated derivatives (Found: Hg, 61·7, 60·6. $C_{16}H_{14}O_5Hg_2$ requires Hg, 58·4%). When treated with bromine in acetic acid, these compounds all gave 3 : 5 : 4′-tribromo-4-hydroxydiphenyl.

3-*Acetoxymercuriaceto*-p-*toluidide.*—Mercuric acetate (20 g.) was added to aceto-*p*-toluidide (10 g.) in acetic acid (100 c.c.) and the solution, after boiling under reflux for 1 hour, was filtered from precipitated mercurous acetate and evaporated under diminished pressure. The residue was boiled with water and crystallised successively from aqueous alcohol, acetic anhydride, and acetic acid,

3-*acetoxymercuriaceto*-p-*toluidide* being obtained in long needles, m. p. 178° (Found: Hg, 49·3, 49·6. $C_{11}H_{13}O_3NHg$ requires Hg, 49·3%). It was more easily prepared by dissolving 3-acetoxymercuri-*p*-toluidine (m. p. 189° decomp.: obtained in quantitative yield from *p*-toluidine) in acetic anhydride, and recrystallising the product until of constant melting point. Treated with bromine in acetic acid, it gave 3-bromoaceto-*p*-toluidide contaminated by dibromoacetotoluidide.

[*Received, August 10th*, 1928.]

CCCLXVII.—*The Interaction of Bromine with Acetic Anhydride. Part IV. Bromination and Chlorination compared.*

By HERBERT BEN WATSON and EMRYS HADDON ROBERTS.

INVESTIGATION of the reactions of chlorine with acetic anhydride, acetyl chloride, and acetic acid has yielded results which indicate that chlorination is in many respects similar to bromination, but nevertheless presents some striking contrasts.

It was shown by Gal (*Ann. Chim. Phys.*, 1862, **66**, 187) that the chlorination of acetic anhydride yields acetyl chloride and monochloroacetic acid, products which are the analogues of those obtained by the action of bromine. The authors now find that the velocity curves resemble in form those obtained by Orton, Watson, and Hughes in bromination experiments (Part II, J., 1927, 2458), and that the reaction is similarly accelerated by acid chlorides, ferric chloride, sulphuric acid, and iodine or iodine chloride. That changes of an identical character take place in the two cases is proved conclusively by the constancy of the values of C obtained by use of the expression $C = 1/t \,.\, \log_e (a + P)/(a + P - x)$, which was deduced by Orton, Watson, and Hughes for bromination. It is clear, therefore, that chlorination, like bromination, proceeds by two routes, involving in the one the halogenation of the acid chloride and in the other the preliminary enolisation of the anhydride.

Chlorine, however, reacts far more slowly than bromine. The values of the constants in Tables II and III leave no doubt that this difference is due entirely to a difference in the speeds of halogenation of the acyl halides, whilst the velocity of enolisation of the anhydride is unaffected.

Quinoline, pyridine, and sodium acetate, which inhibit the bromination of acetic anhydride (Part II), have no similar effect on chlorination; the first-named two, indeed, accelerate somewhat the disappearance of chlorine. The influence of these substances on bromination has been attributed by one of us (Watson, Part III, J., 1927, 3065) to their reaction with a trace of hydrogen bromide produced in the bromination of the enolised anhydride, for by removal of the halogen acid the series of reactions involving the acid bromide will be eliminated, and in addition the speed of enolisation of the anhydride very considerably decreased. The catalytic effect of the base upon the enolisation appears to be but small in comparison with that of halogen acid.

The remarkable difference between bromination and chlorination may find an explanation in the following considerations. Acetic anhydride, in spite of its fairly high dielectric constant, behaves in all respects as a "normal" liquid (compare Jones and Betts, this vol., p. 1178; Jones, *ibid.*, p. 1195). In a medium of this type, the halogen acids are doubtless covalent compounds (compare Sidgwick, "The Electronic Theory of Valency," p. 93), and reaction with the base would consist in the giving up of a proton covalently linked to the halogen. In presence of an excess of bromine, hydrogen bromide exists almost entirely in combination as the perbromide HBr_3; the powerful electron-affinity of the two co-ordinated bromine atoms (Ingold, *Ann. Report*, 1926, 140) will bring about a loosening of the proton, thus enabling its appropriation by the base to take place readily:

$$\text{—C(—C)>N:} + \text{H:}\ddot{\text{Br}}\text{:(Br}_2\text{)} \longrightarrow \text{—C(—C)>N:H}^+ + \text{:}\ddot{\text{Br}}\text{:(Br}_2\text{)}^-.$$

An analogy, consisting in the withdrawal of a proton covalently attached to *oxygen*, is found in the production of hydroxo-ammines of cobalt and chromium by the action of pyridine or ammonia on the corresponding aquo-ammines, as exemplified in the reaction $[Cr(NH_3)_2(H_2O)_4]Cl_3 + 2C_5H_5N = [Cr(NH_3)_2(H_2O)_2(OH)_2]Cl + 2C_5H_5N,HCl$ (Werner, *Ber.*, 1907, **40**, 272, 4098, 4113, 4133; Pfeiffer, *ibid.*, p. 3129).

In the case of hydrogen chloride there is but little perhalide formation (compare the relative effects of hydrogen bromide and chloride on the bromination and chlorination, respectively, of acetanilide: Orton and Jones, *Brit. Assoc. Rep.*, 1910, 99); weakening of the covalent bond does not therefore occur, and the base has no opportunity of combining with the proton. The hydrogen chloride is thus free to react with a molar quantity of acetic anhydride: $HCl + (CH_3{\cdot}CO)_2O \rightleftharpoons CH_3{\cdot}COCl + CH_3{\cdot}CO_2H$; the chlorin-

ation of the acid chloride then proceeds, and, moreover, the enolisation of the anhydride is catalysed not only by the small quantity of halogen acid present in the above equilibrium but also by the base. Chlorination is therefore not inhibited but accelerated, and the larger the quantity of base introduced the greater is the acceleration.

Acetyl nitrate has been shown to inhibit very powerfully the bromination of acetic anhydride, by oxidation of halogen acid (Parts II and III). As would be expected from the relative indifference of hydrogen chloride to oxidising agents, it does not inhibit chlorination. Addition of a little nitric acid, in fact, accelerates the reaction, an effect which indicates incomplete conversion of the acid into acetyl nitrate.

Chlorination of Acetyl Chloride.—The relatively slow speed of chlorination of acetyl chloride, which is indicated by the experiments described in the foregoing, has been confirmed by an examination of the reaction of chlorine at 25° with the acid chloride itself. Acetyl chloride, in fact, reacts with chlorine more slowly than with bromine (see Table IV). Contrary to expectation, the rate of disappearance of chlorine has been found to *increase* as the reaction proceeds. This peculiarity is not the result of a comparatively rapid substitution of a second hydrogen atom, since chloroacetyl chloride does not react with chlorine appreciably at 25°, but it is due rather to side reactions, which consist, partly at least, in the replacement of the carbonyl oxygen by two atoms of chlorine, followed by further chlorination of the $C_2H_3Cl_3$ to give hexachloroethane, the odour of which is unmistakable in the product (compare the action of phosphorus pentachloride on acetyl chloride: Hübner, *Annalen*, 1861, **120**, 330; Hübner and Müller, *Z. Chem.*, 1870, 328).

Addition of a small quantity of iodine catalyses the production of chloroacetyl chloride so powerfully (compare Jazukowitsch, *Z. Chem.*, 1868, 234) that the side reactions are now imperceptible, and the velocity is proportional to the concentration of chlorine. The side reactions are masked in the same manner when acetyl chloride reacts with chlorine in acetic anhydride medium (preceding section).

Chlorination of Acetic Acid.—A study of the reaction of chlorine with acetic acid at 100° has yielded results resembling those previously obtained by one of us for bromination (Watson, J., 1925, **127**, 2067); the reaction, however, is slower. A powerful acceleration results from the introduction of a small quantity of acetyl chloride, to which the catalytic influence of acetic anhydride (Hentschel, *Ber.*, 1884, **17**, 1286) and also that of phosphorus

and phosphorus pentachloride (Brückner, *Z. angew. Chem.*, 1927, **40**, 973) are doubtless to be ascribed (compare the interpretation of the effects of acetic anhydride and phosphorus on bromination: Watson, *loc. cit.*). The velocity is proportional to the quantity of acetyl chloride added, and different acid chlorides have identical effects.

These facts lead to the conclusion that chlorination proceeds through a series of reactions analogous to those suggested for bromination (Watson, *loc. cit.*), *viz.*,

$$CH_3{\cdot}COCl + Cl_2 = CH_2Cl{\cdot}COCl + HCl,$$
$$CH_2Cl{\cdot}COCl + CH_3{\cdot}CO_2H = CH_3{\cdot}COCl + CH_2Cl{\cdot}CO_2H,$$

preceded, when the chloride of another acid is added initially, by

$$R{\cdot}COCl + CH_3{\cdot}CO_2H = CH_3{\cdot}COCl + R{\cdot}CO_2H.$$

In presence of an acid bromide, the velocity of *bromination* of acetic acid has been shown to vary directly as the concentration of the halogen, and this is in harmony with the mechanism suggested. A similar relationship is not found in the analogous case of chlorination in presence of an acid chloride, for the velocity of the reaction decreases less rapidly than does the concentration of chlorine. This observation is accounted for, however, by the existence of the side reactions referred to in the preceding section.

Hydrogen chloride accelerates the chlorination of acetic acid, and its influence is probably due to the production of a trace of acid chloride (compare the effect of hydrogen bromide on bromination: Watson, *loc. cit.*). The powerful enolising agents sulphuric acid and ferric chloride, on the other hand, have very little effect, a fact which indicates that reaction of the halogen with the enolic form of acetic acid occurs only to a very small extent. The part played by the enolide, though insignificant, may perhaps contribute to some extent to the absence (noted above) of a simple relation between the fall in concentration of chlorine and the velocity. In bromination, its effect is masked by the relatively great speed of the reaction of bromine with acetyl bromide, or is perhaps to some extent balanced by perbromide formation.

Inactivity of Iodine.—Iodine does not attack acetic anhydride at 25°, nor does introduction of hydrogen iodide or of sulphuric acid lead to reaction. On heating the anhydride with iodine at 100° for several hours there is little fall in iodine concentration but some carbonisation (compare Gal, *loc. cit.*). No reaction takes place when acetic acid is heated with iodine at 100°.

EXPERIMENTAL.

The acetic anhydride was obtained by fractional distillation of "reagent" material. The acid chlorides and other substances

employed were purified as described in the earlier papers of this series. Each reaction mixture (25 c.c.) contained 5 c.c. of a solution of chlorine in carbon tetrachloride; in preparing this solution, chlorine from a cylinder was passed through water, permanganate, and sulphuric acid and then into the solvent. The velocity measurements were carried out at 25° in well-stoppered flasks as described previously, 2 c.c. being withdrawn for each titration. The anhydride was used throughout in large excess. Titres are stated in c.c. of *N*/10-thiosulphate.

The reaction of bromine with acetic anhydride at 25°, when carried out under the same conditions as the above (5 c.c. of carbon tetrachloride in 25 c.c. of reaction mixture), gave the following:

Initial titre.	Fall in titre after (hours) 1.	2.	3.	4.	5.
11·60	0·75	3·10	6·05	8·40	10·50

Comparison with the figures recorded in Part II for the bromination of pure acetic anhydride shows the very marked retardation produced by the carbon tetrachloride (compare Watson, this vol., p. 1138).

Reaction of Halogens with Acetic Anhydride and Excess of Acyl Halide.—As in the above experiments, 25 c.c. of reaction mixture contained 5 c.c. of a solution of the halogen in carbon tetrachloride. Titres are stated in c.c. of $N/50$-thiosulphate, and time in minutes. The constants are calculated from the formula $C = 1/t \cdot \log_e(a + P)/(a + P - x)$ (Part II), where $C = k$[acyl halide] and $C' = k'[Ac_2O]$, k and k' being the velocity coefficients for the halogenation of the acyl halide and the enolisation of the anhydride, respectively, and $P = C'/C$.

TABLE II.

Chlorine and Excess of Acetic Anhydride and Acetyl Chloride.

$[Ac_2O] = 6{\cdot}376M$, [AcCl] $= 2{\cdot}915M$, $P = 1{\cdot}10$.

$a = 0{\cdot}1215M$.			$a = 0{\cdot}0344M$.

40	4·05	0·0403	20	3·82	0·0391
	Mean	0·0390		Mean	0·0385

$k = 0{\cdot}0132$, $C' = 0{\cdot}0001125$, $k' = 0{\cdot}0000180$.

The values of k' are in excellent agreement in the two sets of experiments.

Chlorination of Acetyl Chloride.—The distillation of the acid chloride and the velocity measurements (for which 5 c.c. of the solution of chlorine in carbon tetrachloride were added to 25 c.c. of acetyl chloride) were carried out in the apparatus described by one of us (Watson, this vol., p. 1139). The acetyl chloride was

throughout in large excess. The velocity of bromination under identical conditions is given for comparison. Titres are expressed in c.c. of $N/10$-thiosulphate.

Chlorination of Acetic Acid.—The acetic acid was purified by the method of Orton and Bradfield (J., 1927, 983). It melted at 16·45°, was stable to halogens at the ordinary temperature, and gave results identical with those obtained by use of the best Kahlbaum acid. A solution of chlorine in this acid was used in making up the reaction mixtures, which were heated in sealed tubes at 100° in portions of 2 c.c. The acetic acid was throughout in large excess. Titres are stated in c.c. of $N/10$-thiosulphate.

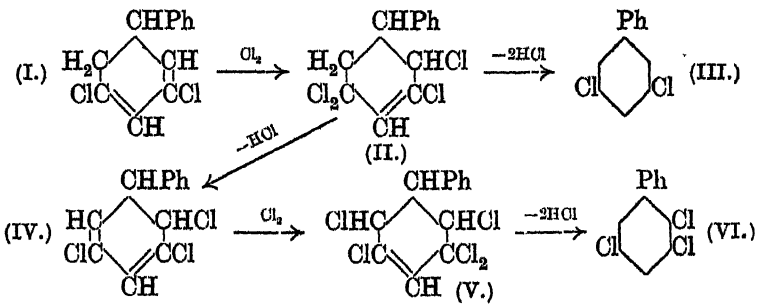
CCCLXVIII.—*Conversion of Hydroaromatic into Aromatic Compounds. Part III.* 3 : 5-*Dichloro*-1-*phenyl*-$\Delta^{2:4}$-cyclo*hexadiene and its Behaviour with Chlorine.*

By LEONARD ERIC HINKEL and DONALD HOLROYDE HEY.



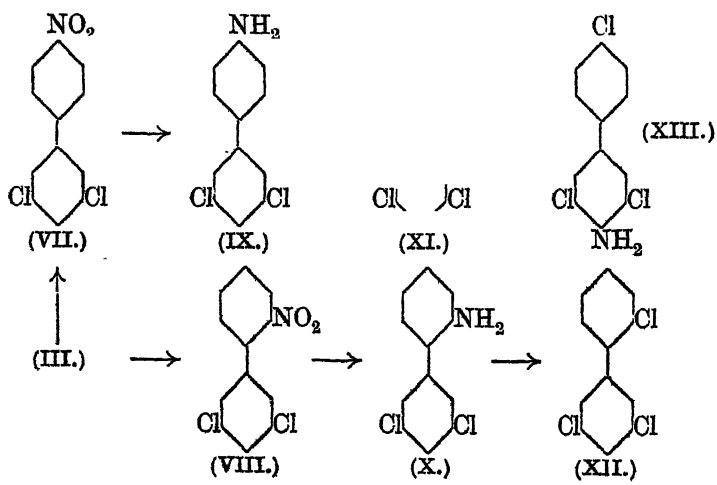
IN previous papers (J., 1924, **125**, 1847; this vol., p. 1200) it has been shown that halogenated derivatives of phenyldihydroresorcinol are converted into aromatic compounds much more readily than the corresponding derivatives of dimethyldihydroresorcinol. For instance, 4 : 5 : 5-tribromo-1-phenyl*cyclo*hexan-3-one readily yields an aromatic compound directly, whereas 4 : 5 : 5-trichloro-1 : 1-dimethyl*cyclo*hexan-3-one only does so through the stable intermediate 4 : 5-dichloro-1 : 1-dimethyl-Δ^5-*cyclo*hexen-3-one; and 4 : 5 : 5 : 6-tetrabromo-1-phenyl*cyclo*hexan-3-one yields 4 : 5-dibromo-3-hydroxydiphenyl directly, whereas 4 : 5 : 5 : 6-tetrachloro-1 : 1-dimethyl*cyclo*hexan-3-one readily changes into the stable intermediate 4 : 5 : 6-trichloro-1 : 1-dimethyl-Δ^5-*cyclo*hexen-3-one. Moreover, cleavage of the ring by hydrolysis cannot be achieved in dimethyldihydroresorcinol, but can be readily effected in the case of phenyldihydroresorcinol (Vorländer, *Annalen*, 1897, **294**, 317; *Ber.*, 1894, **27**, 2057; compare also Crossley, J., 1901, **79**, 138).

The greater readiness with which the derivatives of phenyldihydroresorcinol are converted into aromatic compounds is only to be expected, since in the one case the transformation necessitates the migration of a methyl group, whereas in the other the more mobile hydrogen atom is involved, and this is further borne out in the present investigation on 3 : 5-*dichloro*-1-*phenyl*-$\Delta^{2:4}$-cyclo*hexadiene* (I).

Knoevenagel (*Ber.*, 1894, **27**, 2337) isolated a liquid impure dichlorophenyl*cyclo*hexadiene by the action of phosphorus pentachloride (2 mols.) on phenyldihydroresorcinol, but the structure he assigned to it is no longer tenable (compare Crossley and Le Sueur, J., 1902, **81**, 821). Since both di- and tri-methyldihydroresorcinols on treatment with phosphorus pentachloride give, in addition to a dichloro*cyclo*hexadiene, 3 : 5-dichloro-*o*-xylene and 3 : 5-dichloro-1 : 2 : 6-trimethylbenzene, respectively (Crossley and Le Sueur, J.

1902, **81**, 1533; Crossley and Hills, J., 1906, **89**, 875), 3 : 5-dichlorodiphenyl (III) should in like manner be formed during the action of phosphorus pentachloride on phenyldihydroresorcinol. This has now been shown to be the case. The main product of the action, however, is 3 : 5-dichloro-1-phenyl-$\Delta^{2:4}$-*cyclo*hexadiene (I). This compound readily absorbs chlorine, and the *tetrachloro*-compound (II) produced rapidly loses hydrogen chloride (2 mols.) on warming, giving an 80% yield of 3 : 5-dichlorodiphenyl (III). The constitution of (III) has been established by its synthesis as carried out by Scarborough and Waters (J., 1927, 89), who describe it as an oil. The compound has now been obtained by both methods as a crystalline solid.

When an excess of chlorine is passed into a hot solution of 3 : 5-dichloro-1-phenyl-$\Delta^{2:4}$-*cyclo*hexadiene in chloroform, in addition to 3 : 5-dichlorodiphenyl, a small quantity of 2 : 3 : 5-*trichlorodiphenyl* (VI) is produced, the constitution of which has been confirmed by its synthesis from 3 : 5-dichloro-2-aminodiphenyl. Its formation is explained in the following manner. Loss of one molecule of hydrogen chloride from the tetrachloro-compound (II) gives the trichloro-compound (IV). This may partly lose hydrogen chloride to give 3 : 5-dichlorodiphenyl or may further combine with chlorine, giving an unstable pentachloro-compound (V), which readily loses hydrogen chloride to give 2 : 3 : 5-trichlorodiphenyl (VI) (compare Crossley, J., 1904, **85**, 264; Hinkel, J., 1920, **117**, 1296).



In marked contrast with the action of chlorine on 3 : 5-dichloro-1 : 1-dimethyl-$\Delta^{2:4}$-*cyclo*hexadiene (Hinkel, *loc. cit.*), which gives rise to a pentachlorodimethyl*cyclo*hexene in addition to the two trichloro-*o*-xylenes and tetrachloro-*o*-xylene, no such higher chlorinated products could be obtained in the present investigation. The course of the reactions during the two chlorinations again reveals the influence of the phenyl group in a remarkable manner. In the derivatives of phenyldihydroresorcinol the group ·CCl:CH·CCl_2· (compounds II and V), although unsaturated, does not further combine with chlorine, whereas in the corresponding derivatives of dimedone

dihydroresorcinol further chlorination readily occurs, producing more highly chlorinated derivatives. Since the transformation from the hydroaromatic series yields diphenyl derivatives with substituents in only one of the two rings, such reactions serve as a convenient method for the preparation of diphenyl derivatives of this type.

The separation of the chlorodiphenyls (III) and (VI) obtained as described above is conveniently effected by regulated oxidation with chromic and acetic acids, which converts the dichlorodiphenyl into 3 : 5-dichlorobenzoic acid : the stability of the diphenyl nucleus to oxidation by chromic acid is increased by the introduction of negative substituents, even although these are all in the same ring. A separation may also be effected by means of their nitro-derivatives.

Nitration of 3 : 5-dichlorodiphenyl gives chiefly 3 : 5-*dichloro*-4′-*nitrodiphenyl* (VII) with a smaller quantity of 3 : 5-*dichloro*-2′-*nitrodiphenyl* (VIII). On prolonged boiling (16 hours) with chromic and acetic acids the former gives a small quantity of *p*-nitrobenzoic acid and 3 : 5-dichloro-2′-nitrodiphenyl partly decomposes completely and partly remains unattacked. That in both compounds the nitro-group is in the ring not containing the chlorine atoms is shown by (*a*) oxidation of the corresponding *amines* (IX and X) giving 3 : 5-dichlorobenzoic acid and (*b*) the chlorine atoms being inert towards piperidine (see Le Fèvre and Turner, J., 1927, 1113; this vol., p. 247). The identity of 3 : 5-dichloro-4′-nitrodiphenyl was proved by reduction and conversion of the base into a *trichlorodiphenyl* (XI), m. p. 88°, which was identical with the compound obtained by the elimination of the amino-group from 3 : 5 : 4′-trichloro-4-aminodiphenyl (XIII). The isomeric dichloronitrodiphenyl gave a *trichlorodiphenyl* melting at 58° (XII).

Nitration of 2 : 3 : 5-trichlorodiphenyl readily gives a mononitro-compound which, owing to its exceptional stability towards oxidation by chromic acid and its inertness towards piperidine, is regarded as 2 : 3 : 5-*trichloro*-4'-*nitrodiphenyl*.

These results of substitution are in agreement with the tentative rules that have been proposed for the orientation of substituents in the diphenyl series (Scarborough and Waters, J., 1926, 557; Blakey and Scarborough, J., 1927, 3000).

EXPERIMENTAL.

Action of Phosphorus Pentachloride on Phenyldihydroresorcinol.—Phenyldihydroresorcinol (94 g.; 1 mol.) was suspended in 200 c.c. of dry chloroform, and phosphorus pentachloride (220 g.; in excess of 2 mols.) gradually added; after an hour the reaction was completed by gentle warming. The chloroform was removed under reduced pressure, and the residue poured on ice and extracted with ether. From the extract, washed with 10% sodium hydroxide solution and with water and dried, 3 : 5-*dichloro*-1-*phenyl*-$\Delta^{2:4}$-cyclo*hexadiene* (I) (70 g.) was obtained as a colourless oil, b. p. 156°/10 mm. (Found: Cl, 31·2. $C_{12}H_{10}Cl_2$ requires Cl, 31·55%), and also 3 : 5-dichlorodiphenyl, b. p. 166°/10 mm., m. p. 36° (Found: Cl, 31·8. Calc.: Cl, 31·8%).

Action of Chlorine on 3 : 5-*Dichloro*-1-*phenyl*-$\Delta^{2:4}$-cyclo*hexadiene*. —(1) *At room temperature*. Chlorine was slowly passed for 2 hours into a solution of 65 g. of 3 : 5-dichloro-1-phenyl-$\Delta^{2:4}$-*cyclo*hexadiene in 50 c.c. of dry chloroform cooled by water. After the evolution of hydrogen chloride had ceased, the chloroform was removed on a boiling water-bath, and the residue left for several days in a vacuum over solid sodium hydroxide. The solution was distilled under reduced pressure and two fractions were collected: (i) b. p. 164—166°/9 mm. (52 g.) and (ii) b. p. 166—200°/9 mm. (14 g.). The main fraction solidified in a freezing mixture, and crystallisation from cold alcohol gave 3 : 5-dichlorodiphenyl as snow-white needles which, alone or mixed with the synthetic product obtained from 3 : 5-dichloro-2-aminodiphenyl (Scarborough and Waters, J., 1927, 89), melted at 36°. Oxidation with chromic and acetic acids gave 3 : 5-dichlorobenzoic acid (m. p. 183°). Fraction (ii) was added to the fractions obtained from the chlorination at the higher temperature.

(2) *In hot solution*. A rapid stream of chlorine was passed into a hot solution of 3 : 5-dichloro-1-phenyl-$\Delta^{2:4}$-*cyclo*hexadiene (56 g.) in dry chloroform (60 c.c.) until the copious evolution of hydrogen chloride had ceased and the solution had regained normal temperature. After removal of the chloroform, the oily residue was

tilled under reduced pressure and three fractions were collected, b. p. 170—175°, 175—180°, and 180—200°/10 mm., respectively. The fraction of b. p. 170—175°/10 mm. (35 g.) gave mainly 3 : 5-dichlorodiphenyl on redistillation. The fraction of b. p. 180—200°/10 mm. was boiled for 6 hours with an excess of chromic acid in glacial acetic acid solution. The solid obtained by dilution with water, after crystallising several times from aqueous alcohol, gave 2 : 3 : 5-trichlorodiphenyl in small, white needles which, alone or mixed with the trichlorodiphenyl obtained from 3 : 5-dichloro-2-aminodiphenyl (Scarborough and Waters, *loc. cit.*) by the Sandmeyer reaction, melted at 41° (Found : Cl, 41·4. $C_{12}H_7Cl_3$ requires Cl, 41·35%). A small quantity of 3 : 5-dichlorobenzoic acid was obtained from the mother-liquor. Treatment of the fraction of b. p. 175—180°/10 mm. in like manner also gave 2 : 3 : 5-trichlorodiphenyl.

Action of Nitric Acid on the Fraction of b. p. 175—180°/10 *mm.*—5 G. of the fraction, dissolved in glacial acetic acid, were gradually treated with 25—30 c.c. of nitric acid (*d* 1·51). The solution, after being warmed, was poured into water and the solid which separated was crystallised repeatedly from alcohol. A small quantity of 2 : 3 : 5-trichloro-4′-nitrodiphenyl and mainly 3 : 5-dichloro-4′-nitrodiphenyl were isolated from the less soluble portions, and concentration of the mother-liquor yielded a small quantity of 3 : 5-dichloro-2′-nitrodiphenyl.

Nitration of 3 : 5-*Dichlorodiphenyl.*—5 G. of 3 : 5-dichlorodiphenyl, dissolved in 12 c.c. of glacial acetic acid, were nitrated by the gradual addition of 50 c.c. of a mixture of equal volumes of fuming nitric and glacial acetic acids. The solid which separated after the addition of water was crystallised from alcohol, 3 : 5-*dichloro*-4′-*nitrodiphenyl* being obtained in small, faintly yellow needles, m. p. 146° (Found : Cl, 26·6. $C_{12}H_7O_2NCl_2$ requires Cl, 26·5%). 3 : 5-*Dichloro*-2′-*nitrodiphenyl* separated from the mother-liquor and on recrystallisation was obtained in needles, m. p. 75° (Found : Cl, 26·4%).

3 : 5-*Dichloro*-4′-*aminodiphenyl.*—2 G. of 3 : 5-dichloro-4′-nitrodiphenyl, dissolved in 30 c.c. of alcohol, were reduced with 10 g. of stannous chloride in 10 c.c. of concentrated hydrochloric acid. The mixture was heated for several hours on the water-bath and, after evaporation of the alcohol, the *base*, liberated by addition of sodium hydroxide solution, was extracted with ether; it crystallised from aqueous alcohol in flat acicular plates, m. p. 124° (Found : Cl, 29·9. $C_{12}H_9NCl_2$ requires Cl, 29·8%). 3 : 5-*Dichloro*-4′-*acetamidodiphenyl*, prepared from the base in the usual manner, crystallised from alcohol in small white needles, m. p. 188° (Found : Cl, 25·5. $C_{14}H_{11}ONCl_2$ requires Cl, 25·4%).

3 : 5-*Dichloro*-2'-*aminodiphenyl*, obtained from the corresponding nitro-compound by reduction with stannous chloride in alcoholic solution as described above, separated from aqueous alcohol in needles, m. p. 74° (Found : Cl, 29·8%). Acetylation gave 3 : 5-*dichloro*-2'-*acetamidodiphenyl*, which crystallised from alcohol in small acicular plates, m. p. 163° (Found : Cl, 25·6%).

3 : 5 : 4'-*Trichlorodiphenyl*.—4 G. of 3 : 5-dichloro-4'-aminodiphenyl were diazotised in hydrochloric acid solution at 0° and then treated with cuprous chloride solution in the usual manner. On distillation with steam 3 : 5 : 4'-*trichlorodiphenyl* was obtained which separated from alcohol in white glistening needles, m. p. 88° (Found : Cl, 41·3. $C_{12}H_7Cl_3$ requires Cl, 41·35%).

3 : 5 : 2'-*Trichlorodiphenyl*.—4 G. of 3 : 5-dichloro-2'-aminodiphenyl were diazotised and treated as described above. The product crystallised from alcohol in faintly yellow needles, m. p. 58° (Found : Cl, 41·4%).

Nitration of 2 : 3 : 5-*Trichlorodiphenyl*.—Fuming nitric acid was gradually added to a solution of 2 : 3 : 5-trichlorodiphenyl in glacial acetic acid. 2 : 3 : 5'-*Trichloro*-4'-*nitrodiphenyl*, obtained by diluting the solution with water, crystallised from alcohol in long, yellow needles, m. p. 155° (Found : Cl, 35·1. $C_{12}H_6O_2NCl_3$ requires Cl, 35·2%).

UNIVERSITY COLLEGE, SWANSEA. [*Received, July 24th*, 1928.]

CCCLXIX.—*A Study in the Formation of Gels. Vulcanised Oils.*

By B. C. J. G. KNIGHT and P. STAMBERGER.

IT has been shown (Stamberger, *Rec. trav. chim.*, 1927, **46**, 837; 1928, **47**, Oct. 15) that an insoluble, tough, elastic substance is formed by heating triolein with sulphur. The process may be divided into three stages : (1) Combination of the triolein with sulphur; (2) polymerisation of these molecules to double molecules; (3) further polymerisation giving the elastic substance. From the reaction mixture may be separated an acetone-soluble portion corresponding to stage 1, and a benzene-soluble portion (stage 2). The remaining highly polymerised product is insoluble.

Further information has now been obtained on the processes concerned by two methods : (*a*) *X*-ray examination of the products; (*b*) examination of the behaviour of the soluble products when spread as thin films on a water surface.

EXPERIMENTAL.

For convenience the details of the various products which have been examined are given in Table I.

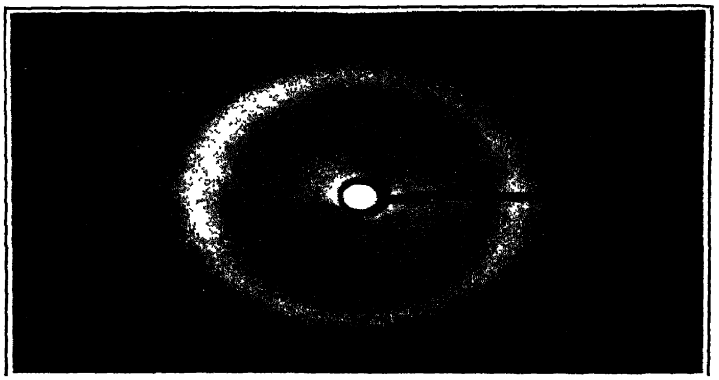


TABLE I.

The *X*-ray diagrams were obtained by the method described by Katz (*Z. Physik*, 1927, **45**, 100) with Cuα rays. All the products gave circles of the same diameter (Figs. 1*a* and *b*), which is calculated for a distance of 40 mm. between the substance and the photographic plate, and shown in Table I; these circles indicate an amorphous structure. The *X*-ray examination did not show any change in the molecules in the different stages of the reaction.

Unimolecular Films.—The soluble products and the sulphur-containing oleic acid obtained by cold saponification have been found to give unimolecular films of the expanded type when spread on water. The films of these substances have been studied by using the apparatus and technique of Adam (*Proc. Roy. Soc.*, 1926, *A*, **110**, 423). Dilute benzene solutions of known concentration of the several products were prepared. Known weights of these solutions were placed upon a clean water surface in a Langmuir–Adam trough by means of a capillary drop-pipette. The force of compression acting on the film when the area was diminished was measured by means of Adam's torsion apparatus (*loc. cit.*).

The results of the measurements are given in Figs. 2 and 3, where the compressing force (*F* in dynes/cm.) is plotted against the thickness of the film (in Ångström units). The molecular weights of the substances cannot be accurately determined, as they are not sharply defined chemical compounds. We have preferred, therefore, to plot the thickness of the film as calculated from its area, the weight of substance, and its specific gravity (*d* in Table I), rather than the area per molecule. In Table II are collected the values for the dimensions of the molecules derived

from the curves. The areas per molecule have been calculated approximately, assuming theoretical molecular weights derived from the sulphur content and the cryoscopic measurements.

Sulphurised oleic acid	16·9	16	96
Sulphurised oleic acid	18·5	1	86

Discussion.

It is of interest to correlate the observations made in the above experiments with the physical properties of these substances and with the appearance of elastic properties.

The combination with sulphur in the first part of the reaction does not alter the mode of orientation, and only very slightly affects the dimensions of the molecule. The film of the acetone-soluble product is about 1 Å.U. thicker at zero pressure than that of triolein, indicating that the hydrocarbon chains are tending to be oriented more nearly perpendicular to the water surface. The position of the sulphur in the molecule is not definitely determined. Most probably it is in a chain connecting the double bonds of the

FIG. 3.

adjacent oleic acid chains, since after saponification most of the sulphur is still attached to the fatty acids. About 16·5% of the sulphur is found with the glycerol after saponification, not as inorganic sulphur. Cryoscopic determinations on these sulphur-containing fatty acids show that they are still combined in groups of three. The acetone-soluble product of the first stage of the reaction is a viscous fluid substance having no elastic properties.

In the second stage of the reaction the molecules polymerise first to double molecules. This is the benzene-soluble part, and is a viscous, pasty fluid substance, slightly elastic. This substance

changed to a still more elastic sticky solid on standing for 3—4 months in a closed weighing bottle. This change could be accelerated by heating or by irradiation with ultra-violet light. An elastic solid was also obtained by keeping the benzene-soluble part under water or acetone for several days. These solid products only swelled in benzene at room temperature, but could be dissolved on continued boiling. It appears probable that the highly polymerised or aggregated molecules of the elastic solid obtained from the benzene-soluble part in this manner had been broken down by the hot solvent to double molecules. All these benzene-soluble products gave the same results on spreading on water. The thickness of the film was about the same as that of the acetone-soluble part. The area per molecule at zero pressure, calculated from the theoretical molecular weight (cryoscopic measurements and sulphur content), was twice that of the acetone-soluble part. This indicates that the double molecules are formed by the joining of two molecules side by side. The polar glyceryl groups are apparently unaltered, since the orientation is unaffected.

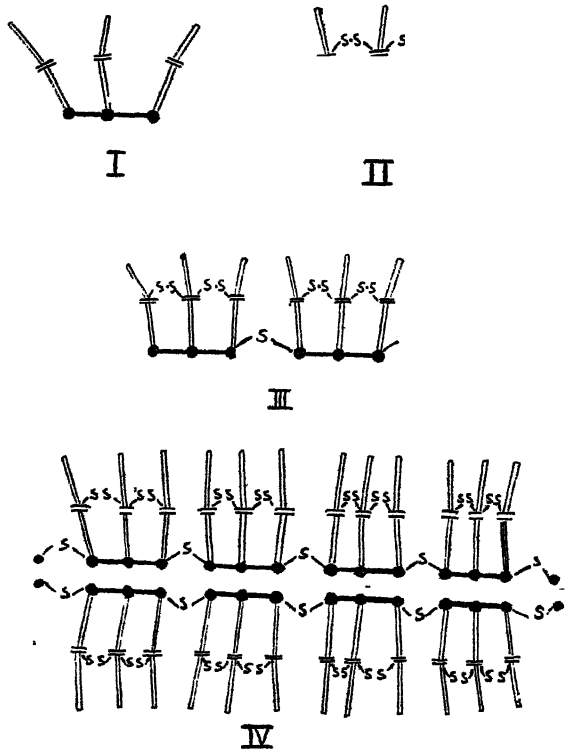
By careful heating with benzene for 2 days at a temperature not higher than 60°, the elastic polymerised product obtained from the benzene-soluble part (I) (by standing for 3—4 months at room temperature) could be completely dissolved. Cryoscopic measurement showed a very high molecular weight, at least 7000. This product (benzene-soluble, III) gave, on spreading, a film 16·3 Å.U. thick—again a unimolecular film. The slightly greater thickness of this film may be due to the polymerisation to larger groups of molecules (at least 7) causing closer packing of the fatty-acid chains. The form of the compression curve at low pressures shows that the film is there much less expanded (see Fig. 2).

The same elastic polymerised product was nearly completely dissolved on being kept under benzene at room temperature for 14 days. This solution gave no freezing-point depression even at a concentration of 7%. Accurate figures for the film thickness cannot be given owing to traces of substance being undissolved. Several measurements gave values for the thickness of 17 Å.U. at zero pressure, showing at least that the film is still one molecule thick. These measurements show that the higher molecular aggregates are formed by the linking of several molecules side by side, repeating the method of formation of the double molecules.

After saponification the elastic properties of the solid disappear. The sulphurised oleic acid is a viscous liquid. Moreover, no elastic substance could be obtained by heating oleic acid with sulphur. The sulphurised acids obtained by both methods gave films of the

same thickness, a little thicker than oleic acid. Since the fatty acids are in groups of three after saponification of both the benzene-soluble part and the elastic solid (see Stamberger, *loc. cit.*), it seems that the polymerisation is not caused by sulphur linking together hydrocarbon chains of adjacent molecules, but rather suggests that the glyceryl portion of the molecules takes part in the combination to give the elastic solid. If this is broken by saponification, the elastic properties disappear, although the fatty acids are still held together in groups of three.

The effect of lowering the temperature is interesting (see Fig. 3). A change from 16° to 1° has very little effect on the area of the oleic acid film, but this may be subjected to a somewhat higher pressure at the lower temperature before collapsing. The oleic acid film at 0° is still considerably above its temperature of transition from the expanded to condensed type of film as shown by Adam (*Proc. Roy. Soc.*, 1926, *A*, **112**, 362). On the other hand, an equal lowering of temperature causes a considerable decrease in the film of the sulphurised oleic acid. It is evident that at 1° the latter film is much nearer to its transition temperature than is oleic acid : it is approaching the behaviour of the corresponding saturated fatty acid film. The sulphurised oleic acid is less compressible than oleic acid. These differences in behaviour are undoubtedly due to the fact that in the former substance the fatty-acid chains are held together by sulphur, the double bonds being partially saturated. The molecules are thus oriented more in the manner of a condensed film.



It is now possible to suggest a theory of the formation of the final insoluble, elastic substance. The double molecules of the benzene-soluble substance have been shown to be formed by the linking together, side by side in a definite orientation, of two single molecules. The more highly polymerised product containing at least 7 molecules (benzene-soluble, III, fairly elastic) is formed by the linking of further molecules in the same manner. This combination is between the glyceryl parts of the molecules. It seems probable, therefore, that in the final insoluble elastic product there would be long chains of molecules oriented with respect to one another side by side, with their hydrocarbon chains more or less parallel, combined by a repetition of this process.

This conception of the structure leading to the formation of the insoluble elastic substance is illustrated by the diagrams in Fig. 4. On this hypothesis, the slow change of the viscous fluid to an elastic solid may be explained by the slow orientation of the molecules to give long chains. The acceleration by heating and by ultra-violet irradiation is then due to the increased number of effective collisions,

and therefore of opportunities for linking and orientation, under these conditions.

McBain has reached somewhat similar conclusions in the case of the formation of soap jellies from solution (Alexander, "Colloid Chemistry," p. 141); he says "The conclusion seems inevitable that the actual colloidal particles are the same in solution and in the true jelly, but that in the jelly the particles of neutral colloid are

FIG. 4.

I. Triolein. *III. Benzene-soluble part (I and II).*
II. Acetone-soluble part. *IV. The elastic solid.*

linked together probably to form innumerable ultramicroscopic filaments."

In a later paper (*J. Amer. Chem. Soc.*, 1927, **49**, 2230), in order to explain the observed surface concentration found to be in excess of that required for a complete unimolecular film, McBain has put forward a theory of chains of oriented molecules extending downwards from the surface of solutions of non-electrolytes. He points out that the effect of finely ground fillers upon the strength and

resiliency of rubber may be explained by this conception. The extensive surface of the finely ground filler has the rôle of orienting molecules in contact with it, and the chain effect extends with diminishing intensity into the surrounding rubber. Our view, that the increase of elasticity in the vulcanisation of triolein is due to a vectorial orientation of molecules, is in agreement with McBain's theory.

Recently, Sheppard and Keenan (*Nature*, 1928, **121**, 982) have given some interesting data for the spreading of cellulose esters on mercury. In order to explain the thinness of the films they suggest that a polymeric chain or sheet is formed one molecule thick. For this type of molecule the orientation is apparently with the chains parallel to the surface.

Summary.

1. The entrance of sulphur into triolein in vulcanisation does not change its orientation on water, and only very slightly alters the dimensions of the molecule. Elastic substances can be obtained from this product.

2. Measurements of thin films show that, in the polymerisation to such elastic substances, the molecules are linked side by side in a definitely oriented manner in long chains.

3. This work provides a basis for a theory of elastic formation in a solid.

Our best thanks are due to Prof. F. G. Donnan for criticisms and suggestions, and to Prof. J. C. Drummond for allowing the work on the films to be carried out in his department. This opportunity is taken of thanking Dr. N. K. Adam for much help when the torsion apparatus was under construction. Acknowledgment is also made to the Department of Scientific and Industrial Research for a grant held by one of us (B. C. J. G. K.).

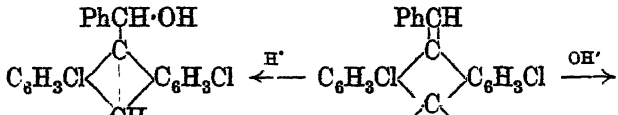
UNIVERSITY COLLEGE, LONDON. [*Received, August 2nd*, 1928.]

CCCLXX.—*Transannular Anionotropic Migrations.*

By JAMES WILFRED COOK.

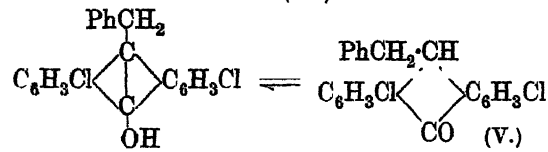
IT has been shown (Barnett, Cook, and Matthews, *Ber.*, 1927, **60**, 2353) that the monobromo-derivative of 1 : 5-dichloro-9-benzylanthracene exhibits dual properties inasmuch as it yields two distinct series of hydroxy-, acetoxy-, methoxy-, and ethoxy-compounds by suitable treatment, *viz.*, (*a*) yellow and fluorescent

compounds which are represented by formula (I) and (*b*) colourless and non-fluorescent isomeric compounds, obtained when the hydrogen bromide formed by the reaction is removed as rapidly as it is produced, which pass into their yellow isomerides under the influence of hydrogen ions. Moreover, both hydroxy-compounds are converted by hydrogen bromide into the original bromo-compound. Barnett and Matthews (*loc. cit.*) suggested tentatively that the colourless compounds have endocyclic structures (II), whereas the author (Cook, *Ber.*, 1927, **60**, 2366) regarded this as improbable and assigned a benzylidene structure (III) to the colourless compounds, postulating a migration of X to account for the interconversion of compounds of the two series :



The present communication deals with attempts to decide between structures (II) and (III); it is not claimed that the endocyclic structure (II) is definitely disproved, but there is much new evidence to substantiate structure (III) for the colourless compounds.

The analogy existing between the tautomeric system contained in a 9-alkyl derivative of anthracene (the " bridge " being regarded as equivalent to an ethylenic bond) and the simpler 3-carbon system has been established by the interconversion of 1 : 5-dichloro-10-phenyl-9-methylanthracene and the pseudo-tautomeric methylene compound (Barnett and Cook, *Ber.*, 1928, **61**, 314), and the postulated change (III)⟶(I) is then seen to be comparable with the bromine migrations in simpler conjugated systems recently studied by Farmer, Laroia, Switz, and Thorpe (J., 1927, 2937) * and Farmer, Lawrence, and Thorpe (this vol., p. 729) * and with the mobile anion tautomeric changes described by Burton and Ingold (this vol., p. 904).*

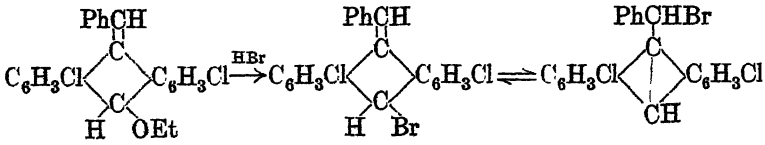


The suggestion was made tentatively (Cook, *loc. cit.*) that the rearrangement in the anthracene series is preceded by ionic dissociation, and this mechanism has been confirmed in the case of the α-phenylallyl system by the experiments of Burton (this vol., p. 1650). The order of mobility of the anions (Br>OAc> OH or OR), identical with that observed by Burton and Ingold in their compounds, is further evidence of the ionic nature of

* Other examples of mobile anion tautomerism may be found from the references given in these papers.

the migrations and it is also significant that, whereas hydrogen ions promote hydroxyl migration in the colourless hydroxy-compound (IV), hydroxyl ions bring about hydrogen migration. The 1 : 5-dichloro-9-benzylanthrone (V) resulting from the latter change was identified by direct comparison with an authentic sample and also by conversion into 1 : 5-dichloro-9-benzyl-10-phenylanthracene by treatment with magnesium phenyl bromide, followed by dehydration of the resulting carbinol.

(IV.)

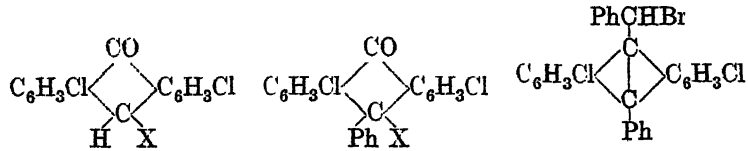


(V.)

This prototropic change, effected by brief boiling with sodium hydroxide solution, is comparable with analogous changes in open-chain systems (Burton and Ingold, *loc. cit.*).

More definite evidence that the substituent group in the colourless compounds is attached to the 10-carbon atom of the anthracene ring is afforded by an experiment carried out with the 1 : 5-dichloro-10-ethoxy-9-benzylidene-9 : 10-dihydroanthracene * (VI) prepared by Barnett (unpublished work) by the action of magnesium benzyl chloride on 1 : 5-dichloroethoxyanthrone and dehydration of the resulting dihydroanthranol. This ethoxy-compound (VI) is different from the colourless ethoxy-compound previously prepared (Barnett, Cook, and Matthews, *Ber.*, 1927, **60**, 2361) and is presumably its geometrical isomeride. It has not been possible to effect its direct conversion into the ω-ethoxy-compound, the reaction with alcoholic hydrogen chloride being slow and incomplete. This difference in migratory power between the two geometrical isomerides is curious and may be compared with a similar difference observed with the 1 : 2-dibromides of the two stereoisomeric hexatrienes (Farmer, Laroia, Switz, and Thorpe, J., 1927, 2942). The desired conversion was obtained through the bromo-compound, replacement of the ethoxy-group by the more mobile bromine atom by treatment of (VI) with hydrogen bromide leading to the same monobromo-

* I am indebted to Dr. E. de Barry Barnett for his kindness in giving me a few grams of this benzylidene compound.—J. W. C.

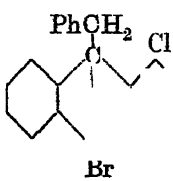


compound (VII) as was obtained by bromination of 1 : 5-dichloro-9-benzylanthracene.

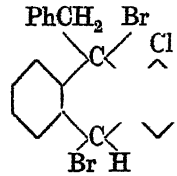
(VI.) (VII.) (VIII.)

The inversion of geometrical configuration evidently proceeds through the tautomeric phase (VIII), it having been shown already that (VIII) cannot be isolated owing to the ease with which it passes into its isomeride of the " colourless " type (Barnett, Cook, and Matthews, *loc. cit.* Compare Barnett, Cook, and Ellison, this vol., p. 889).

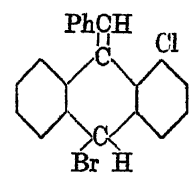
It should be possible to obtain evidence of structure (III) for the colourless compounds by oxidation to the anthrone derivative (IX).



(IX.) (X.) (XI.)

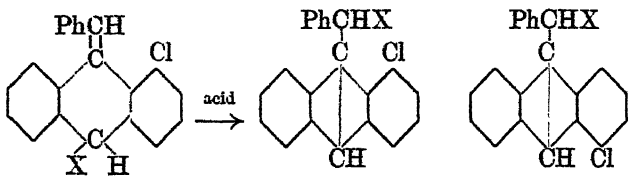


As long as there is a mobile hydrogen atom this course is not practicable on account of the ease with which the enol is oxidised. If the mobile hydrogen atom is replaced by a phenyl group, enolisation is no longer possible, so that the phenylanthrone derivative (X) should be capable of isolation from the oxidation products. With this object in view the preparation of a series of derivatives of 1 : 5-dichloro-9-benzyl-10-phenylanthracene was initiated. The substance gave a reactive *monobromo*-derivative, but the *hydroxy*- and *ethoxy*-compounds obtained from it by treatment with aqueous acetone and ethyl alcohol, respectively, in the presence of calcium carbonate were obviously of the " yellow " and fluorescent type, and this, coupled with the deep orange colour of the bromo-compound, renders it fairly certain that the latter has structure (XI). The influence of replacement of hydrogen by phenyl on the equilibrium of the anionotropic system is explicable on the electronic hypothesis of Burton and Ingold and steric influences would operate in the same direction.



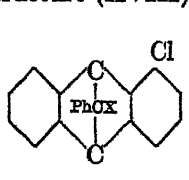
The problem was attacked from another standpoint by attempting the preparation of colourless series of derivatives from 1-*chloro*-9-*benzylanthracene* and 4-*chloro*-9-*benzylanthracene*. If the end

cyclic structure were correct, the molecule would be symmetrical and these two series of compounds would have identical structures (XII). Now, although 1 : 5-dichloro-9-benzylanthracene gives a reactive bromo-derivative, 9-benzylanthracene yields only the 10-bromo-derivative (Cook, J., 1926, 2161. Compare *Ber.*, 1927, **60**, 2366), so that the first possible pitfall was that a single α-chlorine atom might fail to have the necessary influence on the bromination. Actually, 1-chloro-9-benzylanthracene on bromination yielded a very unstable dibromide which decomposed into a mixture of the 10-*bromo*-compound (XIII; 30%) and the *benzylidene* compound (XIV; 70%):

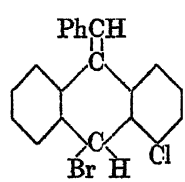


(XIII.)

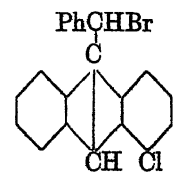
(XIV.)



From the reactive bromo-compound (XIV) derivatives were obtained of both "colourless" (XV) and "yellow" (XVI) types.



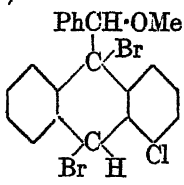
(XV.) (XVI.) (XVII.)

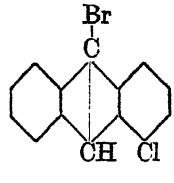


(X = OH, O·COMe or OR.)

The unstable dibromide of 4-chloro-9-benzylanthracene gave only the reactive *bromo*-compound, but this passed into "yellow" substitution products (XVII) even in the presence of calcium carbonate and it seems fairly certain in this case that the ω-bromo-compound is the stable tautomeride, so that the bromo-compound has structure (XVIII).

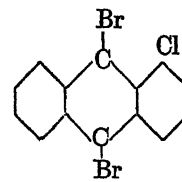
(XII.)





(XVIII.)

The steric effect of the α-chlorine atom can account for these differences between the 1-chloro- and the 4-chloro-derivatives of 9-benzyl-



anthracene. The non-formation of colourless derivatives of the 4-chloro-compound has prevented definite refutation of the endocyclic structure. It is certain, however, that the endocyclic compounds were not formed as intermediate products in the preparation of the ω-derivatives of 4-chloro-9-benzylanthracene, since the latter substances were quite different from the isomeric ω-derivatives obtained from 1-chloro-9-benzylanthracene.

The proof of the structure assigned to the "yellow" compounds is similar to that previously advanced in the case of the 1 : 5-dichloro-compounds. For instance, 4-chloro-ω-methoxy-9-benzylanthracene gave an unstable dibromide which spontaneously decomposed into benzaldehyde and 4-chloro-9-bromoanthracene (XIX):

(XIX.)

(XX.)

This new bromo-compound was identical with the substance obtained by Barnett and Matthews (*Rec. trav. chim.*, 1924, **43**, 535) by thermal decomposition of α-chloroanthracene dibromide, and the present result determines the orientation of their compound. 4-Chloro-9-bromoanthracene is stable in the presence of excess of bromine, thus resembling 1 : 5-dichloro-9-bromoanthracene (Barnett, Cook, and Matthews, *loc. cit.*), but differing from 9-bromoanthracene itself which is readily brominated. 1-Chloro-9-bromoanthracene appears to resemble 9-bromoanthracene, since it was not isolated from the decomposition products of the dibromide of 1-chloro-ω-methoxy-9-benzylanthracene, only the dibromo-compound (XX) being obtained. The bromine necessary for bromination of the monobromo-compound was evidently obtained by partial loss of bromine from the original dibromide of the methoxybenzyl compound. The difference in behaviour between the isomeric α-chloro-9-bromoanthracenes may again be attributed to the steric effect of the α-chlorine atom, provided it is assumed that bromination is preceded by 9 : 10-addition of bromine, as is certainly the case with the bromination of many other anthracene derivatives.

The ω-*methoxy*-derivative of 1-chloro-9-benzylanthracene was converted by hydrogen bromide into the "colourless" bromo-compound (XIV), so that, as in the 1 : 5-dichloro-series, the "benzylidene" bromo-compound is the stable tautomeride, whereas in the hydroxy-, *acetoxy*-, and alkoxy-derivatives the ω-structure is

the more stable. This curious difference, in conjunction with the fact that the ω-bromo-derivative of 4-chloro-9-benzylanthracene is the stable tautomeride, is doubtless due to steric factors. Thus, the omega structure is normally the stable type, but the presence of the chlorine atom in position 1 hinders the attachment of such a bulky group as bromine to the ω-carbon atom. It is perhaps significant that the bromine atom tends to take up a position as remote as possible from the α-chlorine atom (XIV and XVIII) and it may be that this is partly determined by polar factors.

It has been shown (Cook, J., 1926, 2161) that the action of excess of bromine on 10-bromo-9-benzylanthracene results in addition to one of the *Bz* rings with the formation of a tetrabromide. When 1-chloro-10-bromo-9-benzylanthracene (XIII) was treated with excess of bromine a tetrabromide was not obtained, the only product isolated being 4-chloro-9-bromoanthracene (XIX). At present it is not proposed to discuss this apparent replacement of a benzyl group by a hydrogen atom by means of bromine.

EXPERIMENTAL.

Prototropic Rearrangement of 1 : 5-*Dichloro*-10-*hydroxy*-9-*benzylidene*-9 : 10-*dihydroanthracene* (IV).—The hydroxy-compound (5 g.) was added to a solution of alcoholic sodium hydroxide prepared from sodium (5 g.) and 95% alcohol (125 c.c.). A deep blood-red colour was developed on boiling and the boiling was continued for ½ hour. The resinous product, obtained by dilution with water, was recrystallised twice from ethyl acetate and then formed colourless crystals (1·5 g.) which melted at 169—170° alone or when mixed with 1 : 5-dichloro-9-benzylanthrone (V). The identification was completed by treatment with magnesium phenyl bromide, dehydration of the resulting dihydroanthranol yielding 1 : 5-dichloro-9-benzyl-10-phenylanthracene, m. p. 211—212° (alone or mixed with an authentic sample).

The corresponding ethoxy-compound was recovered unchanged after boiling for 7 hours with alcoholic sodium hydroxide.

Action of Hydrogen Bromide on 1 : 5-*Dichloro*-10-*ethoxy*-9-*benzylidene*-9 : 10-*dihydroanthracene* (VI).—This ethoxy-compound (m. p. 170°; 1·5 g.), one of the products of the action of magnesium benzyl chloride on 1 : 5-dichloro-10-ethoxy-9-anthrone (see footnote on p. 2800) and shown to be different from the original colourless ethoxy-derivative of 1 : 5-dichloro-9-benzylanthracene, was dissolved in toluene (10 c.c.), and hydrogen bromide passed through the boiling solution for 20 minutes. After cooling and dilution with light petroleum, crystals separated which, after recrystallisation from benzene–light petroleum, melted at 180—182° alone or mixed

with the monobromo-derivative obtained from 1 : 5-dichloro-9-benzylanthracene. The identification of the bromo-compound was completed by its conversion into the original colourless ethoxy-compound by means of alcohol in the presence of calcium carbonate. The new ethoxy-compound of Barnett was thus indirectly converted into its geometrical isomeride.

Derivatives of 1 : 5-*Dichloro*-9-*benzyl*-10-*phenylanthracene.*

(a) *ω-Bromo-derivative* (XI).—A solution of 1 : 5-dichloro-9-benzyl-10-phenylanthracene (16 g.) in carbon disulphide (100 c.c.) was treated slowly at the ordinary temperature with bromine (2 c.c.). After 3 hours the solvent was removed by distillation; the residual resin, when treated with ether, became solid. The product crystallised from benzene–ether in orange crystals, m. p. 179—180° (Found: Cl + Br, 30·6. $C_{27}H_{17}Cl_2Br$ requires Cl + Br, 30·7%).

(b) *ω-Hydroxy-derivative.*—The bromo-compound (XI; 5 g.) was heated on the water-bath for 4 hours with calcium carbonate (1 g.) and acetone (60 c.c.) diluted with water (15 c.c.). The product was recrystallised twice from benzene–light petroleum and twice from benzene–alcohol and then formed canary-yellow nodules, m. p. 189—191° (Found: C, 75·1; H, 4·3. $C_{27}H_{18}OCl_2$ requires C, 75·5; H, 4·2%). Solutions of the substance had a blue fluorescence.

(c) *ω-Ethoxy-derivative.*—The bromo-compound (XI; 5 g.) was heated on the water-bath for 2 hours with ethyl alcohol (50 c.c.). The crude product, m. p. 150—155°, was repeatedly crystallised from benzene–alcohol until it melted constantly at 173—174° (Found: C, 75·9; H, 4·85. $C_{29}H_{22}OCl_2$ requires C, 76·1; H, 4·8%). This *ethoxy*-compound formed glistening yellow leaflets, fluorescent in solution, and the same result was obtained when the reaction was carried out in the presence of calcium carbonate.

α-Chloro-9-benzylanthracenes.

1-*Chloro*-9-*benzylanthracene.*—1-Chloro-9-anthrone (30 g.), obtained by reducing α-chloroanthraquinone with aluminium and sulphuric acid (Eckert and Tomaschek, *Monatsh.*, 1918, **39**, 839; compare Barnett and Matthews, J., 1923, **123**, 2550), was added slowly to a Grignard solution prepared from benzyl chloride (42 c.c.) and magnesium powder (9 g.), the solution being cooled in a freezing mixture. After 4 hours the suspension was poured on ice and ammonium chloride, the ethereal solution washed, and the ether removed by distillation. The viscous residue was treated with light petroleum, and the resulting solid (40 g.) twice recrystallised

from benzene–light petroleum (Found: C, 78·6; H, 5·4. $C_{21}H_{17}OCl$ requires C, 78·6; H, 5·3%). *1-Chloro-9-hydroxy-9-benzyl-9 : 10-dihydroanthracene* forms a colourless crystalline powder, m. p. 126—127°. It was dehydrated by allowing its solution in acetic acid containing hydrochloric acid to stand over-night at the ordinary temperature. The resulting *1-chloro-9-benzylanthracene*, recrystallised from benzene–alcohol, formed pale yellow nodules, m. p. 119—120° (Found: C, 83·5; H, 5·05. $C_{21}H_{15}Cl$ requires C, 83·3; H, 5·0%).

4-Chloro-9-benzylanthracene was obtained in good yield in exactly the same way from 4-chloro-9-anthrone, prepared by reducing α-chloroanthraquinone with tin and hydrochloric acid (Barnett and Matthews, J., 1923, **123**, 2550). The crude dihydroanthranol was not purified but was converted into the chlorobenzylanthracene, pale yellow needles from ethyl acetate–alcohol, m. p. 120° (Found: Cl, 11·8. $C_{21}H_{15}Cl$ requires Cl, 11·7%).

Bromination. Each α-chloro-9-benzylanthracene (15 g.) was dissolved in carbon disulphide (50 c.c.) and the solution, cooled in a freezing mixture, was treated with bromine (2·5 c.c.). The bromine was taken up without evolution of hydrogen bromide and in each case a solid additive compound separated, which passed into solution with liberation of hydrogen bromide on warming to the ordinary temperature. After an hour the solvent was removed by distillation, the residual oil treated with light petroleum, and the resulting yellow solid collected and dried. The crude product from 1-chloro-9-benzylanthracene was obviously a mixture. A little was dissolved in boiling pyridine, alcohol added to the solution, and the resulting *1-chloro-10-bromo-9-benzylanthracene* (XIII) recrystallised from ethyl acetate; it then formed yellow silky needles, m. p. 160° (Found: C, 66·0; H, 3·8. $C_{21}H_{14}ClBr$ requires C, 66·1; H, 3·7%). The constitution assigned to this bromo-compound depends upon its inert character, the substance being recovered unchanged after boiling for an hour with acetic anhydride containing sodium acetate or with alcoholic potassium hydroxide solution.

When the bromo-compound (XIII) was treated with excess of bromine (2 mols.) in carbon disulphide solution the bromine was slowly taken up with liberation of hydrogen bromide. After 12 hours the solvent was distilled off and the viscous residue triturated with a little ether. A solid remained which, recrystallised from ethyl acetate–alcohol, melted at 149—150° alone or mixed with 4-chloro-9-bromoanthracene (XIX) (Found: C, 57·3; H, 2·9. Calc.: C, 57·6; H, 2·75%).

1-Chloro-10-bromo-9-benzylidene-9 : 10-dihydroanthracene (XIV).—This was the chief product of the bromination of 1-chloro-9-benzyl-

anthracene, but could not be isolated from the crude mixture on account of its reactive nature. It was obtained, however, when hydrogen bromide was conducted through a boiling solution of 1-chloro-ω-methoxy-9-benzylanthracene (see below; 4 g.) in benzene (10 c.c.) for 15 minutes. The *bromo*-compound was obtained by adding light petroleum to the cooled solution and after recrystallisation from benzene–light petroleum formed almost colourless needles, m. p. 151—153° (Found: C, 66·1; H, 3·9. $C_{21}H_{14}ClBr$ requires C, 66·1; H, 3·7%). There can be no doubt that this compound was identical with the reactive bromo-compound present in the crude bromination mixture of 1-chloro-9-benzylanthracene, since by heating with methyl alcohol and calcium carbonate it was converted into the same colourless methoxy-compound as was obtained from the original bromination mixture. This mode of preparation of the pure bromo-compound (XIV) lends support to the hypothesis that in solution it is in tautomeric equilibrium with 1-chloro-ω-bromo-9-benzylanthracene (compare the equilibrium VII ⇌ VIII).

4-*Chloro*-ω-*bromo*-9-*benzylanthracene* (XVIII) appeared to be the only isomeride formed by brominating 4-chloro-9-benzylanthracene. After recrystallisation from benzene–light petroleum it formed deep yellow nodules, m. p. 165—166° (Found: C, 66·2; H, 3·8. $C_{21}H_{14}ClBr$ requires C, 66·1; H, 3·7%).

"*Colourless*" *Derivatives of* 1-*Chloro*-9-*benzylanthracene.*

In all experiments with the bromo-compound (XIV) the crude mixture of isomerides obtained by brominating 1-chloro-9-benzylanthracene was used. The products (XV and XVI) obtained from (XIV) were usually very soluble in most solvents and remained in solution, the sparingly soluble 10-bromo-compound (XIII) being filtered off. The proportion of the latter compound isolated was consistently 30% of the crude mixture.

1 - *Chloro* - 10 - *hydroxy* - 9 - *benzylidene* - 9 : 10 - *dihydroanthracene* (XV; X = OH).—The mixed bromo-compounds (5 g.) were heated on the water-bath for 4 hours with acetone (60 c.c.), water (15 c.c.), and calcium carbonate (1 g.). After cooling, the 10-bromo-compound (XIII) was filtered off, the acetone distilled from the filtrate, and the resinous product recrystallised twice from benzene–light petroleum and once from toluene. The substance then formed a colourless crystalline powder, m. p. 185°, which, like the analogous 1 : 5-dichloro-compound (IV), gave an intense orange-red colour with boiling alcoholic potassium hydroxide solution (Found: C, 79·3; H, 4·8. $C_{21}H_{15}OCl$ requires C, 79·1; H, 4·7%).

The corresponding *acetoxy*-compound (XV; X = O·CO[illegible]

obtained when a solution of this hydroxy-compound (3 g.) in pyridine (10 c.c.) was treated for 6 hours at the ordinary temperature with acetic anhydride (5 c.c.). It formed colourless glistening crystals, m. p. 151—153°, from ethyl acetate–alcohol (Found: C, 76·3; H, 4·8. $C_{23}H_{17}O_2Cl$ requires C, 76·6; H, 4·7%).

1-Chloro-10-methoxy-9-benzylidene-9 : 10-dihydroanthracene (XV; X = OMe).—The mixed bromo-compounds (3·5 g.) were heated on the water-bath for an hour with methyl alcohol (100 c.c.) in the presence of calcium carbonate (1 g.). After cooling, the filtered solution was concentrated and diluted with water. The resinous product was dried and recrystallised twice from benzene–light petroleum and then formed colourless glistening needles, m. p. 129—130°. Its solutions were non-fluorescent (Found: C, 79·3; H, 5·2. $C_{22}H_{17}OCl$ requires C, 79·4; H, 5·1%).

The corresponding ethoxy-compound could not be obtained solid.

"Yellow" Derivatives of 1-Chloro-9-benzylanthracene.

1-Chloro-ω-methoxy-9-benzylanthracene (XVI; X = OMe).—The colourless methoxy-compound (above; 0·8 g.) was heated on the water-bath for 1½ hours with methyl alcohol (15 c.c.) containing concentrated hydrochloric acid (1 c.c.). After cooling, the solid was collected and recrystallised from alcohol; it then formed pale yellow needles, m. p. 135—136°. The solutions had a strong violet fluorescence and the m. p. was depressed by admixture with the original colourless methoxy-compound (XV) or with the methoxy-derivative obtained from 4-chloro-9-benzylanthracene (XVII) (Found: C, 79·4; H, 5·2. $C_{22}H_{17}OCl$ requires C, 79·4; H, 5·1%).

Bromine (0·3 c.c.) was added to a solution of this methoxy-compound (1·85 g.) in carbon disulphide (5 c.c.), cooled in a freezing mixture. The bromine was taken up but no hydrogen bromide was evolved. The addition of light petroleum resulted in the separation of a colourless solid, which was collected and, without purification, dissolved in boiling benzene. The solution became yellow and hydrogen bromide was evolved. After boiling for ½ hour, the solution was treated with alcohol and cooled, and the resulting crystals were recrystallised from ethyl acetate (Found: C, 45·3; H, 2·1. $C_{14}H_7ClBr_2$ requires C, 45·3; H, 1·9%). *1-Chloro-9 : 10-dibromoanthracene* (XX) forms slender orange-yellow needles, m. p. 159—161°.

1-Chloro-ω-acetoxy-9-benzylanthracene (XVI; X = O·COMe).—(*a*) A solution of the mixed bromo-compounds (5 g.) and sodium acetate (3 g.) in glacial acetic acid (35 c.c.) was boiled for an hour, cooled, and filtered from the 10-bromo-compound (XIII), and the

filtrate poured into water. The precipitate was collected, dried, and recrystallised from benzene–light petroleum and then from alcohol. The *acetoxy*-compound formed yellow prisms, m. p. 157—158°, and the m. p. was depressed by admixture with the isomeric colourless acetoxy-compound (XV) or with the acetoxy-derivative of 4-chloro-9-benzylanthracene (XVII) (Found: C, 76·4; H, 4·8. $C_{23}H_{17}O_2Cl$ requires C, 76·6; H, 4·7%).

(*b*) A solution of the colourless hydroxy-compound (XV; X = OH) (0·5 g.) in acetic acid (2 c.c.) and acetic anhydride (2 c.c.) was boiled for an hour, cooled, and diluted with alcohol. The yellow crystalline product melted at 157—158° alone or mixed with a sample of the acetoxy-compound prepared as described under (*a*).

This acetoxy-compound appeared to be readily hydrolysed by alcoholic potassium hydroxide, but the resulting hydroxy-compound could not be obtained crystalline on account of its excessive solubility.

Derivatives of 4-Chloro-9-benzylanthracene.

4-Chloro-9-benzylanthracene-ω-pyridinium Bromide (XVII; X = C_5H_5NBr).—A solution of the ω-bromo-compound (XVIII) in pyridine was heated on the water-bath for a few minutes and cooled and the solid in suspension was collected, washed with pyridine and with ether, dried, and recrystallised from alcohol–ether. The *salt* formed a yellowish crystalline powder, m. p. 220—225° (decomp.) after sintering and darkening at 215° (Found: Cl + Br, 25·2. $C_{26}H_{19}NClBr$ requires Cl + Br, 25·1%).

4-Chloro-ω-hydroxy-9-benzylanthracene (XVII; X = OH).—(*a*) The ω-bromo-compound (XVIII) was hydrolysed by heating with aqueous acetone in the presence of calcium carbonate in the same way as the isomeric 1-chloro-compound (p. 2807). The *hydroxy*-compound, thrice recrystallised from benzene–light petroleum, formed a yellowish crystalline powder, m. p. 98—100° (Found: C, 79·5; H, 5·1. $C_{21}H_{15}OCl$ requires C, 79·1; H, 4·7%).

(*b*) A solution of the ω-bromo-compound (XVIII; 3 g.) and sodium acetate (3 g.) in glacial acetic acid (25 c.c.) was boiled for ½ hour, and the cooled solution poured into water. The precipitated acetate, which could not be obtained crystalline, was hydrolysed with potassium hydroxide (5 g.) in alcoholic solution at the ordinary temperature. The product, twice recrystallised from benzene–light petroleum, melted at 98—100° alone or mixed with the hydroxy-compound prepared as described under (*a*). This second method of preparation suggests that the hydroxy-compound is the ω-hydroxy-compound, a hypothesis which is supported by the fluorescence and yellow colour of the substance and also by the

fact that it gave no red colour with boiling alcoholic potassium hydroxide solution (compare p. 2807). Methylation with methyl-alcoholic hydrochloric acid yielded the methoxy-compound described below.

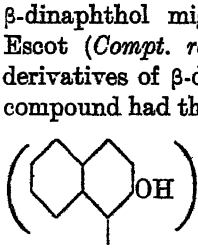
4-Chloro-ω-acetoxy-9-benzylanthracene (XVII; X = O·COMe).—The hydroxy-compound described in the preceding paragraph was acetylated in the usual manner with pyridine–acetic anhydride at 100°, and after recrystallisation from benzene–light petroleum and from methyl alcohol the product formed pale yellow nodules, m. p. 129—130° (Found: C, 76·5; H, 4·8. $C_{23}H_{17}O_2Cl$ requires C, 76·6; H, 4·7%).

4-Chloro-ω-methoxy-9-benzylanthracene (XVII; X = OMe).—The ω-bromo-compound (XVIII; 3 g.) was heated on the water-bath for 1½ hours with methyl alcohol (100 c.c.) and calcium carbonate (2 g.). The product, recrystallised from methyl ethyl ketone–alcohol, formed pale yellow crystals, m. p. 144°, fluorescent in solution (Found: C, 79·2; H, 5·2. $C_{22}H_{17}OCl$ requires C, 79·2; H, 5·1%). This *methoxy*-compound was not changed when its solution in methyl alcohol containing hydrochloric or sulphuric acid was submitted to prolonged boiling.

A solution of the methoxy-compound (2·6 g.) in carbon disulphide (15 c.c.) was cooled in a freezing mixture and treated with bromine (0·4 c.c.). The additive compound was not isolated, the carbon disulphide being distilled off and the residue, which had a strong odour of benzaldehyde, treated with a little boiling alcohol. The resulting solid was recrystallised from acetic acid and from methyl ethyl ketone–alcohol and then formed straw-coloured needles; these melted at 152—153°, alone or mixed with the monobromo-derivative of α-chloroanthracene prepared by Barnett and Matthews (*Rec. trav. chim.*, 1924, **43**, 535), so that their compound must have structure (XIX) (Found: Cl + Br, 39·6. Calc.: Cl + Br, 39·6%).

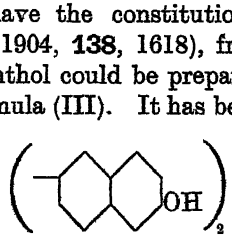
4-Chloro-ω-ethoxy-9-benzylanthracene (XVII; X = OEt).—This was prepared from the bromo-compound (XVIII) by treatment with ethyl alcohol in the presence of calcium carbonate and formed yellowish nodules, m. p. 135—137°, from alcohol (Found: C, 79·5; H, 5·6. $C_{23}H_{19}OCl$ requires C, 79·7; H, 5·5%). This *ethoxy*-compound was fluorescent in solution and was not changed by heating with an alcoholic solution of hydrogen chloride.

THE SIR JOHN CASS TECHNICAL INSTITUTE,
LONDON, E.C. 3. [*Received, August 25th*, 1928.]



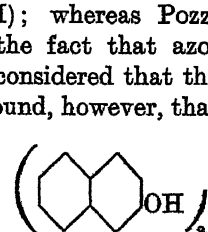
CCCLXXI.—*The Catalytic Production of Polynuclear Compounds. Part I.*

By GEORGE ROGER CLEMO and ROBERT SPENCE.



THE chemistry of certain polynuclear compounds, some of which have assumed considerable commercial importance, *e.g.*, perylene, is but little known, and accordingly a study has been made in the first instance of certain compounds of intermediate complexity. The present communication deals with dinaphthylene oxides. The literature describes two of these compounds, one from α-naphthol (Merz and Weith, *Ber.*, 1881, **14**, 199), and the other obtained by Dianin (*Ber.*, 1875, **8**, 166) by dehydrating β-dinaphthol with phosphoric oxide. Eckstein (*Ber.*, 1905, **38**, 3660) has proved that compounds stated by Knecht and Unzeitig (*Ber.*, 1880, **13**, 1724) and by Walder (*Ber.*, 1882, **15**, 2166) to be isomeric with Dianin's compound are really identical with it. Further, Merz and Weith (*loc. cit.*) and Niederhausern (*Ber.*, 1882, **15**, 1122) claim to have produced from β-naphthol a specially pure form of Dianin's oxide, but it has now been found that, although the yield of this compound thus obtained is less than 5% of the theoretical, it is really isomeric with Dianin's compound (see p. 2812).

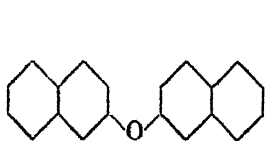
β-Dinaphthol (I) is easily obtained by oxidising β-naphthol with ferric chloride (Dianin, *J. Russ. Phys. Chem. Soc.*, 1874, **6**, 187), and the presence of the 1 : 1′-dinaphthyl linking in it was inferred by Julius (*Ber.*, 1886, **19**, 2549) from the fact that when it was distilled with zinc dust 1 : 1′-dinaphthyl appeared to be formed. Schoepfle, however (*J. Amer. Chem. Soc.*, 1923, **45**, 1566), has shown that a dinaphthylene oxide and not 1 : 1′-dinaphthyl results from this reaction.



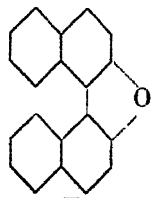
Hodgkinson and Limpach (J., 1891, **59**, 1100) distilled sodium 2-naphthol-6-sulphonate and, obtaining a mixture of β-naphthol, a dinaphthyl ether, and a dinaphthylene oxide, suggested that β-dinaphthol might have the constitution (II); whereas Pozzi Escot (*Compt. rend.*, 1904, **138**, 1618), from the fact that azo-derivatives of β-dinaphthol could be prepared, considered that the compound had the formula (III). It has been found, however, that

(I.)

(II.)

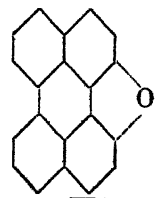


(III.)

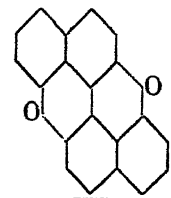


β-dinaphthol, together with a dinaphthylene oxide and a [illegible] thylene dioxide (VII), is formed when 1-bromo-2-naph[illegible]ol is

treated with copper powder, a result which indicates that (I) is its correct formula.



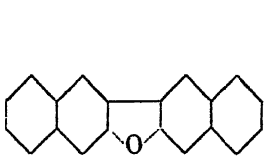
The dinaphthylene dioxide mentioned above has been prepared recently by Pummerer, Prell, and Rieche (*Ber.*, 1926, **59**, 2159) by heating the copper salt of β-dinaphthol at 280°, and in all probability it has the constitution (VII). The oxide produced by the dehydration of β-dinaphthol, therefore, will be 1 : 1′-dinaphthylene 2 : 2′-oxide (V), a conclusion borne out by its conversion into furoperylene (VI) by treatment with aluminium chloride (Weitzenbock, Seer, and von Bartsch, *Ber.*, 1913, **46**, 1994).



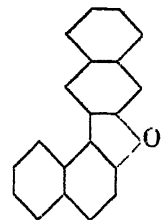
(IV.)

(V.)

(VI.)

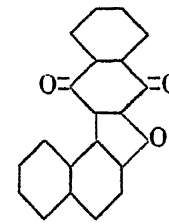


(VII.)



It has now been found that (I) can be converted into (V) by the agency of catalysts such as vanadium pentoxide, and further, that when β-naphthol itself is heated in an open-necked flask at 300° with the trioxide of either tungsten or molybdenum it is converted into the ether (IV); whereas if vanadium pentoxide be used, then, instead of (IV), β-dinaphthol is formed at 300°, and is converted into 1 : 1′-dinaphthylene 2 : 2′-oxide at 340°. If, however, in the latter experiment air is excluded from the flask, by fitting it with a long air condenser, or by the passage of a stream of carbon dioxide, then (IV) only is formed. In the above production of (V) from β-naphthol, therefore, the first reaction is the fairly rapid catalytic air-oxidation to (I), and is followed by catalytic dehydration to (V). All attempts to effect the catalytic air-oxidation of (IV) to (V) have failed. The action of titanium dioxide is intermediate between those of tungsten or molybdenum oxide and vanadium pentoxide, in that it gives a mixture of (IV) and (V) containing a considerable proportion of the former.

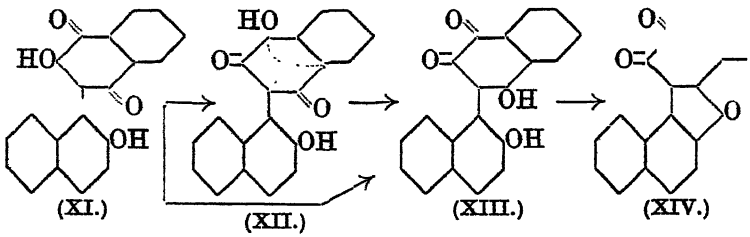
By the action of other catalysts, such as the alkaline-earth oxides, on β-naphthol an oxide isomeric with (V) is easily formed in quantity. This compound, hereinafter called the *iso*oxide, is identical with that obtained in very small yield by Merz and Weith (*loc. cit.*). In this catalytic reaction a second compound, m. p. 300°, is formed, which corresponds to a compound mentioned by Niederhausern (*loc. cit.*), but insufficient has been obtained for investigation. The properties of the *iso*oxide point to its being a structural isomeride of (V) having the constitution (VIII) or (IX), and hence its formation appears to



involve unusual reactivity of hydrogen in the β′-position in a mono-β-substituted naphthalene. The formation of 2-hydroxy-3-naph-

(VIII.)

(IX.)

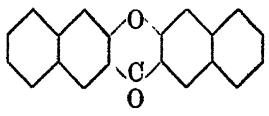


(X.)

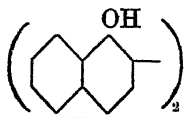
thoic acid from sodium β-naphthoxide is the one well-established case of such β′-reactivity, and indicates that calcium β-naphthoxide also might be reactive in this position.

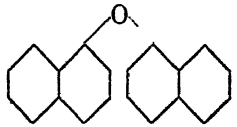
Both (V) and the *iso*oxide are stable to almost red-hot zinc dust and are scarcely acted on by fused potassium hydroxide. Reduction with hydriodic acid gives hydrogenated naphthalenes, and oxidation with sulphuric acid gives phthalic acid, in both cases. Chromic acid oxidation, however, destroys (V) but converts the *iso*oxide into a *quinone*, which does not condense with *o*-phenylenediamine and is therefore presumably of the para-type. Such marked difference in behaviour on oxidation suggests that the *iso*oxide is (IX) and not (VIII), for the latter would be expected to give a diquinone if a quinonoid compound were formed. The quinone is therefore probably (X).

When the quinone is distilled with zinc dust the *iso*oxide is regenerated, and on reduction with zinc and acetic anhydride it gives an O-*diacetyl* derivative which still contains the ether linking. The great stability of the furan ring of the *iso*oxide towards alkalis no longer persists in the quinone, however, for when this is treated with alcoholic sodium hydroxide the ring is easily opened to give a *dihydroxydinaphthaquinone*. This compound undergoes a remarkable change on heating: water is lost, but instead of the original *p*-quinone being regenerated an isomeric compound is produced. This forms red needles and condenses easily with *o*-phenylenediamine to give a substituted *phenazine*. It is therefore presumably an o-*quinone*. This transformation is explicable with formula (IX) for the *iso*oxide but not with (VIII): when the furan ring of the quinone (X) is opened, rotation of the top portion of the molecule seems to occur to give (XI), as evidenced by the formation, on treatment with acetic anhydride, of a yellow O-*diacetyl quinone* derivative. If rotation had not taken place, it would be expected that (X) would be re-formed under these conditions. The reduction of the *o*-quinone (XIV) from (XI), with the loss of water,



seems to necessitate the prior formation of (XIII). If this be granted, the reaction appears to involve one or other of two contentious mechanisms, *viz.*, either the migration of a hydrogen atom from one oxygen atom to another in the meta-position with respect to the first, or the migration of the hydrogen in the first instance to an ortho-oxygen atom with temporary formation of the *m*-quinone (XII), followed by a para-migration to give (XIII).





Whilst the above work was progressing an attempt was made to synthesise the symmetrical 2 : 2′-dinaphthylene 3 : 3′-oxide (VIII). The aim of the first series of experiments was to produce the 2 : 2′-dinaphthyl linking and then to introduce the oxygen bridge. 2-Chloro-3-naphthoic acid was treated with copper powder as in the Ullmann reaction (Ullmann and Bielecki, *Ber.*, 1901, **34**, 2184), but only β-naphthoic acid resulted; when ethyl 2-chloro-3-naphthoate was used, the chlorine atom was found to be stable to copper-bronze in boiling nitrobenzene. A similar treatment of either 3-*bromo*-2-*methoxynaphthalene* or its iodo-analogue gave only β-methoxynaphthalene, and 3-*bromo*-β-*naphthol* gave β-naphthol. These 2 : 3-disubstituted naphthalenes were prepared by applying the Hofmann reaction to 2-methoxy-3-naphthoamide. (Fries, *Ber.*, 1925, **58**, 2845, was unable to apply this reaction to 2-hydroxy-3-naphthoamide, as it gave 1-bromo-2-hydroxy-3-naphthoamide instead of the amino-compound.) The second series of experiments aimed at the prior formation of the oxide linking and the subsequent introduction of the dinaphthyl link. The action of tungsten trioxide and of vanadium pentoxide (see p. 2819) on 2-hydroxy-3-naphthoic acid and its ester was investigated with a view to preparing the dinaphthyl ether dicarboxylic acid. Then the Hofmann reaction on the di-amide, followed by diazotisation of the diamino-ether and treatment with ammoniacal copper sulphate (Carpmael, E.P. 278100, 1926), should give the oxide (VIII). Under all the conditions tried, however, the condensation could not be stopped at the ether stage, but easily gave Strohbach's dinaphthaxanthone (XV) (*Ber.*, 1901, **34**, 4144).

The action of catalysts on α-naphthol has also been investigated. Vanadium pentoxide converts it into the α-dinaphthylene oxide of

Merz and Weith (*loc. cit.*). The constitution of this compound follows from its preparation by the dehydration of α-dinaphthol. There was no direct evidence for the constitution of the latter compound until Willstätter and Schuler (*Ber.*, 1928, **61**, 362) showed that it is in all probability 1 : 1′-dihydroxy-2 : 2′-dinaphthyl (XVI).

(XV.)

(XVI.)

(XVII.)

Hence α-dinaphthylene oxide would appear to have the constitution (XVII). The same oxide results when α-naphthol is treated with calcium oxide, since, failing a Kaufler type of oxide as the result of a 4 : 4′-dinaphthyl linking, α-naphthol would be expected to form only one dinaphthylene oxide.

Experimental.

β-*Dinaphthol* (I).—1-Bromo-2-naphthol (22 g.), copper bronze (7·5 g.), and iodine (0·5 g.) were heated for 3 hours at 280°. The product was extracted with alkali, the filtered solution acidified with hydrochloric acid, and the precipitate collected and freed from β-naphthol by extraction with boiling water. The residue, crystallised from aqueous alcohol and from glacial acetic acid, gave needles, m. p. 216°, not depressed by admixture with a specimen of β-dinaphthol made by oxidising β-naphthol with ferric chloride (Found: C, 83·5; H, 5·1. Calc. for $C_{20}H_{14}O_2$: C, 83·9; H, 4·9%). From the alkali-insoluble material, boiling acetic acid extracted 1 : 1′-dinaphthylene 2 : 2′-oxide, which separated, on cooling, in needles, m. p. 156° (see below). The residue was crystallised from toluene and gave yellow needles (0·5 g.) of 1 : 1′-dinaphthylene 2 : 8′ : 2′ : 8-dioxide (VII), m. p. 236° (Found: C, 84·5; H, 3·5. Calc. for $C_{20}H_{10}O_2$: C, 85·1; H, 3·5%).

Catalytic Dehydration of β-*Dinaphthol.* 1 : 1′-*Dinaphthylene* 2 : 2′-*Oxide* (V).—β-Dinaphthol (25 g.) and vanadium pentoxide (1 g.) were gently boiled in a round-bottomed flask for 7 hours. When the product, which contained no alkali-soluble material, was vacuum-distilled, only almost pure 1 : 1′-dinaphthylene 2 : 2′-oxide (12 g.) passed over. This crystallised from benzene in pale yellow needles, m. p. 156° (Found: C, 89·5; H, 4·8. Calc. for $C_{20}H_{12}O$: C, 89·6; H, 4·5%). The oxide gives a purple colour in concentrated sulphuric acid, changing to red and then to dark brown on warming. The picrate has m. p. 164°.

Action of Catalysts on β-*Naphthol.*—(a) *Di*-β-*naphthyl ether* (IV). β-Naphthol (20 g.) and tungsten trioxide (0·5 g.) were heated in a

round-bottomed, long-necked flask (250 c.c.), first at 270° and then slowly to 300° as the β-naphthol reacted. After heating for 2 hours, the melt was poured into an excess of boiling caustic soda solution. On cooling, the solid residue was collected (recovered β-naphthol, 3·3 g.), dried (14 g.), and vacuum-distilled. The total distillate (12·5 g.) was crystallised from ligroin and gave colourless plates, m. p. 105°.

(b) *β-Dinaphthol.* β-Naphthol (20 g.) and vanadium pentoxide (0·5 g.) were heated as in (a), for 5 hours, at 300°. The product was extracted with boiling sodium hydroxide solution, in which it was almost completely soluble, and the hot filtered solution was treated with excess of hydrochloric acid. After cooling, the precipitate was collected and extracted with boiling water to remove unchanged β-naphthol. The residual β-dinaphthol (8 g.), after crystallising from glacial acetic acid, had m. p. 216°.

(c) *1 : 1′-Dinaphthylene 2 : 2′-oxide* (V). β-Naphthol (100 g.) and vanadium pentoxide (1 g.) were heated in a flask for 5 hours, the temperature rising slowly from 270° to 340°. The product was extracted with alkali, and β-naphthol (4 g.) and crude β-dinaphthol (13 g.) were obtained from the extract. The dark alkali-insoluble residue was dried (50 g.) and distilled, giving 43 g. of a pale yellow solid which, when crystallised from benzene–alcohol to free it from a little di-β-naphthyl ether, gave 1 : 1′-dinaphthylene 2 : 2′-oxide (30 g.), m. p. 156°.

(d) iso*Dinaphthylene oxide* (IX). β-Naphthol (100 g.) and calcium oxide (1 g.) were heated as in (c) for 10 hours, the temperature being raised slowly from 270° to 340°. The product was treated with alkali to free it from unchanged β-naphthol, and the residue distilled. The distillate, a colourless solid (44 g.), was extracted with benzene (300 c.c.), leaving 0·5 g. of the solid of m. p. 300° (see p. 2812). Alcohol (300 c.c.) was added to the extract; the colourless plates of the iso*oxide* (30 g.) thus obtained, after recrystallisation from glacial acetic acid, melted at 158—159°; mixed m. p. with (V), 130—140° (Found: C, 89·3; H, 4·4. $C_{20}H_{12}O$ requires C, 89·6; H, 4·5%). The compound is easily soluble in benzene, less soluble in alcohol, and gives in sulphuric acid an orange-red solution, which changes through scarlet, purple, and blue to light brown on warming.

Dibromoisodinaphthylene Oxide.—When the *iso*oxide (3·6 g.), dissolved in carbon disulphide, was slowly treated with bromine (2·5 c.c.), colourless needles of the *dibromo*-compound separated (5·9 g.), which, after recrystallisation from benzene and from acetic acid, had m. p. 193° (Found: Br, 37·4. $C_{20}H_{10}OBr_2$ requires Br, 37·6%).

Oxidation of 1 : 1′-Dinaphthylene 2 : 2′-Oxide (V) *and of the* iso-

Oxide.—(a) *With sulphuric acid.* Concentrated sulphuric acid (50 c.c.) and either of the above two oxides (7 g.), with a little mercury and copper sulphate as catalyst, were heated together. On distillation, phthalic acid (1·3 g.) (anhydride, m. p. 128°) passed over.

(b) *With chromic acid.* iso*Dinaphthaquinone oxide* (X). The *iso*oxide (10 g.) was refluxed for 10 minutes with 250 c.c. of a chromic acid mixture (made by dissolving potassium dichromate, 60 g., in concentrated sulphuric acid, 80 g., and water, 270 c.c.), water was then added, and the solid collected. It was crystallised first from acetic acid (solubility, 0·5%) and then from pyridine, bronze leaflets (4·5 g.) being obtained, m. p. 268° (Found: C, 80·2; H, 3·5. $C_{20}H_{10}O_3$ requires C, 80·5; H, 3·4%). The *quinone* sublimes unchanged, and gives in sulphuric acid a bluish-green solution which becomes brown on heating.

After 1 : 1′-dinaphthylene 2 : 2′-oxide has been treated with chromic acid as above, no solid is obtained on dilution with water.

Reduction of the Quinone (X). *Diacetoxyisodinaphthylene Oxide.*—The quinone (5 g.) and acetic anhydride (20 c.c.) were refluxed for 15 minutes in presence of zinc dust (5 g.). The liquid was filtered and poured into water with rapid stirring. The colourless solid obtained crystallised from acetic acid in needles (5 g.), m. p. 245—246° (Found: C, 75·0; H, 4·0. $C_{24}H_{16}O_5$ requires C, 75·0; H, 4·2%).

Hydrolysis of the Quinone.—The quinone (4 g.) was refluxed with alcoholic sodium hydroxide (1 l. of 0·5% solution) for 10 hours and the solution was then concentrated to small bulk, diluted with water, and filtered. The filtrate, treated with an excess of hydrochloric acid, gave a reddish-brown precipitate, which was washed with water and dried in a vacuum desiccator (3·8 g.). It crystallised from chloroform in light red prisms with solvent of crystallisation, which was driven off by heating on the water-bath; m. p. 222° (Found: C, 76·0; H, 3·5. $C_{20}H_{12}O_4$ requires C, 75·9; H, 3·8%). *Dihydroxydinaphthaquinone* crystallises from benzene in needles, with benzene of crystallisation, and from acetic acid in rhombohedra.

Diacetoxydinaphthaquinone.—Dihydroxydinaphthaquinone (0·5 g.) was refluxed with acetic anhydride (20 c.c.) and a drop of pyridine for 10 minutes, and the mixture poured into water. The precipitate obtained was crystallised first from glacial acetic acid and then twice from alcohol, giving golden-yellow needles, m. p. 167° (Found: C, 71·7; H, 4·3. $C_{24}H_{16}O_6$ requires C, 72·0; H, 4·0%). This *diacetyl* compound gives a reddish-brown colour with concentrated sulphuric acid, and dissolves in hot potassium hydroxide solution with a red colour, the original dihydroxydinaphthaquinone being precipitated by the addition of hydrochloric acid.

o-*Dinaphthaquinone Oxide* (XIV).—The dihydroxy-quinone (2 g.)

was heated at 250°, and after about 5 minutes evolution of steam ceased. The product crystallised from benzene in deep red needles (1·1 g.), m. p. 255—256° (Found: C, 80·7; H, 3·4. $C_{20}H_{10}O_3$ requires C, 80·5; H, 3·4%). The *o-quinone oxide* gives with sulphuric acid a brown colour which turns green on warming.

Condensation to a phenazine. The *o*-quinone oxide (0·3 g.) and *o*-phenylenediamine (0·2 g.) were refluxed in acetic acid (60 c.c.) for ½ hour. After cooling, the solid was collected; it crystallised from glacial acetic acid in yellow needles (0·25 g.), m. p. 240° (Found: N, 7·3. $C_{26}H_{14}ON_2$ requires N, 7·6%).

Action of Copper-bronze on 2-Chloro-3-naphthoic Acid.—2-Chloro-3-naphthoic acid (10 g.) was dissolved in nitrobenzene (50 c.c.), copper-bronze (25 g.) added, and the mixture refluxed for 2 hours. A solution of sodium hydroxide was then added, the nitrobenzene removed in steam, and the residual alkaline solution filtered and acidified. The resulting precipitate crystallised from acetone in needles (4 g.), m. p. 185°, and gave an amide, m. p. 197°, and was therefore β-naphthoic acid.

2-Methoxy-3-naphthoic Acid.—2-Hydroxy-3-naphthoic acid (10 g.), treated with methyl sulphate and sodium hydroxide, gave 11 g. of 2-methoxy-3-naphthoic acid. This was converted into the amide, m. p. 170° after crystallising from acetone.

2-Methoxy-3-naphthylamine.—Chlorine, from potassium permanganate (5·3 g.), was passed into an ice-cooled solution of sodium hydroxide (14 g.) in water (100 c.c.). The resulting hypochlorite was added to the finely powdered amide (15 g.) and warmed in a water-bath with stirring, the temperature being kept below 70° until the reaction had subsided. Sodium hydroxide solution was then added, the mixture heated on a water-bath for an hour, the amine extracted with benzene, the benzene removed, and the residue distilled under reduced pressure. The distillate crystallised from methyl alcohol in colourless plates (5 g.), m. p. 109·5° (Found: C, 76·1; H, 6·6; N, 8·4. $C_{11}H_{11}ON$ requires C, 76·3; H, 6·4; N, 8·1%). The *amine* forms an *acetyl* derivative which crystallises from methyl alcohol in colourless plates, m. p. 124—125° (Found: C, 73·0; H, 6·2. $C_{13}H_{13}O_2N$ requires C, 72·6; H, 6·1%).

3-Bromo-2-methoxynaphthalene.—2-Methoxy-3-naphthylamine (17 g.), in a mixture of concentrated hydrochloric acid (20 c.c.) and water (150 c.c.), was diazotised with sodium nitrite (7 g.). A solution of cuprous bromide (prepared from copper sulphate, 20 g.) in hydrobromic acid (30 c.c.; *d* 1·44) was cooled in ice, and the diazo-solution added. After ½ hour, the mixture was warmed on the water-bath until no more nitrogen was evolved; the product was then extracted with benzene, and the extract fractionated. The

fraction of b. p. 178—190°/16 mm. (6·5 g.) was crystallised from methyl alcohol and then from ligroin (b. p. 40—60°), giving colourless plates, m. p. 76° (Found: Br, 33·2. $C_{11}H_9OBr$ requires Br, 33·75%).

3-Iodo-2-methoxynaphthalene.—2-Methoxy-3-naphthylamine (5 g.) was diazotised as above, and an aqueous solution of potassium iodide (5 g.) added. The solution was stirred for ½ hour, heated to boiling, made alkaline, and extracted with benzene. The benzene was removed, and the residue vacuum-distilled, giving a pale yellow oil which solidified; it crystallised from methyl alcohol in colourless prisms, m. p. 65° (Found: I, 44·2. $C_{11}H_9OI$ requires I, 44·7%).

3-Bromo-β-naphthol. — 3-Bromo-2-methoxynaphthalene (4·5 g.) was refluxed with hydrobromic acid (50 c.c.; *d* 1·44) for 4 hours, and the mixture was then diluted with water and cooled, and the solid collected. This was extracted with sodium hydroxide, the filtered solution acidified, and *3-bromo-β-naphthol* dried and distilled (2 g.). It crystallised from ligroin (b. p. 40—60°) in well-defined needles, m. p. 80—81°; mixed m. p. with 1-bromo-β-naphthol (m. p. 84°), 45—55°. As the bromine determinations were always about 1% low, the product probably contained a small amount of β-naphthol (Found: Br, 34·7. $C_{10}H_7OBr$ requires Br, 35·9%).

The use of hydriodic acid instead of hydrobromic acid for demethylation resulted in both 3-bromo- and 3-iodo-2-methoxynaphthalene being reduced to β-naphthol.

Dinaphthaxanthone.—2-Hydroxy-3-naphthoic acid (6 g.) and tungsten trioxide (0·05 g.) or vanadium pentoxide were heated together for ½ hour, the residue was extracted with alkali, and the insoluble portion was dried and distilled under reduced pressure. The distillate (2 g.) crystallised from glacial acetic acid in long, yellow needles, m. p. 134—135° (Found: C, 85·3; H, 4·1. Calc. for $C_{21}H_{12}O_2$: C, 85·1; H, 4·1%). Ethyl 2-hydroxy-3-naphthoate gave the same result.

2 : 2′-Dinaphthylene 1 : 1′-Oxide (XVII).—α-Naphthol (20 g.) was heated with vanadium pentoxide (1 g.) for 4 hours, the temperature rising to 340°. The product was extracted with alkali, and the insoluble portion distilled. The distillate crystallised from benzene–alcohol in yellow needles, m. p. 179° (Found: C, 89·2; H, 4·6. Calc. for $C_{20}H_{12}O$: C, 89·6; H, 4·5%).

One of the authors (R. S.) wishes to thank the Department of Scientific and Industrial Research for a grant which has enabled him to take part in this investigation.

UNIVERSITY OF DURHAM, ARMSTRONG COLLEGE,
NEWCASTLE-UPON-TYNE. [*Received, August 2nd,* 19[illegible]

CCCLXXII.—*The Crystal Structure of Silver Subfluoride.*

By HENRY TERREY and HUGH DIAMOND.

THE peculiar valency relationships existing in sub-compounds make it desirable to establish conclusively the existence of these substances as definite chemical individuals, and for this purpose *X*-ray methods appear to yield the most promising results (compare Levi, *Gazzetta*, 1924, **54**, 598). Silver subfluoride, Ag_2F, one of the most interesting and well-defined of these compounds, was chosen for investigation in this manner, but a specimen of the substance prepared by Wöhler's method (*Z. anorg. Chem.*, 1912, **78**, 242) yielded unsatisfactory *X*-ray photographs in which the presence of silver lines indicated the heterogeneity of the sample. However, since the commencement of this work, Hettich (*ibid.*, 1927, **167**, 70) has prepared large crystals of silver subfluoride electrolytically and demonstrated its chemical entity by an *X*-ray comparison of his product with silver and with the normal fluoride. Hettich's method of preparation was therefore adopted by us, and our main object was then confined to the elucidation of the crystal structure of silver subfluoride as revealed by its *X*-ray diffraction pattern.

Silver subfluoride crystals, prepared by electrolysing a concentrated solution of silver fluoride at 60° with a low current density, were washed with alcohol and ether and dried in a vacuum (Found : total Ag, 91·5; soluble Ag, 45·1; F, 8·0. Calc. : total Ag, 91·9; soluble Ag, 45·95; F, 8·1%).

A comparison photograph of silver subfluoride and sodium chloride was obtained by the powder method of Debye–Scherrer and Hull, a Shearer tube fitted with a copper anticathode being used as a source of *X*-radiation. The results of measurements made upon this photograph are given in Table I, the calculated values of d_{hkl}/n being based on a hexagonal lattice of side 2·989 Å.U. and height 5·710 Å.U., which was deduced from the observed values of the interplanar spacings by means of Hull's plots (*Physical Rev.*, 1921, **17**, 549). One molecule of Ag_2F in a cell of these dimensions requires a density of 8·78, whereas the experimentally determined value is 8·64 (Hettich gives 8·57).

In Table II are recorded measurements made upon a plain silver subfluoride photograph, and the strong lines have been employed for calibration purposes, data from Table I being used. In this way it has been possible to identify the weak lines and thus obtain useful information for intensity considerations.

Silver subfluoride is a hard, metallic-looking substance, not easily reduced to powder in a mortar. It seems probable, therefore, that the atoms of silver and fluorine are closely packed, and the compound would appear to have a " cadmium iodide " structure.

This is shown in Fig. 1, in which the large circles denote silver atoms and the small circles fluorine atoms. Fluorine occupies the position (0, 0, 0) and silver the positions $(\frac{1}{3}, \frac{2}{3}, \mu)$ and $(\frac{2}{3}, \frac{1}{3}, \bar{\mu})$. The value of the parameter μ, the distance between successive planes of silver and fluorine atoms, may be deduced from intensity considerations, and for this purpose the relations between the intensities of the various orders of reflexion from the 0001 plane are valuable. It has been possible to obtain crystals with well-developed faces parallel to the 0001 plane and also to the 1011 plane, and to record the various orders of reflexion from them. The observed intensities of the first-, second-, and third-order reflexions from the 0001 plane do not exhibit a normal decline : the second order is stronger than the first, and the third order is stronger than the first but weaker than the second. A weak fifth-order reflexion also occurs. In the case of the 1011 plane only a first-order reflexion is obtained. In Table III an estimated value of the intensity of reflexion is given for each line observed, and intensities calculated for several values of μ are also given for comparison. The lines have been divided into groups in which each is derived from the same type of plane. Some of the lines are unresolved doublets, and in these cases it has been impossible to assign any definite observed intensity values to the components. The indices of co-operating planes have therefore been inserted after the observed intensity value.

FIG. 1.

The expression $I = NS^2/\sin^2\theta$, where N is the number of co-operating planes and $S = 10 + 46[e^{i2\pi n(h/3+2k/3+\mu l)} + e^{i2\pi n(2h/3+k/3+\bar{\mu}l)}]$, has been used in the above calculations.

The most satisfactory agreement between observed and calculated values occurs when $\mu = 0{\cdot}3$. There is, however, an obvious discrepancy in the case of the 1120 plane, but this could not be eliminated by a change of μ. Apart from this inconsistency, the general similarity of observed and calculated intensities in each

TABLE III.

group is good, and it is suggested that a "cadmium iodide" structure, with μ = app. 0·3, is fairly representative of silver subfluoride.

When $\mu = 0{\cdot}3$, the atomic diameter of silver with respect to silver is about 2·8 Å.U. and with respect to fluorine about 3·6 Å.U., and it is significant that these values are equal to the atomic diameters of silver in the metallic state and in normal combination, respectively. This seems to indicate that the relation between adjacent silver atoms resembles that existing in the metallic state, and that the relation between adjacent silver and fluorine atoms is similar to that in normal silver fluoride. Perhaps in the formation of a molecule of subfluoride two silver atoms partly share their uncompleted rings of electrons, leaving between them in reserve an electron to complete the electron ring of a fluorine atom. If this be the case, previous hypotheses postulating the existence of "sub-ions" would appear to have some justification, and the metallic properties of silver subfluoride (*e.g.*, electrical conductivity of the order of that of graphite) would find a ready explanation.

Summary.

Silver subfluoride has been examined by the powder method, and found to possess a hexagonal unit cell of dimensions $a = 2{\cdot}989$ Å.U. and $c = 5{\cdot}710$ Å.U. The density corresponds to one molecule in the unit cell. Intensity considerations appear to agree with a

" cadmium iodide " structure with the parameter μ equal to about 0·3.

In conclusion, one of us (H. D.) wishes to express his grateful thanks to the Salters' Institute for a grant which has enabled him to take part in this research.

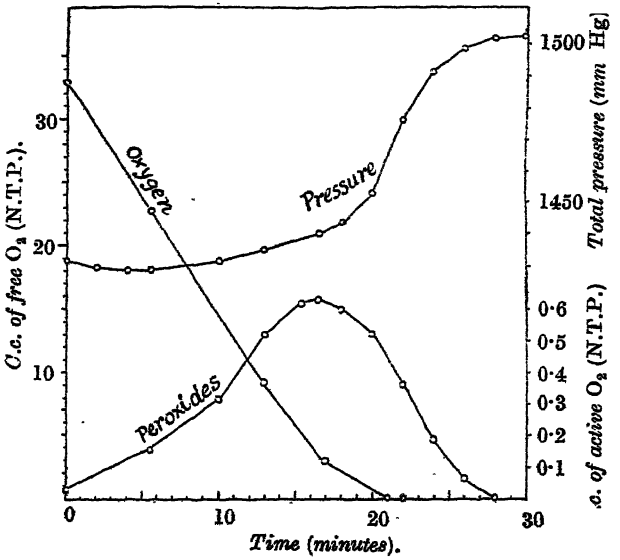
UNIVERSITY COLLEGE, LONDON. [*Received, June 29th*, 1928.]

NOTES.



The Oxidation of n-*Hexane.* By MAX BRUNNER and ERIC KEIGHTLEY RIDEAL.

IN a previous communication (this vol., p. 1162), it was shown that *n*-hexane–air mixtures in a closed bulb maintained at temperatures well below the so-called critical inflexion temperature or temperature of initial combustion actually underwent reaction at appreciable velocities. The pressure–time curves all exhibited well-marked characteristics, a period of no or small pressure change followed by a short and final period of rapidly rising pressure. It was assumed that these two periods were characterised in their rates of reaction, it being thought that the " induction " period was a period of slow combustion, which was followed by a period of rapid combustion, this being initiated by a rising content of peroxide molecules. Further investigation on the rate of oxygen consumption, whilst confirming the view that the period of rapid pressure increase is associated with an oxidation process by means of peroxide molecules formed prior to the observed pressure increase, has shown that the rate of oxygen uptake during the initial period of no pressure change, previously called the induction period, is in reality quite rapid. This is made clear from a consideration of the curves representing the analyses, conducted as previously described, after various periods of time of a 42% (by volume) hexane–58% oxygen mixture maintained in a bulb of 57·9 c.c. capacity at 210°. It is evident that the rapid increase in pressure occurs when the oxygen has almost disappeared and is to be attributed to reactions involving decomposition or reaction of peroxide molecules. It is significant that the rate of oxygen uptake appears to be a zero-order reaction over a wide range of pressure.

The results of a detailed examination of the varied compositions of the reaction products during this period of isopiestic combustion have been described by one of us (M. B., *Helv. Chim. Acta*, Oct.,

1928), but it is clear that observations on the rate of change of pressure or volume or on the content of substances giving peroxide reactions, two methods frequently adopted, are not safe criteria for determination of reaction velocities in the slow combustion of hydrocarbons. The reactions which appear to predominate in the

FIG. 1.

initial stages of combustion in glass vessels at low temperatures may be summarised by the equations

$$C_6H_{14} + O_2 \longrightarrow C_6H_{14}O_2 \text{ (active moloxide)}$$
$$C_6H_{14} \cdot C_6H_{14}O_2 \longrightarrow 2C_6H_{12} + 2H_2O$$
$$C_6H_{12} + O_2 \longrightarrow C_6H_{12}O_2 \longrightarrow \text{decomposition.}$$

Although, at low temperatures, surfaces appear to play an important part in the formation of peroxides, consideration of the great reaction velocity during the period of no pressure change leads us to suspect that the peroxides themselves cannot be the reaction centres for the propagation of the chemical action through the homogeneous bulk phase.—THE UNIVERSITIES OF ZÜRICH AND CAMBRIDGE.

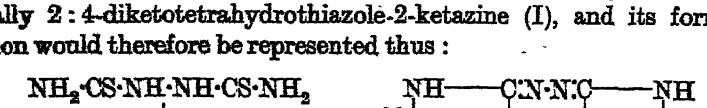
The Preparation of Cholestenone. By WILFRED ARCHIBALD SEXTON.

A MIXTURE of pure cholesterol (20 g.) and copper bronze (15 g.) was heated gently at 2—3 mm. pressure in a 200 c.c. Jena glass distillation flask (see Heilbron and Sexton, this vol., p. 347). As soon as

the sterol was molten a violent reaction commenced with evolution of a thick white vapour. This condensed as a white powder in a second distillation flask serving as receiver; glass wool in a U-tube placed between the side arm and the pump effectually prevented the escape of solid particles. After a few minutes the violence of the reaction abated and the catalyst became caked together in a porous mass. The sublimate (0·2 g.) proved to be unchanged cholesterol. The temperature was then gradually raised until distillation commenced. The distillate (280—290°/3—4 mm.) (17 g.) was golden-yellow and of high viscosity. It crystallised from methyl alcohol at 0° in white needles (6 g.), m. p. 72—76°, which was raised to 80° by repeated crystallisation from methyl alcohol: no depression of m. p. occurred on heating a mixture with cholestenone prepared by heating the sterol with copper oxide. It gave the characteristic semicarbazone, m. p. 234°. By evaporation of the filtrate in a desiccator over calcium chloride a further crop (10 g.) of crude cholestenone was obtained (total yield, 80%).—THE UNIVERSITY, LIVERPOOL. [*Received, August 25th*, 1928.]



The so-called Bisthiohydantoins of Frerichs, Förster, and Höller.

By HERBERT WILLIAM STEPHEN and FORSYTH JAMES WILSON.

BY the interaction of hydrazodithiodicarbonamide and chloroacetic acid in boiling aqueous solution, Frerichs and Förster (*Annalen*, 1909, **371**, 257) obtained a compound which they regarded as 3 : 3-bisthiohydantoin (or, according to present nomenclature, 3 : 3-bis-ψ-thiohydantoin); and in a similar manner, from α-bromopropionic and -*n*-butyric acids Frerichs and Höller (*ibid.*, 1913, **398**, 256) obtained compounds considered to be substituted 3 : 3-bis-ψ-thiohydantoins (R = Me or Et):

$$NH_2\cdot CS\cdot NH\cdot NH\cdot CS\cdot NH_2 + 2CHRBr\cdot CO_2H = \begin{array}{l} NH{:}C\text{———}N\text{—}N\text{———}C{:}NH \\ \quad\ S\cdot CHR\cdot CO\ \ CO\cdot CHR\cdot S \end{array} + 2H_2O + 2HBr.$$

In a recent communication (this vol., p. 1415) we showed from the products of hydrolysis that the so-called 3 : 3-bis-ψ-thiohydantoin is really 2 : 4-diketotetrahydrothiazole-2-ketazine (I), and its formation would therefore be represented thus:

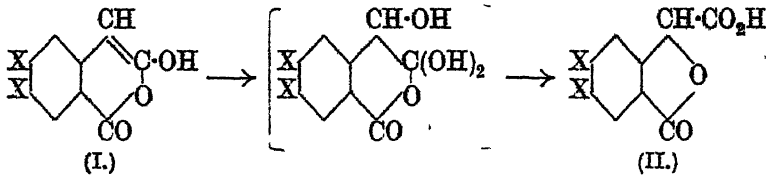
(I).

We have now shown that the two compounds described by Frerichs and Höller give on hydrolysis hydrazine hydrochloride together with the corresponding 5-alkyl derivative of 2 : 4-diketo-

tetrahydrothiazole; and we therefore regard these compounds as 2 : 4-diketo-5-alkyltetrahydrothiazole-2-ketazines.

Frerichs and Höller, in noting that the alleged 3 : 3-bis-ψ-thiohydantoins are more acidic than basic, remark that this is somewhat surprising, since ψ-thiohydantoin is more basic than acidic; but the acidity of these compounds is to be expected from the structures now assigned, since the 2 : 4-diketotetrahydrothiazoles are acidic.

2 : 4-*Diketo-5-methyltetrahydrothiazole-2-ketazine*, prepared by the method of Frerichs and Höller from hydrazodithiodicarbonamide and α-bromopropionic acid, melted sharply at 289° and possessed the properties ascribed to it by these authors, who give the m. p. as above 280°. It was boiled for ½ hour with concentrated hydrochloric acid, and the solution evaporated on the water-bath and finally in a vacuum over soda-lime and concentrated sulphuric acid. Extraction with hot benzene left a residue of hydrazine hydrochloride (identified by conversion into benzalazine), and the extract on evaporation left a viscous oil which solidified after distillation (166—168°/20 mm.); the solid was crystallised from benzene–light petroleum and then had m. p. 46—47°. From its properties this was evidently 2 : 4-diketo-5-methyltetrahydrothiazole (Wheeler and Barnes, *Amer. Chem. J.*, 1900, **24**, 60; Wilson and Burns, J., 1923, **123**, 799).



2 : 4-*Diketo-5-ethyltetrahydrothiazole-2-ketazine*, similarly prepared from α-bromo-*n*-butyric acid, crystallised from glacial acetic acid in slightly rose-coloured plates and, when freed from solvent of crystallisation by washing with ether, had m. p. 233° (Frerichs and Förster give 225—226°) (Found: N, 19·6. Calc.: N, 19·6%). Hydrolysis as in the preceding case yielded hydrazine hydrochloride, and evaporation of the benzene extract left a colourless oil which solidified on cooling; crystallisation of the solid from benzene–light petroleum gave prisms, m. p. 64—65°, identical with 2 : 4-diketo-5-ethyltetrahydrothiazole (Wheeler and Barnes; Wilson and Burns, *locc. cit.*).

We wish to thank the Governors of this College for a Research Assistantship awarded to one of us (H. W. S.).—The Royal Technical College, Glasgow. [*Received, July 26th*, 1928.]

The Enolisation of Homophthalic Anhydrides. By Thomas Stevens Stevens and James Leggat Wilson.

4 : 5-*Methylenedioxyhomophthalic anhydride* (enolic form as [illegible] XX = CH_2O_2) not only resembles the unsubstituted homophthalic anhydride in forming yellow alkali salts (compare Dieckmann,

Ber., 1914, **47**, 1428), but is itself deep yellow in the solid state, unlike homophthalic anhydride on the one hand and methylenedioxyhomophthalic acid on the other. A general investigation of the behaviour of analogous substances was planned, but as a paper bearing on this subject has recently appeared (Davies and Poole, this vol., p. 1616), it was deemed advisable to publish the results so far obtained.

4 : 5-Methylenedioxyhomophthalic anhydride is obtained by boiling the parent acid with excess of acetyl chloride for several hours, until the original white powder has been replaced by yellow crystals. It separates from benzene in yellow needles, m. p. 178—180° [Found : equiv. in ice-cold acetone, 199·8; in boiling water, 102·1. $C_{10}H_6O_5$ requires equiv. 206 (monobasic), 103 (dibasic)]. The anhydride is not readily affected by bromine, but gives a dark brown precipitate with ferric chloride under the conditions specified by Davies and Poole (*loc. cit.*) for homophthalic anhydride.

Preliminary experiments on the methylation of homophthalic anhydride led to no definite result. An estimation by Hieber's method (*Ber.*, 1921, **54**, 902) indicated a small percentage of enol, but no great reliance is to be placed on the observation, as the formation of a stable chelate ring-system (on which the whole method presumably depends) is improbable in the present case. On the other hand, Dieckmann's general criticism (*Ber.*, 1921, **54**, 2251) of the Hieber reaction may not apply here, as the anhydride is a well-defined acid.

When the calculated amount of aqueous permanganate was added to an ice-cold alkaline solution of homophthalic anhydride, phthalidecarboxylic acid (II, X = H), m. p. 151°, was produced, which gave phthalide, m. p. 73°, on heating. Methylenedioxyhomophthalic anhydride similarly yielded methylenedioxyphthalidecarboxylic acid, m. p. 213—215° (decomp.) (Ruhemann, J., 1912, **101**, 783, gives 216° decomp.), and methylenedioxyphthalide, m. p. and mixed m. p. 188—189° (Stevens and Robertson, J., 1927, 2790).—The University, Glasgow. [*Received*, *September* 21*st*, 1928.]

Preparation of 4-Bromophthalic Acid. By LESLIE CHARLES BAKER. PHTHALIC anhydride was converted into ethyl 4-nitrophthalate by Miller's method (*Annalen*, 1881, **208**, 224; compare also Cohen, Woodroffe, and Anderson, J., 1916, **109**, 226), and this compound reduced to the amino-ester by Baeyer's method (*Ber.*, 1877, **10**, 1079). (This reduction is best effected at 30—40°, since at lower temperatures the ester tends to solidify when liberated from its alcoholic solution by the addition of acid.) From the precipitate obtained by neutralising the solution with sodium carbonate, after drying, hot absolute alcohol extracted ethyl 4-aminophthalate in 71% yield. This ester (12 g.) was diazotised at 0° (concentrated hydrochloric acid 36 c.c., water 95 c.c.; sodium nitrite 8 g.), and the resulting mixture poured into an ice-cold solution of cuprous bromide (8 g.) in hydrobromic acid (20 c.c.); after ½ hour, the whole was boiled. An ethereal extract of the cold solution, after being washed with dilute acid, sodium carbonate, and water and dried, yielded 10 g. of ethyl 4-bromophthalate (66%) as a pale yellow oil, b. p. 194—195°/16 mm. Von Braun (*Ber.*, 1923, **56**, 2332) gives the b. p. as 190—191°/16 mm.

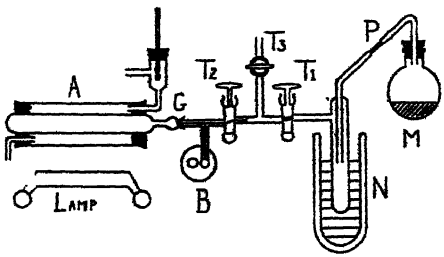
A mixture of ethyl 4-bromophthalate (7 g.) and baryta (9 g.) in water (140 c.c.) and alcohol (100 c.c.) was heated for 2—3 hours with shaking, the solution was then acidified with concentrated hydrochloric acid, and the alcohol boiled off. Hot *N*-sulphuric acid (65 c.c.) was added slowly with stirring, the precipitated barium sulphate removed when cold, and the filtrate concentrated; 4-bromophthalic acid (5 g.; 88% yield) then separated, m. p. 173—175° after recrystallisation from water.—UNIVERSITY COLLEGE, LONDON. [*Received, October 1st*, 1928.]

CCCLXXIII.—*The Photochemical Decomposition of Glyoxal.*

By RONALD G. W. NORRISH and JOHN G. A. GRIFFITHS.

GLYOXAL in its monomeric form is a volatile yellow liquid (b. p. 50°) and constitutes the simplest of organic coloured compounds. It has been found possible to keep the dry gas in a tube for several hours without rapid polymerisation. Its photochemistry does not appear to have been studied, although its absorption spectrum in the gaseous state has been measured by Purvis and McCleland (J., 1912, **101**, 1810) and by Luthy (*Z. physikal. Chem.*, 1923, **107**, 302). The last author found a very large number of [illegible] absorption bands stretching from the blue at 4548 Å.U. to the [illegible]

violet at *ca.* 3000 Å.U., but measurement of fine structure became difficult after λ 3400 Å.U. on account of the weakness of absorption. The results of Purvis and McCleland are in general agreement with these observations. The strongest absorption occurs in the blue–violet region for a group of bands lying between 4554 and 4123 Å.U., those lying beyond this region being much weaker and only measurable at higher pressures.



It was therefore considered of interest to investigate the photochemistry of glyoxal vapour, especially as the results might eventually be expected to be of importance biochemically, as, for instance, in connexion with the problem of photosynthesis.

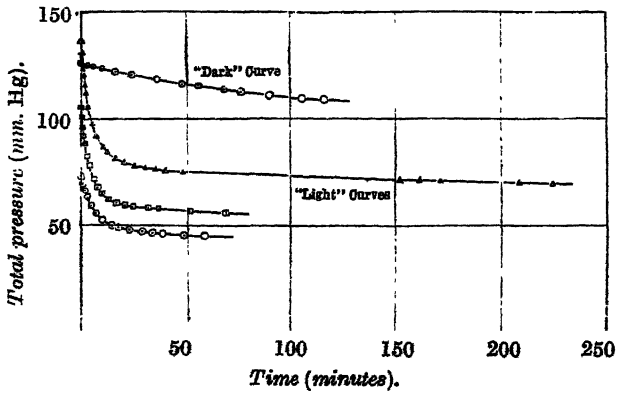
Experimental.

(A) *The Photochemical Decomposition.*

The photochemical experiments were carried out in the all-glass apparatus shown in Fig. 1. The monomeric glyoxal was prepared as required by heating a mixture of solid (polymeric) glyoxal and phosphoric oxide in the bulb *M*, after the method of Harries and Temme (*Ber.*, 1907, **40**, 165). The reaction gives rise to a mixture of carbon monoxide, carbon dioxide, and glyoxal vapour, and the last two were separated from the first by condensation in the liquid-air trap, *N*. When sufficient glyoxal had been prepared, the preparation bulb was sealed off at *P*, and the carbon monoxide pumped away from the trap by a Toepler pump *via* tap T_3. The trap was next surrounded by a freezing mixture of ice and hydrochloric acid at $-25°$, a temperature at which practically all the glyoxal was retained whilst the carbon dioxide could be pumped away. The glyoxal was stored in the trap surrounded by liquid air, and could be kept thus for at least a day without much polymerisation.

Fig. 1.

The reaction chamber consisted of a glass, water-jacketed vessel, *A*, of 75 c.c. capacity, connected with the rest of the apparatus by the ground-glass joint, *G*, and kept at 25° by means of water pumped from an electrically regulated thermostat.



After complete evacuation of the apparatus, the glyoxal in the trap was allowed to attain room temperature, and the reaction chamber was filled to the desired pressure *via* taps T_1 and T_2,

pressures being measured on the mercury manometer, *B*. The vapour was then exposed to the action of light, and readings of the manometer were taken at short intervals of time.

In a preliminary experiment the unfiltered light from a 1000-c. p. filament lamp was used. The pressure in the reaction vessel decreased rapidly at first, and this rate of decrease diminished progressively with time.

The unfiltered light from a 3000-c. p. mercury-vapour lamp was used in all subsequent experiments, and in view of the fact that glass apparatus was employed, the light from the lamp in the regions 436, 405, and 365 μμ actually reached and was partly absorbed by the glyoxal. With this lamp the rate of decrease of pressure was greater than with the filament lamp, and the change

FIG. 2.

was nearly complete in 20 mins., but, although the pressure tended asymptotically to approximately half the initial value, even after 4 hours' illumination it did not quite reach this value. The filament lamp gave similar results. Typical curves are shown in Fig. 2.

The fall of pressure in the first half-minute was always less than in the succeeding half-minute, a fact which is probably due to a slight heating (Draper) effect owing to the onset of photochemical reaction in the vapour.

Over the major part of their courses the curves approximately conform to a bimolecular law with respect to the decomposing glyoxal. Table I shows some typical experiments at 25°, P_t being the observed pressure (in mm.) after t mins. of illumination, and k being the bimolecular velocity coefficient calculated from the equation $k = 1/P_0 t . [(P_0 - P_t)/(P_t - \frac{1}{2}P_0)]$.

During the reaction the green colour of the glyoxal gradually faded and could not be detected after about 1 hour, while a [illegible],

white solid appeared chiefly on the lower surface of the reaction vessel.

The residual gas at the end of the reaction was pumped out and analysed as described below; subsequent illumination of the residual solid failed to produce any further gaseous products.

FIG. 3.

In view of the fact that glyoxal vapour polymerises slowly (Harries and Temme, *loc. cit.*; Harries, *Ber.*, 1913, **46**, 294), a blank run was carried out in which the vapour was not illuminated. The rate of decrease of pressure was small compared with that observed when the vapour was illuminated, as is seen from the "dark" curve shown in Fig. 2.

Analysis of Gaseous Products.—The analysis of three samples of gas collected at the ends of the several runs gave quite concordant results (Table II), and was carried out in an apparatus (Fig. 3) adapted from that used by Dr. M. Brunner (private communication), to whom we wish to express our thanks.

The bulb, *A*, could be filled with mercury from the beaker, *B*, by connecting the wide-mouthed tube, *F*, to a filter pump and opening taps *a* and *b*. The gas was passed from the burette, *D*, to the bulb, *A*, where it was subjected to the action of the requisite reagent, which had been previously introduced into *A* by a pipette with a bent jet. Water introduced from *F* was used for washing the gas before the volume was finally measured in *D*. The form of the bent T-piece, *P*, prevented any gas bubbles from collecting at this joint.

TABLE II.

Gas.	I.	II.	III.
CO	97·0%	97·0%	96·5%
H_2	2·7	2·5	2·5
Unsaturated compounds	0·3	0·4	0·9
Total	100·0	99·9	99·9

It appears from these results that under illumination from the mercury-vapour lamp, through glass, glyoxal decomposes in the main according to a bimolecular reaction, two volumes reacting to give one volume of carbon monoxide and a solid product. We may therefore write the empirical equation

$$2C_2H_2O_2 = CO + C_3H_4O_3 \quad . \quad . \quad . \quad . \quad (1)$$

The fact that hydrogen is also found to a small extent in the decomposition products suggests the reaction

$$C_2H_2O_2 = H_2 + 2CO \quad . \quad . \quad . \quad . \quad (2)$$

and the relative quantities of carbon monoxide and hydrogen in Table II show that about 98·5% of the decomposition may be represented by reaction (1) and 1·5% by reaction (2). The occurrence of reaction (2) would further account for the fact that the exact ratio of 2 : 1 for the initial to final pressures was never quite reached.

Although these equations satisfactorily represent the observed course of the reaction, it seemed possible, as an alternative, that glyoxal might exist as an equilibrium mixture of whole and half molecules $C_2H_2O_2$ and ·CHO (compare N_2O_4 and NO_2), and if this equilibrium were largely in favour of dissociation the facts might be represented by the equation

$$2CHO = CO + CH_2O \longrightarrow [\text{polymerised product}] \quad . \quad (3)$$

This view was tested by a determination of the vapour density of glyoxal. By weighing a dry bulb of known volume first full of air, and then full of glyoxal vapour at a known temperature and pressure, the molecular weight was found to be 58·7, corresponding closely to the formula $C_2H_2O_2$ (Calc. : M, 58·0), and therefore renders inadmissible any explanation of the facts based on thermal dissociation of the glyoxal.

(B) *The Nature of the Solid Product.*

The white solid produced in the reaction vessel was difficult to separate, since it adhered strongly as a glassy skin to the surface. It was slowly but extremely soluble in water, and easily soluble in alcohol, producing uncrystallisable solutions. It was slightly soluble in ether and acetone and insoluble in benzene. On heating, it decomposed without melting at 200°. It was somewhat hygroscopic, and always acquired moisture during attempts to scrape it from the surface of the vessel. In the earlier work it was therefore extracted by absolute alcohol, the solvent being subsequently removed as completely as possible by distillation first under reduced pressure at 30° and finally at 60° under a high vacuum.

It was found, however, that the weight of solid extracted in this way was always somewhat greater than that to be expected from equation (1) and the known quantities of glyoxal reacting, and it seemed probable that some combination had occurred between the original solid and the alcohol, a conclusion which received further confirmation from the analytical data below. Moreover, the alcoholic extract was much more hygroscopic than the original white solid.

In later work, the white solid was removed from the reaction vessel by cutting the latter into sections and scraping vigorously with a sharp knife. The *substance* so obtained was then dried to a constant weight at 75°/1 × 10^{-4} mm., whereby it lost 3·1% of its weight during 2 days. (Found, for dried material: C, 40·5; H, 4·3. $C_3H_4O_3$ requires C, 40·9; H, 4·6%).

The *substance* extracted by alcohol was analysed by three separate micro-estimations, two of which were kindly carried out for us by Professor Haworth, F.R.S. (Found: C, 42·8, 42·6, 42·4; H, 5·7, 5·6, 5·5. $C_{11}H_{18}O_{10}$ requires C, 42·6; H, 5·8%), and it therefore seems clear that the composition of the product is changed by reaction with alcohol during the process of extraction.

Molecular Weight.—The molecular weight of the solid in aqueous solution was determined by the Beckmann freezing-point method. On account of the small amount of material available it was necessary to work with solutions of about 0·05 g. of solid in 7 g. of water. Control experiments on similar quantities of purified glucose ($C_6H_{12}O_6,H_2O$) or sucrose and water constantly gave results for the molecular weights within 8% of the theoretical. Three series of determinations with the solid scraped from the reaction tube gave 332, 365, and 342 for the initial value of the molecular weight. This value decreased progressively with time until, in the latter two cases, final constant values of 90·8 ± 5 and 89·5 ± 5 were obtained. The following figures indicate the results of a typical experiment, the temperature being raised to 16° between each determination :

Wt. of solid, 0·0424 g.; wt. of water, 6·59 g.

Age of solution (mins.)	30	70	100	150	220	270	∞
Mean lowering of f. p.	0·035°	0·0525°	0·055°	0·0605°	0·069°	0·077°	0·134°
Molecular weight	342	288	218	198	173	155	89·5

Since the molecular weight of $C_3H_4O_3$ is 88, it appears that the polymeric substance deposited in the reaction vessel changes in solution to give the monomeric form. In view of the slow rate of solution, an hour being sometimes required at room temperature,

it is not possible to make any certain deductions as to the molecular weight of the polymerised form, for considerable depolymerisation may have occurred before the initial readings are taken.

Further determinations were carried out on the alcoholic extract; two experiments gave mean values of 300 and 308, whence, in conjunction with the analytical data, we conclude $C_{11}H_{18}O_{10}$ or $(C_3H_4O_2)_3,C_2H_6O$ (Calc.: M, 310) to be the formula of the extracted solid. The molecular weight of this substance changed on standing, giving final values of 98 ± 5 and 102 ± 5, and attaining the final value more quickly if the solution was warmed to 35°. This figure is somewhat higher than that for the white solid itself, a result which suggests that the molecule of alcohol associated with the polymerised molecule remains attached to one of the depolymerised forms, so that the apparent molecular weight falls to one-third of its original value.

Pseudo-acidic Character of the White Solid.—In an aqueous solution of the solid scraped from the reaction vessel, a gradual development of acidity occurred, even when the solution was kept in an atmosphere of hydrogen. This slow change took place at the ordinary temperature over a period of weeks, and was later traced to the fact that the monomeric product exists in two forms, one of which is strongly acidic. The equilibrium mixture of the two exhibits the phenomenon of progressive neutralisation similar to that described by Kling (*Compt. rend.*, 1905, **140**, 1256) for hydroxyacetone, the slow development of acidity being due to the slowness of the change of the non-acidic to the acidic form. This change takes place much more rapidly at higher temperatures, and complete titration of the mixture can be effected in less than an hour at 100°. In these experiments, the most satisfactory end-point was obtained with litmus, although fairly satisfactory results were also obtained with phenolphthalein.

As an example, the following experiment may be recorded: A solution of 0·0258 g. of the white solid in 10 c.c. of water required 0·9 c.c. of N/20-sodium hydroxide for neutralisation (litmus). On continued boiling, the titre increased progressively to a final value of 5·15 c.c. in the course of 1 hour. These figures give an initial equivalent of 570 and a final equivalent of 100, but slight decomposition had occurred at the end of the experiment. Another experiment, with smaller quantities and N/100-alkali, gave an initial equivalent of 440 and a final value of 88, whilst a third experiment gave 650 and 86, respectively. The first and third experiments were made with fresh solutions; the second, however, was done with a solution which had stood for 13 days and in which equilibrium had probably become established. Therefore

and 88 be taken as the most probable initial and final equivalents, it would appear that at equilibrium about 20% of the dissolved substance is in the acid form.

The equivalent of the acid form was further measured by heating the white solid under reflux on the water-bath with excess of sodium hydroxide for about 40 mins. Back titration with standard hydrochloric acid gave values of 94 ± 10 and 99 ± 10 for the equivalent. The results of these and the previous experiments are not quite accurate owing to the fact that the white solid is slightly decomposed by continued boiling, giving a brown solution, but the values obtained are in sufficiently close agreement with the theoretical value of 88 for $C_3H_4O_3$, and with the cryoscopic value of 90.

The evidence for the tautomerism of the monomeric substance in solution is further supported by an instantaneous reversible colour change which the solution undergoes on treatment with acids and alkalis. A drop of *N*-sodium hydroxide produces a bright yellow coloration which is immediately discharged on neutralisation by *N*-hydrochloric acid. This colour change can be repeated in the same specimen indefinitely. In addition, bromine water added to the aqueous solution drop by drop is at first instantly decolorised, whilst further quantities react slowly.

The sodium salt was prepared by dissolving together equivalent quantities of the white solid and sodium carbonate in the smallest possible quantity of water. The whole was kept at 60° for 6 hours, the colour of the solution turning gradually from lemon-yellow to dark red. A drop of this red solution on dilution gave a lemon-yellow solution, the colour of which was discharged by acidification with hydrochloric acid, and it was therefore concluded that the development of the red colour corresponded with the progressive neutralisation of the pseudo-acid and the gradual increase in concentration of its sodium salt. When the red solution was allowed to evaporate slowly in a desiccator over phosphoric oxide, it gradually became more viscous, and finally dried to a red, glassy substance without crystallising. This product was very hygroscopic, absorbing water from the air to form a red, treacly mass. In dilute solution it was yellow, the colour being discharged by acidification.

Reducing Properties of the White Solid.—The aqueous solution, in addition to its action with bromine water, showed other strong reducing actions. It apparently converted ferric into ferrous chloride, and reduced Benedict's and Fehling's solutions in the cold, thus differing from glyoxal, which does not react with Fehling's solution. These reactions indicate the existence of an aldehyde group in the molecule, and this conclusion was confirmed by the

observation that the solution readily reacts with phenylhydrazine (see below). The aldehyde group was estimated by the method of Cumming, Hopper, and Wheeler ("Systematic Organic Chemistry," 1923, 479): an excess of standard potassium bisulphite was added to a known quantity of the aqueous solution of the "alcoholic extract," and the excess titrated with iodine. Two separate determinations gave equivalents of 102 and 96 referred to one aldehyde group, in good agreement with the theoretical value $\frac{1}{3} \times 310 = 103$ for the depolymerised form of the alcoholic extract.

These results are satisfactorily explained if, by analogy with Kling's formulæ for hydroxyacetone, (I) and (II), we adopt the

CH_3	CH_3	CHO	CHO
CO ⇌	C·OH	CO ⇌	C·OH
CH_2·OH	CH·OH	CH_2·OH	CH·OH
(I; neutral.)	(II; acid.)	(III; neutral.)	(IV; acid.)

formulæ (III) and (IV) as representing the desmotropic forms of the monomeric glyoxal product. The source of the acidity is to be sought in the hydroxymethylene group, of which the tendency to develop strongly acidic properties when in combination with two electronegative groups is well known. For example, hydroxyacetone, hydroxymethylenecamphor, acetylacetone, acetoacetic and malonic esters all approach, and in some cases surpass, the monocarboxylic acids in strength, and may be represented as derivatives of formic acid by the general structure CXX':CH·OH (Claisen, *Annalen*, 1897, **297**, 1; *Ber.*, 1893, **26**, 2731). Just as in the case of hydroxyacetone, however, so in the present instance, the change of the neutral into the acid form is slow, so that complete neutralisation by alkali only takes place gradually.

The micro-preparation of the following derivatives confirms the structure assigned to the decomposition product.

Quinoxaline Derivative.—0·04 G. of the white solid was dissolved in 1 c.c. of water, kept at 40° until depolymerised, mixed with 0·05 g. of recrystallised *o*-phenylenediamine dissolved in 1 c.c. of water, and the whole warmed to 60°. The yellow precipitate which formed rapidly was recrystallised from aqueous alcohol, and then had m. p. 165° (Found, by microanalysis: N, 15·3. $C_9H_8ON_2,H_2O$ requires N, 15·7%); it was somewhat soluble in both hot and cold water, and dissolved easily in dilute hydrochloric acid to give a brown solution from which it was reprecipitated by soda. This condensation may be taken as proof of the juxtaposition of two carbonyl groups in the molecule.

Reaction with Phenylhydrazine.—The aqueous solution of the white solid when added to a solution of redistilled phenylhy[illegible]

in 50% acetic acid gave *in the cold* a bright yellow precipitate which, when separated and recrystallised from aqueous alcohol, had m. p. 161° (Found. by microanalysis : C, 70·3; H, 5·9; N, 23·0. Calc. for $C_{21}H_{20}N_6$: C, 70·8; H, 5·6; N, 23·6%). If the reaction was carried out on a water-bath, the yellow precipitate first obtained rapidly turned brownish-red, and after recrystallisation from aqueous alcohol melted at 132° (Found : C, 70·2; H, 5·8; N, 23·0%). It would appear that these two products have the same composition.

The triphenylhydrazone of mesoxalic dialdehyde,

$$NHPh{\cdot}N{:}C(CH{:}N{\cdot}NHPh)_2,$$

has been obtained by von Pechmann (*Ber.*, 1891, **24**, 3257) as a yellow substance, m. p. 166°, and by Harries and Türk (*Ber.*, 1905, **38**, 1636) as a brown substance, m. p. 156°; but in view of the method of preparation used by von Pechmann, it seems that his compound is better represented by the isomeric azo-formula $NHPh{\cdot}N{:}C(CH_2{\cdot}N{:}NPh)_2$. It is therefore probable that our condensation products consist largely of these two isomeric substances.

As has already been seen, however, the white solid in solution gives an equilibrium mixture of two isomeric substances, and the possibility of the formation of the monophenylhydrazone of the *aci*-form, which is present to the extent of about 20%, must not be overlooked. The product of reaction with phenylhydrazine would thus contain a small quantity of the substance

$$NHPh{\cdot}N{:}CH{\cdot}C(OH){:}CH{\cdot}OH;$$

indeed, an admixture of 7% of this compound with the triphenylhydrazone would have the composition C, 70·1; H, 5·6; N, 23·0%, which is in close agreement with the analytical figures given above. A partial confirmation of this view was obtained by the observation that a small portion of both the yellow and the red product could be extracted by cold sodium hydroxide to give a yellow solution. Acidification turned this solution cloudy and discharged its colour, which was regenerated by the addition of alkali. Continued action of caustic soda on the original phenylhydrazine derivatives did not extract any further material, so it appears probable that it is the monophenylhydrazone of the enolic form which is thus extracted

The reaction with phenylhydrazine is in agreement with the formulæ proposed for the white solid if we assume that the predominant (non-acidic) form of the latter is capable of undergoing an "osazone" oxidation to form the triphenylhydrazone in the cold, and that at the same time the *aci*-form reacts to form a monophenylhydrazide in smaller quantity. This result is consistent with the fact that the rate of change of the one form of the white solid into the other is very slow.

Reaction with Hydroxylamine.—0·093 G. of the white solid, dissolved in 0·5 c.c. of water, was mixed with 0·16 g. of hydroxylamine hydrochloride dissolved in 0·5 c.c. of water and warmed; the mixture turned brown. 0·12 G. of sodium carbonate in 1 c.c. of water was then added, and after the effervescence had subsided the solution was warmed and allowed to stand for 24 hours. Two extractions of the clear brown solution with ether then yielded 0·053 g. of a white solid, m. p. 168° (decomp.) after drying under a high vacuum. It was soluble with difficulty in water and dilute hydrochloric acid, but easily soluble in soda. Its aqueous solution produced a dark red colour on warming with dilute cobalt acetate in the presence of sodium acetate, and sodium hydroxide then precipitated a green base, which redissolved to a dark red solution on acidification with hydrochloric acid. In all these respects the product acted like a glyoxime and it is believed that its structure corresponds to hydroxymethylglyoxime, $CH_2(OH)\cdot C(:N\cdot OH)\cdot CH:N\cdot OH$.

(C) *The Kinetics of the Change.*

The absorption spectrum of glyoxal in the blue, violet, and near ultra-violet shows fine structure (see p. 2830), and in accordance with spectroscopic theory we must conclude that no spontaneous dissociation of the molecule takes place as the result of light absorption. The alternative, that a molecule of photo-activated glyoxal reacts with an inactive molecule, is therefore to be preferred, and the bimolecular nature of the reaction shows it to be conditioned by the probability of collision between active and inactive molecules. Thus, if g and g' represent the concentrations of inactive and active glyoxal molecules respectively, we have, at equilibrium

$$dg'/dt = k_1Ig - k_2gg' - k_3g' = 0,$$

where k_1 refers to activation, k_2 to reaction, and k_3 to deactivation of glyoxal molecules, and I represents the intensity of illumination. Hence $g' = k_1Ig/(k_2g + k_3)$, and the rate of reaction of glyoxal is therefore

$$-dg/dt = k_2gg' = k_1k_2Ig^2/(k_2g + k_3)$$

whence, if k_3 is large compared with k_2, the measurable reaction will be approximately bimolecular.

The final elucidation of the mechanism must await a further investigation of the quantum kinetics of this reaction, which is now being carried out.

Summary.

Glyoxal gas decomposes in the light of the mercury vapour lamp, probably through the agency of the blue, violet, and ultra-violet light at 3650 Å.U. The main reaction involves a bimol[illegible]

change, two volumes of glyoxal giving one volume of carbon monoxide and a polymerised solid product:

$$2C_2H_2O_2 = CO + (C_3H_4O_3) \longrightarrow [\text{polymerised product}].$$

A second reaction to the extent of about 1·5% of the total change probably occurs with the production of hydrogen:

$$2C_2H_2O_2 = 2CO + H_2.$$

The solid product and its derivatives have been investigated, and its chemical properties, composition, and molecular weight are in accord with its representation as a polymeride of the hitherto unknown glycerosone to which it is hydrolysed in aqueous and acid solution.

The properties of glycerosone further suggest that in aqueous solution it exists in tautomeric equilibrium with an acidic hydroxymethylene form (III and IV), in analogy with other substances of this type.

The kinetics of the photochemical reaction is discussed.

We desire to express our thanks to Sir Robert Robertson, F.R.S., for granting facilities to one of us (J. G. A. G.) for continuing the cryoscopic experiments at the Government Laboratory. Our thanks are also due to the Governing Body of Emmanuel College, Cambridge, for assistance towards the maintenance of one of us (J. G. A. G.) while the work was in progress.

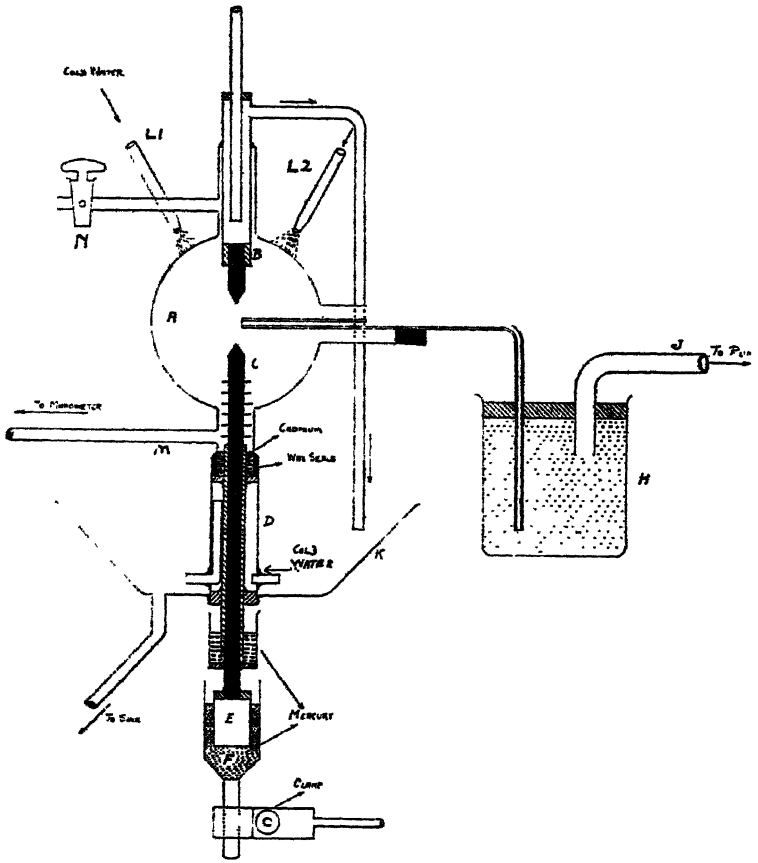
CCCLXXIV.—*On Active Nitrogen. Part VI. The Formation of Iron Nitride in the Iron–Nitrogen Arc.*

By Eric John Baxter Willey.

In the course of an investigation upon the causes of brittleness in electric arc welds, it was found (Willey, *J. Soc. Chem. Ind.*, 1924, **43**, 263) that when an arc is burned between poles of iron in an atmosphere of nitrogen the deposit forming on the walls of the vessel contains iron nitride to the extent of *ca.* 2%. Moreover, the electrodes absorbed nitrogen and retained it very tenaciously. It was suggested that this is due to the formation of iron nitride through the interaction of active nitrogen and iron vapour or the finely divided metal evaporated from the electrodes, and Dr. Rideal later pointed out to the author that this comparatively small nitride content

might be greatly increased if the vapours were quickly removed from the high-temperature zone and chilled to prevent a subsequent decomposition of the nitride, which is known to be somewhat unstable. Fowler (J., 1901, **79**, 285) found that Fe_4N_2 begins to decompose into its elements at about 600°, but Noyes and Smith (*J. Amer. Chem. Soc.*, 1921, **43**, 475) have shown that the equilibrium nitrogen pressure for the same substance is about 41,000 atmospheres at 460°, good agreement being obtained between the observed values and those calculated by an application of the Nernst heat theorem to the data of Fowler and Hartog (J., 1901, **79**, 299) upon the heat of formation of Fe_4N_2 (3040 cals./g.-mol.). Hägg, however (*Nature*, 1928, **121**, 826), has concluded from *X*-ray examinations that this "nitride" is not a definite compound but rather a solid solution of nitrogen in iron (compare Fry, *Krupp'sche Monatsh.*, 1923, **4**, 137; *Stahl u. Eisen*, 1923, **43**, 1271). The matter was therefore shortly investigated and Rideal's prediction verified.



Experimental.

Nitrogen, purified and freed from oxygen by either hot copper or phosphorus, was led to the quartz globe, *A*, which was provided with three arms each with side tubes as shown. The upper electrode, *B*, was of Armco iron rod, about $\frac{1}{8}$" in diameter and screwed into the solid ends of the $\frac{1}{2}$" brass rod, which was bored out and fitted for water cooling as shown. The lower electrode, *C*, passed first through the water-cooled gland, *D* (made by accurate boring of another brass rod), provided with a mercury seal carried on the electrode as shown; access of mercury vapour to the bulb was prevented by a few carefully packed fragments of cadmium metal above the gland. Cooling fins on the electrode dissipated so much heat that the rod below *D* was rarely more than just warm, even when no water-cooling was employed on the gland. The steel float, *E*, rested on mercury in the column *F*, the height being adjustable by a levelling tube and reservoir. At *G* a quartz capillary, of 1·5 mm. bore, led to the stoppered litre beaker *H*, which was loosely packed with glass wool and fitted with an outlet tube, *J*, through which the nitrogen was drawn to a motor-driven oil pump of large capacity. The capillary was adjusted in trial runs so that it was in contact with the particular zone of the arc from which it was desired to draw the vapours. The electrodes and gland were fixed in position with Faraday wax, as was the tinned-iron funnel, *K*, to which the cooling water flowed; the bulb itself was also cooled by jets of water at *L*1 and *L*2. A manometer was also provided [illegible] tube *M*.

Starting of the arc was effected by raising the reserv[illegible]

the electrodes made contact; the level was then quickly dropped. It may be mentioned that, as found before, the arcs did not burn well after about an hour or so; this is clearly due to changes in the composition of the electrode tips owing to absorption of nitrogen, leading to a decrease in their ability to emit electrons and to give

FIG. 1.

iron vapour, which carries a large proportion of the current in the arc.

In the experiments, the tap, *N*, was closed, and the pump started to evacuate the system to 0·5 mm., the mercury reservoir being lowered, after which *N* was opened, nitrogen admitted, and the flow adjusted until a rate of 10 litres per hour was obtained, the

pressure being about 730 mm. The arc was then struck and allowed to burn until a suitable quantity of the iron–iron nitride mixture had collected in *H*, after which the experiment was stopped.

The deposit was then separated from the glass wool by means of a magnet, or in some cases the mixed wool and deposit were weighed, and treated with dilute sulphuric acid, and the wool was separated by decantation, washed until no iron remained, dried thoroughly and reweighed, the amount of deposit being obtained by difference. The iron was determined by permanganate and the nitrogen by a Kjeldahl method, the ammonia in the distillate being either titrated back with *N*/50-alkali (methyl-red being used as indicator), or, if the samples were small, determined colorimetrically; the results were calculated to iron and iron nitride.

The amount of nitride present decreased from the metal-vapour zone outwards; at the edge of the brilliantly blue inner zone of the arc 12—15% of the iron was present as nitride, Fe_4N_2, whilst at the outer edge of the arc the proportion had fallen to 6—8%, and the sublimate obtained from the walls of the bulb when a gentle stream of gas (1—2 litres per hour) was maintained contained some 2—3%, as found in the previous experiments. Preliminary studies of the effect of power input on the yields showed that, whilst the distribution did not alter much, the actual quantities of nitride obtained from an arc of 1·5 cm. length varied roughly as the amperage; the currents employed were from 3—10 amps. at 35 volts and upwards.

Discussion.

The principal interest of these results lies in their bearing on the experiments in which evidence was obtained that nitrogen may be chemically active and yet show no luminosity (see Part IV, J., 1927, 2831). These have recently been largely confirmed by Kaplan and Cario's observation (*Nature*, 1928, **121**, 906) that the *D* lines in the sodium spectrum can be excited by the non-luminous active nitrogen, of which the existence had been inferred by the present author from the ability of the gas to react with nitric oxide and undergo its characteristic exothermic catalytic decay at copper oxide surfaces even when no glow is visible.

The arc in nitrogen is a brilliant bluish-white, with a reddish outer zone which may easily escape detection by reason of its comparative faintness. Examination of the arc light by means of a Hilger spectrometer showed that the bands (especially in the yellow) which are characteristic of the nitrogen afterglow spectrum could not be detected visually; they may have been masked by the [illegible] lines which are abundantly developed, but as these are [illegible] paratively few in the yellow, the afterglow bands would [illegible]

expected to appear. It may be that the reaction between the active nitrogen and the iron is so rapid that the quantity of the former present in the free state remains very low and hence cannot be seen, but the failure to obtain evidence of a glow would suggest either (1) that if the Rayleigh nitrogen be the active form it is here non-luminous, or (2) that, under the more intense mean-current and temperature conditions obtaining in the arc as compared with the condenser discharge, another and chemically more active modification of nitrogen such as Lowry's (J., 1912, **101**, 1152) is being produced.

The author's acknowledgments are due to Dr. Rideal for suggesting this investigation, to Mr. R. E. Stonebridge, who made the gland and float system, and to his assistant, Mr. R. Southward, for the accompanying diagram.

The experiments were carried out in the Laboratory of Physical Chemistry, Cambridge, early in 1925, and, although they had to be abandoned whilst still incomplete, it is hoped that they may lead to further investigations on reactions in the electric discharge—a subject which promises to be of much interest.

NORTHWICH, CHESHIRE. [*Received, September 5th*, 1928.]

CCCLXXV.—*Acid and Salt Effects in Catalysed Reactions. Part XVII. The Variation of the Catalytic Activity of an Acid with its Concentration, and the Determination of Ionisation Constants.*

By HARRY MEDFORTH DAWSON, GEORGE VINCENT HALL, and ARTHUR KEY.

THE facts established by various workers in the investigation of the dependence of the catalysing power of an acid on its concentration (Goldschmidt, *Z. physikal. Chem.*, 1910, **70**, 627; Goldschmidt and Thuesen, *Z. Elektrochem.*, 1911, **17**, 684; Bredig, Millar, and Braune, *ibid.*, 1912, **18**, 535; Snethlage, *ibid.*, p. 539; Dawson and Powis, J., 1913, **103**, 2135; Taylor, *Medd. K. Vetensk-apsakad. Nobel-Inst.*, 2, 34, 35, 37) led to the view that the catalytic effects are jointly due to the action of the hydrogen ion and of the undissociated acid. The sum total of the evidence for this joint action was such as to afford a very substantial basis for what became generally known as the dual theory of acid catalysis. In particular, it may be recalled that observations on the acetone–iodine reaction

with acetic, chloroacetic, αβ-dichlorobutyric, dichloroacetic, and hydrochloric acids gave in all cases the same value for the catalytic activity of the hydrogen ion, whilst the coefficients for the undissociated acid molecules varied very largely according to the nature of the acid.

The dual theory marks a well-defined stage in the development of the modern view, according to which catalytic effects are to be attributed to positively charged " hydrogen " and similar complex kations, to neutral molecules, and also to negatively charged anions —in short, to all those molecular entities which may act either as proton donators or proton acceptors (compare Lowry, J., 1927, 2554; Brönsted, *J. Physical Chem.*, 1926, **30**, 777). For an aqueous solution which contains an acid HA and the corresponding anion A^-, the equation for the catalytic effect may be written

$$v = k_h[H^+] + k_a[A^-] + k_m[HA] + k_{OH}[OH^-] + k_w[H_2O] . \quad (1)$$

in which the relative values of the respective catalytic coefficients vary widely with the nature of the catalysed reaction. It is possible, for instance, that k_{OH} may be of the same order of magnitude or millions of times greater than k_h, and that the action of the undissociated water molecules as measured by k_w may be negligibly small or may represent a very important part of the observed catalytic effect. In such circumstances, it is apparent that all acid-catalysed reactions do not lend themselves to the quantitative investigation of the individual catalytic effects which are produced by the undissociated acid HA and the corresponding anion A^-. Generally speaking, favourable conditions will not be attained if the ratios k_m/k_h and k_a/k_h are very much less than about 0·01.

For a given reaction, the magnitude of these ratios depends on the ionisation constant of the catalysing acid. As the ionisation constant increases, the value of k_m increases, whilst that of k_a diminishes. For very weak acids it may therefore be possible to determine k_a, but not k_m, whilst the converse may be true for relatively strong acids. The fact that the acetone–iodine reaction affords k_m/k_h and k_a/k_h ratios of suitable magnitude in the case of moderately weak acids is largely responsible for the discovery of those simple relations which have found expression in the generalised form of the catalytic catenary.

The results to be described are concerned with the catalytic activity of a series of acids of varying strength, and it will be shown that the change in the catalysing power with the concentration affords a measure of k_m and also a value for the ionisation constant of the acid. The measurements relate to the acetone–iodine reaction at 25°, and it may be noted at the outset that the

value of k_a/k_h is about 0·01. On account of the autocatalytic action of the hydriodic acid which is produced in the reaction, it is not possible to determine with the requisite accuracy the initial reaction velocity when the ionisation constant of the catalysing acid is much less than $K = 10^{-5}$.

For a solution which contains c mols. of HA per litre, the equation for the reaction velocity may be written

$$\begin{aligned} v &= k_h[H^+] + k_a[A^-] + k_m[HA] \\ &= (k_h + k_a - k_m)[H^+] + k_m c \quad . \quad . \quad . \quad . \quad (2) \end{aligned}$$

If the acid is sufficiently weak, the hydrogen-ion concentration for the range of solutions $c = 0{\cdot}01$ to $c = 0{\cdot}5$ is given with close approximation by $[H^+] = \sqrt{Kc}$, and equation (2) may be written

$$v/\sqrt{c} = (k_h + k_a - k_m)\sqrt{K} + k_m\sqrt{c} \quad . \quad . \quad . \quad (3)$$

according to which $v/\sqrt{c}$ is a linear function of $\sqrt{c}$. The slope of this line gives k_m, and its intercept on the zero ordinate yields $(k_h + k_a - k_m)\sqrt{K}$. As already indicated, k_a can be neglected without serious error, but if required its value can be determined by methods which have been previously described. Since k_h is known, it follows that the intercept affords a measure of the ionisation constant K. The accuracy of the value is obviously limited by the degree of approximation which is involved in the substitution of $\sqrt{Kc}$ for $[H^+]$, and the error thereby introduced increases with the magnitude of K. The value of K derived from equation (3) may, however, be used as a preliminary value in proceeding to the next step in the process of evaluation.

In this further step, the value of $[H^+]$ in equation (2) is assumed to be given by the mass-law expression $[H^+] = c\alpha = \sqrt{Kc(1 - \alpha)}$, where α is the degree of ionisation of the acid and K the ionisation constant derived from equation (3). From equation (2), which may be put in the form

$$v = (k_h + k_a)[H^+] + k_m[HA],$$

we then obtain by substitution for $[H^+]$

$$v/\sqrt{c(1 - \alpha)} = (k_h + k_a)\sqrt{K} + k_m\sqrt{c(1 - \alpha)} \quad . \quad . \quad (4)$$

which yields a straight line when $v/\sqrt{c(1 - \alpha)}$ is plotted against $\sqrt{c(1 - \alpha)}$. The intercept of this line on the zero ordinate obviously leads to a value of K which is greater than that derived from the graph corresponding with equation (3), and at the same time the increased value of the intercept implies a smaller value of k_m.

If necessary, the second value of K may be used to derive a new series of values of $\sqrt{c(1 - \alpha)}$, and the procedure followed in the

second stage may be repeated. When the strength of the acid is such that the relation $[H^+] = \sqrt{Kc}$ is not even approximately true, the first step in the process may be omitted and the catalytic data applied directly to equation (4) with values of $\sqrt{c(1-\alpha)}$ derived from an approximate ionisation constant afforded by conductivity or other measurements. It should be noted that equation (4) may be written in the alternative form

$$v/c\alpha = k_h + k_a + k_m c\alpha/K \quad . \quad . \quad . \quad . \quad (5)$$

according to which $v/c\alpha$ is a linear function of $c\alpha$. This form affords a convenient method for the determination of one of the quantities K or k_m if the other is known, but is not so suitable for the evaluation of both K and k_m.

The results which have been obtained in the application of the above method are shown in the following tables, of which the order is determined by the magnitude of K. The first line of figures gives the concentration of the acid in mols. per litre, the second gives the observed initial reaction velocity with an acetone concentration of 20 c.c. per litre, the third gives the values of $v/\sqrt{c}$ or $v/\sqrt{c(1-\alpha)}$, and the fourth the corresponding values calculated from equation (3) or (4).

Propionic Acid.

c	0·01	0·02	0·05	0·1	0·2	0·4	0·5
$v \cdot 10^6$	0·181	0·269	0·449	0·664	0·997	1·545	1·76
$v/\sqrt{c} \cdot 10^6$	1·81	1·90	2·01	2·10	2·23	2·44	2·49
$v/\sqrt{c} \cdot 10^6$ (calc.) ...	1·85	1·90	1·99	2·09	2·23	2·44	2·52

The slope of the line when $v/\sqrt{c}$ is plotted against $\sqrt{c}$ gives $k_m = 1{\cdot}10 \times 10^{-6}$, and the intercept on the zero ordinate $(k_h + k_a - k_m)\sqrt{K} = 1{\cdot}74 \times 10^{-6}$. Since $k_h = 465 \times 10^{-6}$ and $k_a = 4 \times 10^{-6}$, this gives $K = (1{\cdot}74/468)^2 = 1{\cdot}38 \times 10^{-5}$. The calculated values of $v/\sqrt{c}$ are those derived from $10^6 \times v/\sqrt{c} = 1{\cdot}74 + 1{\cdot}10\sqrt{c}$.

Acetic Acid.

c	0·01	0·02	0·05	0·1	0·2	0·4	0·8
$v \cdot 10^6$	0·216	0·317	0·512	0·770	1·17	1·79	2·85
$v/\sqrt{c} \cdot 10^6$	2·16	2·24	2·29	2·43	2·62	2·83	3·18
$v/\sqrt{c} \cdot 10^6$ (calc.) ...	2·14	2·20	2·31	2·44	2·61	2·86	3·22

The slope of the $v/\sqrt{c}$ and $\sqrt{c}$ line gives $k_m = 1{\cdot}35 \times 10^{-6}$ and the intercept $= 2{\cdot}01 \times 10^{-6}$. Since $k_a = 4 \times 10^{-6}$, $K = (2{\cdot}01/467)^2 = 1{\cdot}85 \times 10^{-5}$. The calculated values of $v/\sqrt{c}$ are given by $v/\sqrt{c} \cdot 10^6 = 2{\cdot}01 + 1{\cdot}35\sqrt{c}$.

Succinic Acid.

c	0·01	0·02	0·05	0·1	0·2	0·4	0·5
$v \cdot 10^6$	0·388	0·588	1·030	1·60	2·47	4·02	4·74
$v/\sqrt{c(1-\alpha)} \cdot 10^6$	4·04	4·27	4·69	5·12	5·57	6·40	6·74
$v/\sqrt{c(1-\alpha)} \cdot 10^6$ (calc.)	4·11	4·29	4·65	5·04	5·60	6·40	6·72

The first-stage plot of $v/\sqrt{c}$ against $\sqrt{c}$ gives $k_m = 4{\cdot}35 \times 10^{-6}$ and $(k_h + k_a - k_m)\sqrt{K} = 3{\cdot}65 \times 10^{-6}$. Since k_a is approximately 1×10^{-6}, this gives a preliminary value of $K = (3{\cdot}65/462)^2 = 6{\cdot}24 \times 10^{-5}$. From this the values of $v/\sqrt{c(1-\alpha)}$ in the third line are derived, and the plot of these against $\sqrt{c(1-\alpha)}$ gives $k_m = 4{\cdot}30 \times 10^{-6}$ and the intercept $(k_h + k_a)\sqrt{K} = 3{\cdot}70 \times 10^{-6}$, from which $K = (3{\cdot}70/466)^2 = 6{\cdot}30 \times 10^{-5}$. The values in the last line are those calculated from $v/\sqrt{c(1-\alpha)} \cdot 10^6 = 3{\cdot}70 + 4{\cdot}30\sqrt{c(1-\alpha)}$.

β-Chloropropionic Acid.

c	0·01	0·02	0·05	0·1	0·2	0·5
$v \cdot 10^6$	0·473	0·710	1·20	1·81	2·79	5·02
$v/\sqrt{c(1-\alpha)} \cdot 10^6$	4·96	5·20	5·49	5·81	6·31	7·15
$v/\sqrt{c(1-\alpha)} \cdot 10^6$ (calc.)	5·03	5·19	5·49	5·83	6·31	7·28

The preliminary plot gives $k_m = 3{\cdot}85 \times 10^{-6}$ and $(k_h + k_a - k_m)\sqrt{K} = 4{\cdot}48 \times 10^{-6}$, whence $K = 0{\cdot}94 \times 10^{-4}$. From the latter the values of $v/\sqrt{c(1-\alpha)}$ in the third line have been derived, and the plot of these against $\sqrt{c(1-\alpha)}$ gives $k_m = 3{\cdot}7 \times 10^{-6}$ and $(k_h + k_a)\sqrt{K} = 4{\cdot}68$, or $K = (4{\cdot}68/465)^2 = 1{\cdot}01 \times 10^{-4}$. The numbers in the fourth line are those calculated by use of equation (4).

The value of $K = 0{\cdot}86 \times 10^{-4}$ obtained by Lichty (*Annalen*, 1910, **319**, 380) from conductivity data is less than those for β-bromopropionic acid ($K = 0{\cdot}98 \times 10^{-4}$; Walden, *Z. physikal. Chem.*, 1892, **10**, 650) and for β-iodopropionic acid ($K = 0{\cdot}90 \times 10^{-4}$; Ostwald, *ibid.*, 1889, **3**, 193), whereas the strength of corresponding halogen-substituted acids normally increases from the iodo- to the chloro-acid. The higher value derived from the catalytic data has been confirmed by new conductivity measurements, which for $v = 16$ to $v = 256$ gave $K = 1{\cdot}04 \times 10^{-4}$.

Glycollic Acid.

c	0·01	0·02	0·05	0·1	0·2	0·4	0·5
$v \cdot 10^6$	0·585	0·882	1·495	2·31	3·61	5·86	6·79
$v/\sqrt{c(1-\alpha)} \cdot 10^6$	6·20	6·50	6·86	7·44	8·18	9·35	9·68
$v/\sqrt{c(1-\alpha)} \cdot 10^6$ (calc.)	6·24	6·47	6·94	7·47	8·21	9·27	9·70

The first-stage plot gives $k_m = 6{\cdot}0 \times 10^{-6}$ and $(k_h + k_a - k_m)\sqrt{K} = 5{\cdot}40 \times 10^{-6}$, whence $K = 1{\cdot}38 \times 10^{-4}$. From this, the

values of $v/\sqrt{c(1-\alpha)}$ in the third line are derived, and the graph of these against $\sqrt{c(1-\alpha)}$ gives $k_m = 5{\cdot}7 \times 10^{-6}$ and $(k_h + k_a)\sqrt{K} = 5{\cdot}70 \times 10^{-6}$, whence $K = (5{\cdot}70/465)^2 = 1{\cdot}50 \times 10^{-4}$. The numbers in the fourth line are those derived from $v/\sqrt{c(1-\alpha)} \cdot 10^6 = 5{\cdot}70 + 5{\cdot}70\sqrt{c(1-\alpha)}$.

Chloroacetic Acid.

c	0·005	0·01	0·02	0·05	0·1	0·2	0·5
$v \cdot 10^6$	1·055	1·655	2·56	4·62	7·31	11·80	23·0
$v/\sqrt{c(1-\alpha)} \cdot 10^6$	19·5	20·0	20·7	22·5	24·5	27·5	33·4
$v/\sqrt{c(1-\alpha)} \cdot 10^6$ (calc.)	19·3	19·9	20·85	22·65	24·7	27·6	33·4

In the case of chloroacetic acid the substitution of $\sqrt{Kc}$ for $[H^+]$ is a very rough approximation, as seen when $v/\sqrt{c}$ is plotted against $\sqrt{c}$, for the points corresponding with the lower acid concentrations fall very considerably below the straight line which reproduces fairly well the data for the three most concentrated solutions. This line gives $k_m = 23{\cdot}5 \times 10^{-6}$ and $(k_h + k_a - k_m)\sqrt{K} = 16{\cdot}0 \times 10^{-6}$, whence $K = 1{\cdot}31 \times 10^{-3}$. From this preliminary value of K, the second stage of the process gives $k_m = 22{\cdot}3 \times 10^{-6}$ and $(k_h + k_a)\sqrt{K} = 17{\cdot}9 \times 10^{-6}$, whence $K = 1{\cdot}48 \times 10^{-3}$. The values of $v/\sqrt{c(1-\alpha)}$ in the third line are derived from the latter and the plot of these numbers against $\sqrt{c(1-\alpha)}$ yields $k_m = 22{\cdot}2 \times 10^{-6}$ and $(k_h + k_a)\sqrt{K} = 18{\cdot}1 \times 10^{-6}$, whence $K = 1{\cdot}51 \times 10^{-3}$. The figures in the fourth line are those given by $v/\sqrt{c(1-\alpha)} \cdot 10^6 = 18{\cdot}10 + 22{\cdot}2\sqrt{c(1-\alpha)}$. Repetition of the second-stage process thus makes but little difference to the values obtained for k_m and K, although chloroacetic acid is not an acid which can be regarded as weak.

In the following table, the results of the measurements are summarised, and for comparison the values of K derived from conductivity measurements are added in the last column.

Acid.	$k_m \times 10^6$.	K (from catalytic data).	K (from conductivity).
Propionic	1·1	$1{\cdot}38 \times 10^{-5}$	$1{\cdot}4 \times 10^{-5}$
Acetic	1·35	$1{\cdot}85 \times 10^{-5}$	$1{\cdot}85 \times 10^{-5}$
Succinic	4·3	$6{\cdot}30 \times 10^{-5}$	$6{\cdot}55 \times 10^{-5}$
β-Chloropropionic	3·7	$1{\cdot}01 \times 10^{-4}$	$1{\cdot}04 \times 10^{-4}$
Glycollic	5·7	$1{\cdot}50 \times 10^{-4}$	$1{\cdot}52 \times 10^{-4}$
Chloroacetic	22·2	$1{\cdot}51 \times 10^{-3}$	$1{\cdot}55 \times 10^{-3}$

From the table it is evident that k_m increases in general with the strength of the acid. The slightly anomalous value for succinic acid may possibly be connected with the fact that this is dibasic, and in other ways not directly comparable with the other members

the series. In all cases the ionisation constants derived from the catalytic data are in close agreement with those given by the conductivity of the acid in dilute solution.

According to equation (2), the hydrogen-ion concentration is given by $[H^+] = (v - k_m c)/(k_h + k_a - k_m)$, and provided k_a and k_m are known, the ionisation constant may be derived by substitution of this value of $[H^+]$ in $K = [H^+]^2/(c - [H^+])$. The result is illustrated by reference to the data for glycollic acid:

c	0·01	0·02	0·05	0·1	0·2	0·4	0·5
$[H^+] . 10^3$ ...	1·15	1·67	2·64	3·79	5·38	7·80	8·58
$K . 10^4$	1·50	1·53	1·47	1·49	1·49	1·55	1·50

Consideration of the Factors which affect the Value of K.

The determination of K and k_m by the method based on equation (4) involves the assumption that the ionisation constant K and the catalytic coefficients k_h, k_a, and k_m are not affected by changes in the concentration of the acid. From experiments on the catalytic activity of acids in solutions of catalytically inert salts (Dawson and Key, this vol., pp. 1239, 1248), it would appear that k_h increases continuously with the salt concentration, whereas k_a and k_m are but slightly affected by changes in the ionic environment. These experiments show, further, that the ionisation constant K increases with the salt concentration to a maximum and then diminishes as the proportion of salt in the solution is further increased.

The ionic concentration of the salt-free solutions with which we are concerned in this paper increases with the total acid concentration, but, in general, the ionic strength ($\mu = c\alpha$) is less than 0·01. In these circumstances, there will be no appreciable alteration in the values of the several catalytic coefficients, but since the ionisation constant increases rapidly with the ionic concentration at low values of the latter, it may be anticipated that K will increase somewhat as the concentration of the acid increases. On the other hand, it is well known that the addition of non-electrolytes to the aqueous solution of a weak electrolyte reduces the ionisation of the latter, and this factor may be expected to play some part in the more concentrated acid solutions. It seems possible, in fact, that the constancy of K, which is indicated by the catalytic data, may be due in some measure to the opposite effects which are produced by the ionised acid and by the non-ionised acid respectively.

Since the thermodynamic ionisation constant K_a is given by

$$K_a = a_{H^+} . a_{A^-}/a_{HA} = (f_+ f_-/f_0) \times [H^+][A^-]/[HA]$$

in which f_0 is approximately equal to unity, the connexion between K and K_a may be written $K = K_a/f_+ f_- = K_a/f_\pm^2$, where $f_\pm$ is the

mean activity coefficient of the ions. Furthermore, the relation between $f_{\pm}$ and the ionic strength μ may be expressed in the form $\log 1/f_{\pm} = a\sqrt{\mu} - b\mu$, in which the second term may be neglected for small values of μ and, in accordance with the Debye–Hückel theory, a may be given the value 0·5 when the ions concerned are univalent. On replacing the ordinary by the natural logarithm, we obtain $\log_e 1/f_{\pm} = 1{\cdot}15\sqrt{\mu}$, whence $K = K_a \cdot e^{2{\cdot}30\sqrt{\mu}}$ or $\sqrt{K} = \sqrt{K_a} \cdot e^{1{\cdot}15\sqrt{ca}}$. When this is introduced into equation (4), the latter takes the form

$$v/\sqrt{c(1-\alpha)} = (k_h + k_a)\sqrt{K_a} \cdot e^{1{\cdot}15\sqrt{ca}} + k_m\sqrt{c(1-\alpha)} \quad . \quad (6)$$

If the limiting ionic strength is taken as 0·01, which is greater than that of any of the solutions used in the catalytic experiments, except for the more concentrated solutions of the chloroacetic acid series, the limiting value of $e^{1{\cdot}15\sqrt{ca}}$ is approximately 1·12, which signifies that an increase of 12% in the value of $v/\sqrt{c(1-\alpha)}$ might conceivably be debited to the change in the ionic environment in proceeding from $\mu = 0$ to $\mu = 0{\cdot}01$. This increase of 12%, although only a small fraction (see tables) of the actually observed increase in $v/\sqrt{c(1-\alpha)}$, represents the maximum increase which can be attributed to the ionic effect, for it takes no account of the opposing influence of the second term in the equation $\log 1/f_{\pm} = a\sqrt{\mu} - b\mu$. The influence of the un-ionised acid in the more concentrated solutions is also ignored. So far as the present series of experiments is concerned, it is perhaps still more important to bear in mind that all the solutions examined contained a small quantity of potassium iodide (0·002 mol. per litre). The presence of the latter diminishes very appreciably the variation of K which may be attributed to the increasing concentration of the ions in passing from the weaker to the stronger solutions. This may be illustrated by reference to the specific case of propionic acid for which $e^{1{\cdot}15\sqrt{\mu}}$ increases from 1·058 for $c = 0{\cdot}01$ to 1·083 for $c = 0{\cdot}5$. The corresponding increase in $e^{1{\cdot}15\sqrt{\mu}}$ for glycollic acid is from 1·065 for $c = 0{\cdot}01$ to 1·12 for $c = 0{\cdot}5$. In such circumstances, it is not difficult to understand that the catalytic data are generally consistent with the assumption of a constant value for K.

In this connexion, attention may be directed to the experimental data obtained by Dawson and Powis (*loc. cit.*) for the much stronger dichloroacetic acid at concentrations between $c = 0{\cdot}01$ and $c = 0{\cdot}2$. In the application of equation (4) to these results, the values of $v/\sqrt{c(1-\alpha)}$ have been derived from $K = 5{\cdot}0 \times 10^{-2}$ (Drucker, *Z. physikal. Chem.*, 1904, **49**, 563):

Dichloroacetic Acid.

c	0·01	0·02	0·05	0·1	0·2
$v \cdot 10^6$	4·10	7·95	18·1	32·7	59·6
$c\alpha$	0·00854	0·0153	0·0309	0·0500	0·0780
$v/\sqrt{c(1-\alpha)} \cdot 10^6$	107·3	116·0	131·0	146·2	170·6
$v/\sqrt{c(1-\alpha)} \cdot 10^6$ (calc.)	110·6	116·7	130·6	147·7	172·8

The plot of $v/\sqrt{c(1-\alpha)}$ against $\sqrt{c(1-\alpha)}$ gives a straight line, the slope of which yields $k_m = 200 \times 10^{-6}$. The numbers in the last horizontal line are those derived from $v/\sqrt{c(1-\alpha)} \cdot 10^6 = 103{\cdot}0 + 200\sqrt{c(1-\alpha)}$. As in the case of the weaker acids, these results indicate that the catalytic data for dichloroacetic acid can be satisfactorily co-ordinated in terms of equation (4) with a constant value of K. It is to be noted, however, that the solutions of dichloroacetic acid contained a larger quantity of potassium iodide, *viz.*, 0·008 mol. per litre. This would certainly tend to reduce the influence of the ionised acid on the value of K. At the same time, the ionic strengths of this series of solutions (see third line of table) are of such magnitude that the second term in the equation $\log 1/f_\pm = a\sqrt{\mu} - b\mu$ cannot entirely be left out of account. Without entering into a more minute discussion of the matter in this paper, we would further suggest that it is improbable that the polarising influence of ionic environment, as measured by a, is independent of the nature of the positive and negative ions, even when these carry the same charge. There is, indeed, a substantial amount of evidence to support the view that such influence is specific even at very low ionic concentrations.

In conclusion, attention may be directed to the very general applicability of the catalytic method as a means of determining the degree of ionisation of an acid. If the values of k_h, k_a, and k_m are known, the method may be applied to solutions of the acid in pure water or in solvents which contain relatively large quantities of catalytically inert salts. The conductivity method fails completely when foreign electrolytes are present in more than very small amounts, and since the mobility of the ions is so largely affected by interionic forces, it is at the best limited to solutions of low ionic strength.

Summary.

The catalytic effects produced by propionic, acetic, succinic, β-chloropropionic, glycollic, and chloroacetic acids have been studied with reference to the variation of the catalysing power with the concentration.

It is shown that the connexion between the reaction velocity and the concentration affords a means of determining the ionisation

constant of the acid as well as the catalytic activity of the undissociated acid.

The ionisation constants derived from the catalytic data are in close agreement with those afforded by the electrical conductivity of dilute solutions of the acids.

In general, the catalytic activity of the undissociated acid increases with the ionisation constant.

The relation between the catalytically determined constant K and the thermodynamic constant K_a is considered in reference to the various factors which affect the value of K under the conditions which obtain in the experimental determinations.

THE UNIVERSITY, LEEDS. [*Received, August 22nd*, 1928.]

CCCLXXVI.—*The Reactions of Hydrogen Chloride with the Dioxides of Selenium and Tellurium between* 0° *and* 170°.

By THOMAS WALLACE PARKER and PERCY LUCOCK ROBINSON.

SELENIUM dioxide has been stated by Ditte (*Compt. rend.*, 1876, **83**, 56) to absorb hydrogen chloride exothermally, forming, (1) at the ordinary temperature, an amber-coloured liquid, SeO_2,HCl, stable below 26°, but evolving hydrogen chloride on warming, and (2) at low temperatures, a transparent yellow solid, $SeO_2,2HCl$, which reverts to SeO_2,HCl on rise of temperature. The formation of $SeO_2,2HCl$ was confirmed by Lenher (*J. Amer. Chem. Soc.*, 1920, **42**, 2498), who, however, did not specify the temperature; by the action of either phosphoric oxide or calcium chloride on this compound, followed by distillation, he prepared selenium oxychloride.

The present authors find that a pale yellow solid approximating closely to $SeO_2,4HCl$ is formed at 0°; when warmed, this loses hydrogen chloride, liquefies completely at 35°, and at 100° is a yellow liquid containing slightly more hydrogen chloride than required by $SeO_2,2HCl$. If the reaction is started at 18°, the resulting material is partly liquid, has the composition $SeO_2,2{\cdot}6HCl$, and behaves like the preceding product when heated to 100°; whereas at 100° material identical with the previous final product is obtained. At 140—170° an amber-coloured liquid is formed of composition $SeO_2,1{\cdot}3HCl$, which on distillation partly decomposes into selenium dioxide and hydrogen chloride, the resulting clear yellow liquid, b. p. 160—170°, d 2·45, having the composition $SeO_2,1{\cdot}8HCl$. Redistillation of this liquid in a vacuum is accompanied by a further partial decomposition, producing a distillate, b. p. 70—80°/15 mm., the analysis of

which agrees with $SeO_2,2HCl$. We therefore conclude that there are two addition compounds, *viz.*, (1) $SeO_2,4HCl$, a yellow solid stable at 0°, and (2) $SeO_2,2HCl$, a yellow liquid, stable up to and partly distillable at 170°. This liquid dissolves hydrogen chloride in amounts varying with temperature.

Ditte (*Compt. rend.*, 1876, **83**, 336) considered that an addition compound, $2TeO_2,3HCl$, was formed by passing dry hydrogen chloride over tellurium dioxide at — 10°, which dissociated at the ordinary temperature, yielding TeO_2,HCl, but he obtained no evidence of $TeO_2,2HCl$ at an intermediate stage; TeO_2,HCl was described as beginning to lose water at 110° and yielding at 300° tellurium oxychloride, $TeOCl_2$, a yellow liquid setting to a crystalline solid. Lenher (*J. Amer. Chem. Soc.*, 1909, **31**, 243) found that the dioxide and hydrogen chloride combined to form $TeO_2,3HCl$ at 0°, and that this was successively converted into $TeO_2,2HCl$ and $TeCl_4$ on heating, but he obtained no evidence of the formation of tellurium oxychloride in any reaction. At 280—300° tellurium dioxide was completely volatilised in a stream of hydrogen chloride, presumably as tetrachloride and steam. The present investigation shows that at 0° hydrogen chloride is absorbed in varying quantities by the dioxide, giving a product, obviously not homogeneous, which loses water continuously with rising temperature when heated in a stream of the gas. There is no evidence that tellurium dioxide forms a definite addition compound within the range 0—150°, the experimental data according more closely with the anticipated behaviour of basic chlorides in the presence of hydrogen chloride.

EXPERIMENTAL.

Tellurium.—The dioxide was prepared by adding successive small quantities of finely powdered tellurium to boiling concentrated nitric acid, decanting the excess of acid, washing the oxide well with water, and drying it first on a steam-bath and then at 110° (Found: Te, 77·4. Calc. for TeO_2: 79·9%). This material was used in the preliminary runs, but for the later work it was just fused and then allowed to crystallise, the central portions of the melt being used (Found: Te, 79·3%). Hydrogen chloride, dried and purified by passing successively through concentrated sulphuric acid and a cotton-wool filter, was led into a horizontal glass tube containing the dioxide (1—3 g.) in a porcelain boat at laboratory temperature. The oxide first turned yellow, then moist, and finally separated into yellow liquid and white solid layers; the solid lost 1·4% of moisture in a desiccator, but gained 12% on exposure to the air, dirty white friable solids being produced in each case. After various periods of passage of gas, the increase in weight of the contents of the boat

was irregular and neither the liquid nor the solid was of definite composition (see Table I).

TABLE I.

Run.	Time, hrs.	Increase in weight, %.	Empirical composition calc. from increase.	Liquid. Te %.	Liquid. Cl %.	Solid. Te %.	Solid. Cl %.
1	5	38·4	TeO_2,1·68HCl	30·7	29·0		
2	7	35·8	TeO_2,1·57HCl	30·6	26·1		
3	7	44·7	TeO_2,1·96HCl	—	—		

Further experiments were made with the oxide in a stoppered U-tube at laboratory temperature and at 100°. Pure, dry hydrogen chloride was passed first through a weighed stoppered U-tube (*A*) with a filling of phosphoric oxide, then through the reaction tube, and finally through a second, weighed, stoppered U-tube (*B*) filled in like manner. The drying-tubes were filled with hydrogen chloride before all weighings and the weight of the reaction tube was corrected for the change from air to hydrogen chloride. Baker (J., 1898, **73**, 422) has shown that unless phosphoric oxide is pure it absorbs small quantities of hydrogen chloride, and accordingly the difference between the increase in tubes *A* and *B* was taken as the amount of water leaving the reaction tube. Run 4 confirms Baker's observations, but in runs 5 and 6, carried out at 100°, it is obvious that the course of the reaction has changed; little hydrogen chloride has been absorbed, and some water, presumably that produced in the reaction, has been arrested by tube *B*. In these runs there was evidence of a slight reaction, the surface of the solid becoming greenish-yellow whilst a trace of brown sublimate was carried a little way up the limb of the reaction tube.

TABLE II.

Run.	Time, hrs.	Temp.	Weight of TeO_2, g.	Increase in weight, %.	Empirical composition calc. from increase.	Change in weight (g.) in *A*.	Change in weight (g.) in *B*.
4	5	18°	0·5564	40·4	TeO_2,1·77HCl	+0·0130	+0·0156
5	12	100	1·0420	6·3	TeO_2,0·27HCl	+0·0126	+0·0290
6	2·5	100	1·4154	9·3	TeO_2,0·41HCl	−0·0002	+0·0324

Three further runs (7, 8, 9) were carried out exactly as above in order to ascertain the change taking place in the material formed at 0° when it was subsequently heated in a stream of the gas. The reaction tube was first surrounded by a brine bath maintained at 0° ± 1° and gas was passed through the material for 5 hours. After the three U-tubes had been weighed the product was warmed to 100°, and subjected to the action of hydrogen chloride for a further 3 hours, and the tubes were re-weighed; finally, the temperature

was raised to 150°, and gas passed for a further 2 hours, after which the last weighings were made. The results are shown in Table III, from which it is clear that at the higher temperatures there is a loss of water and a nearly equal gain of chlorine.

TABLE III.

* Calculated from increase.

At the highest temperature, water carried forward by the gas stream was observed to condense in droplets in the connecting tubes. In run 10, which confirms the results in runs 7—9, drying tubes filled with calcium chloride were used to confirm the conclusion that the increase recorded in the *A* tube when phosphoric oxide was used is due to the cause indicated above.

Tellurium was estimated by dissolving weighed amounts of the compounds in hot concentrated hydrochloric acid and adding successively a saturated solution of sulphur dioxide, a 15% solution of hydrazine hydrate in hydrochloric acid, and finally more sulphurous acid; the resulting black colloidal tellurium was granulated by boiling for 10 minutes and then weighed on a Gooch crucible (compare Gutbier and Huber, *Z. anal. Chem.*, 1914, **53**, 430).

Selenium.—Crude dioxide was purified by solution in concentrated nitric acid, evaporation to dryness, and gentle ignition. Calcium chloride drying-tubes were used, and runs were conducted exactly as above at 0°, with change to 100°; at laboratory temperature, with change to 100°; and at 100° throughout. At 0° a very light yellow solid was produced which developed a considerable pressure of hydrogen chloride at the ordinary temperature, and there was no change in the weight of the *B* tube; on being heated to 100° this solid melted to a dark yellow liquid, and an increase was noted in the *B* tube, but it appeared to be due, not to water, but to the distilling forward of the undecomposed compound, for the tube became yellow, and, moreover, when the increase in weight of the *B* tube was added to the increase in the reaction tube, the sum always

indicated the presence of a substance having a composition very close to $SeO_2,2HCl$. At laboratory temperature a mixture of liquid and solid was produced which gave precisely similar results when heated to 100° in a current of hydrogen chloride. The product obtained directly at 100° behaved similarly. The results are given in Table IV.

UNIVERSITY OF DURHAM, ARMSTRONG COLLEGE,
NEWCASTLE-UPON-TYNE. [*Received, September 4th*, 1928.]

CCCLXXVII.—*The Production of Thiophen by the Interaction of Acetylene and Carbon Disulphide.*

By HENRY VINCENT AIRD BRISCOE, JOHN BUTTERY PEEL, and PERCY LUCOCK ROBINSON.

THE small proportion of thiophen that is formed, together with carbon disulphide, by the interaction of acetylene and sulphur vapour (Peel and Robinson, this vol., p. 2068) is produced probably by a direct reaction of acetylene with sulphur, and not by a secondary reaction between the gas and carbon disulphide, for the work described below indicates that thiophen is produced in quantity by the latter reaction only at temperatures considerably higher than those required when sulphur is used. The reaction of acetylene with carbon disulphide at 700° affords a convenient and cheap means of synthesising pure thiophen in quantity.

A rapid stream of acetylene, saturated with carbon disulphide vapour by passage through the boiling liquid, was delivered into the end of a horizontal silica tube (22 × 2 ins.), from which it passed through a water condenser to a collecting bottle. The tube could be maintained electrically at any desired temperature up to 800°, and the heated zone was packed with broken porous pot. Condensate from runs at specific temperatures was collected and separated

its constituents by the careful fractionation previously described, At 200°, the liquid was entirely unchanged carbon disulphide; a trace of thiophen appeared at 350° and the quantity gradually increased with rise of temperature until at about 700° the condensate contained approximately 10% by volume of thiophen and about 10% of hydrocarbons. This was the maximum yield for the particular length of hot zone used, nor was it possible to increase the yield by employing bauxite or granular copper sulphide as the furnace packing. At temperatures higher than 700° the tube became choked with carbon before the amount of condensate was sufficient for investigation.

Acknowledgment is made of a grant from the Research Fund Committee of Armstrong College, which enabled one of us (J. B. P.) to take part in this work.

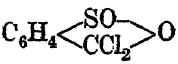
UNIVERSITY OF DURHAM, ARMSTRONG COLLEGE,
NEWCASTLE-UPON-TYNE. [*Received, September 4th*, 1928.]

CCCLXXVIII.—o-*Sulphinobenzoic Acid.*

By WILLIAM BENNETT PRICE and SAMUEL SMILES.

IN the course of experiments with hydroxy-derivatives of thioxanthone dioxide, *o*-sulphinobenzoic acid was required. Two methods are recorded for the preparation of this acid, either from *o*-diazobenzoic acid with sulphurous acid (Gattermann, *Ber.*, 1899, **32**, 1144) or from the dichloride of *o*-sulphobenzoic acid by reduction with alkaline sulphite (Davis and Smiles, J., 1910, **97**, 1290), but neither is suitable for the preparation of large quantities of the material, the yield being variable and the quality of the product, particularly when the latter method is used, often poor.

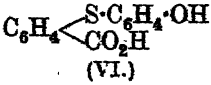
According to patent literature (D.R.-P. 35230), a solution of *o*-chlorothiolbenzoic acid is obtained when *o*-thiolbenzoic acid is treated with chlorine in presence of an inert solvent. No mention is made of the isolation of the chlorothiol, but assuming the formation of the substance, it was expected that on treatment with water the usual decomposition of chlorothiols observed by Zincke (for example, *Annalen*, 1918, **416**, 86) would ensue, yielding the sulphinic acid and the disulphide, the latter of which would be available for renewed treatment with chlorine. Accordingly, the action of chlorine on *o*-thiol- or *o*-dithio-benzoic acid in presence of carbon tetrachloride has now been more fully studied. As a result, although the *o*-chlorothiolbenzoic acid has not been encountered, good yields of an unstable *dichloro*-derivative have been obtained. This material,



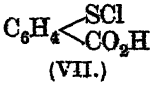
when carefully treated with water, yields the almost pure sulphinic acid. As described in the experimental part, a trustworthy and simple method for preparing the acid is thus available.

The reactions of this dichloro-derivative have been further studied with the object of determining its structure. The halogen is entirely and quickly removed by ice-cold water; *o*-sulphinobenzoic acid alone is formed, no disulphide being observed. In fact titration with alkali hydroxide accords with the equation

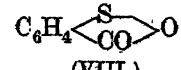
$$C_7H_4O_2Cl_2S + 4NaOH = 2NaCl + 2H_2O + CO_2Na{\cdot}C_6H_4{\cdot}SO_2Na.$$



The substance might accordingly be represented in any of the three following ways :



(I.)



(II.)

(III.)

but the acyl dichloride (I) and the *C*-dichloro-anhydride (II) structures are discarded for the following reasons. On treatment with *p*-nitrobenzyl alcohol a mononitrobenzyl ester was obtained together with *p*-nitrobenzyl chloride. The first-named product was evidently the *sulphinic ester* $CO_2H{\cdot}C_6H_4{\cdot}SO{\cdot}O{\cdot}CH_2{\cdot}C_6H_4{\cdot}NO_2$ (IV), since it yielded the sulphinic acid on hydrolysis and differed from the *sulphone*, $CO_2H{\cdot}C_6H_4{\cdot}SO_2{\cdot}CH_2{\cdot}C_6H_4{\cdot}NO_2$ (V), which was obtained from the sodium sulphinate and *p*-nitrobenzyl chloride or by oxidation of the corresponding sulphide. Moreover, the substance did not react with *p*-benzoquinone in the manner characteristic of sulphinic acids (Hinsberg, *Ber.*, 1894, **27**, 3259), and of *o*-sulphinobenzoic acid in particular. On treatment with phenols this chloro-compound yielded hydroxy-derivatives of *o*-carboxydiphenyl sulphide (*e.g.*, VI) together with chlorophenols. Neither with alcohols nor with phenols has any evidence of the formation of carboxylic esters been discovered. The incompatibility of this result with the structures (I) and (II) is evident and it is emphasised by the behaviour of the isomeric chlorides of *o*-sulphobenzoic acid with these reagents (List and Stein, *Ber.*, 1898, **31**, 1648). Moreover, the formation of the acyl dichloride (I) or of the *C*-dichloro-anhydride (II) by the action of chlorine on *o*-thiol- or *o*-dithio-benzoic acid cannot be simply interpreted. On the other hand, the formation of the *S*-dichloro-anhydride (III) by the process is readily explained by assuming the loss of hydrogen chloride from the *o*-chlorothiol (VII) and the sub-

(VI.)

(VII.)

(VIII.)

sequent addition of halogen to the sulphenic anhydride (VIII). For these reasons the substance is regarded as the *S*-di[illegible]

anhydride and it is evident that the reactions with *p*-nitrobenzyl alcohol and with phenols accord with this structure. Bearing in mind the tautomeric behaviour of the two chlorides of *o*-sulphobenzoic acid (List and Stein, *loc. cit.*), it seems not improbable that under suitable conditions conversion into the acyl dichloride might be realised, but as yet this has not been effected and no evidence of tautomeric character has been discovered.

During the investigation of the sulphinic ester (IV) and the isomeric sulphone (V) the p-*nitrobenzylsulphone ester* (IX) was encountered. This substance is attacked by alcoholic sodium hydroxide, yielding the red sodium salt of 3-*keto*-2-p-*nitrophenyl*-2 : 3-*dihydrothionaphthen dioxide* (X; R = $C_6H_4{\cdot}NO_2$). Further investigation of this method of synthesising 2-derivatives of thionaphthen dioxide is being made; from sodium *o*-sulphinobenzoate and ethyl chloroacetate, 3-keto-2-carbethoxy-2 : 3-dihydrothionaphthen dioxide (X; R = CO_2Et) has already been obtained. This product is identical

(IX.) $C_6H_4\begin{cases}SO_2{\cdot}CH_2{\cdot}C_6H_4{\cdot}NO_2\\CO{\cdot}O{\cdot}CH_2{\cdot}C_6H_4{\cdot}NO_2\end{cases}$ $C_6H_4\begin{cases}SO_2\\CO\end{cases}CHR$ (X.)

with the "anhydro" derivative obtained by Feist (*Ber.*, 1925, **58**, 2311) from the reaction of fuming sulphuric acid with ethyl benzoylacetate. The structure assigned to the substance by Arndt (*Ber.*, 1926, **59**, 1074), after examining the products of hydrolysis, is thus confirmed.

EXPERIMENTAL.

o-*Sulphinobenzoic Acid.*—Dry chlorine was passed into a mixture of dry carbon tetrachloride (40 c.c.) and *o*-thiolbenzoic acid (10 g.) until the latter had dissolved. Dry air or nitrogen was passed through the clear solution until hydrogen chloride and the excess of chlorine had been removed. The dichloro-anhydride, which separated in the crystalline state as a result of the fall in temperature and loss of solvent, was collected and spread on porous earthenware. Atmospheric moisture liberated hydrogen chloride from the material, and this decomposition was completed by means of ice. The sulphinic acid was then obtained in the crystalline state (yield, *ca.* 70%), the crude product having usually m. p. 123—124°. The purified acid decomposed and solidified a few degrees above its melting point (126°; Gattermann, *loc. cit.*, gives m. p. 125°), forming *o*-dithio- and *o*-sulpho-benzoic acids. With impure samples this decomposition may take place below the m. p., with the result that the material does not fuse until near the m. p. of *o*-dithiobenzoic acid (289°). This behaviour explains the high melting point recorded for the sulphinic acid by Davis and Smiles (*loc. cit.*), their product,

obtained by reduction of *o*-sulphobenzoyl dichloride, being evidently impure.

The *dichloride* (III) of *o*-sulphinobenzoic acid was prepared as described in the foregoing paragraph, purified materials being used. Owing to the instability of the substance and its sensitiveness to moisture. further purification by recrystallisation could not be effected. It formed cream-coloured needles, m. p. 62° (Found : Cl, 29·9; S, 14·3. $C_7H_4O_2Cl_2S$ requires Cl, 31·8; S, 14·3%. $C_7H_5O_2ClS$ requires Cl, 18·8; S, 17·0%). Decomposition with aqueous sodium hydroxide gave equiv., 56·0. $C_7H_4O_2Cl_2S$, according to the equation given on p. 2859, requires equiv., 55·7.

p-*Nitrobenzyl* o-*Carboxybenzenesulphinate* (IV).—A solution of the dichloride (from 4·25 g. of *o*-thiolbenzoic acid) from which excess of chlorine and hydrogen chloride had been removed was mixed with a concentrated solution of *p*-nitrobenzyl alcohol in dry ether. The *ester* separated in the crystalline state and after suitable purification from ether it was obtained in needles, m. p. 121° (Found : C, 52·4; H, 3·2; N, 4·4; S, 10·0. $C_{14}H_{11}O_6NS$ requires C, 52·3; H, 3·4; N, 4·3; S, 9·9%). *p*-Nitrobenzyl chloride was isolated from the mother-liquors of the reaction. The ester did not attack a cold aqueous suspension of *p*-benzoquinone. A sample was hydrolysed by boiling water; the products—*p*-nitrobenzyl alcohol and *o*-sulphinobenzoic acid—were isolated and identified in the usual manner.

o-*Carboxyphenyl*-p-*nitrobenzylsulphone* (V) was obtained by boiling the potassium salt of *o*-sulphinobenzoic acid (1 mol.) and *p*-nitrobenzyl bromide (1 mol.) in alcohol which contained a little water. The potassium salt of the required acid separated from the cooled mixture. The *acid* was purified from aqueous acetic acid; it had m. p. 226° and was not attacked by aqueous sodium hydroxide (Found : C, 52·3; H, 3·4; S, 10·0. $C_{14}H_{11}O_6NS$ requires C, 52·3; H, 3·4; S, 9·9%).

The p-*nitrobenzyl* ester (IX) of *o*-carboxyphenyl-*p*-nitrobenzylsulphone was obtained when a concentrated alcoholic solution of potassium *o*-sulphinobenzoate (1 mol.) and *p*-nitrobenzyl bromide (2 mols.) was boiled for 2 hours. After purification from acetic acid the product formed plates, m. p. 190° (Found : C, 55·6; H, 3·9; N, 6·4. $C_{21}H_{16}O_8N_2S$ requires C, 55·2; H, 3·5; N, 6·1%). This material was also obtained from the corresponding sulphide (Apitzsch, *Ber.*, 1913, **46**, 3098) by oxidation with hydrogen peroxide in acetic acid solution.

The p-*nitrobenzyl* ester of *m*-carboxyphenyl-*p*-nitrobenzylsulphone (compare IX) was prepared by a similar process and formed plates, m. p. 203° (Found : C, 55·4; H, 4·1; S, 7·0. $C_{21}H_{16}O_8N_2S$ requires C, 55·2; H, 3·5; S, 7·0%).

3-*Keto*-2-p-*nitrophenyl*-2 : 3-*dihydrothionaphthen* 1 : 1-*Dioxide* (X; R = $C_6H_4 \cdot NO_2$).—A solution of sodium (0·3 g.) in alcohol (75 c.c.) containing the sulphone ester (IX) (5 g.) was boiled for 2 hours. The red sodium derivative which separated from the cooled liquid was collected and treated with dilute sulphuric acid. The required *dioxide* was then obtained, after purification from acetic acid, in prisms, m. p. 186°. It was sparingly soluble in hot water, the solution being yellow (Found: C, 55·3; H, 3·4. $C_{14}H_9O_5NS$ requires C, 55·4; H, 3·0%).

3-*Keto*-2-*carbethoxy*-2 : 3-*dihydrothionaphthen* 1 : 1-*Dioxide* (X; R = CO_2Et).—A solution of ethyl chloroacetate (13·5 g.) and potassium *o*-sulphinobenzoate (14 g.) in alcohol (200 c.c.) and a little water was boiled for 2 hours, the precipitated potassium chloride removed, and a solution of sodium ethoxide (2·6 g.) added to the filtrate, which was then gently warmed. The yellow sodium derivative was collected and decomposed with dilute sulphuric acid. From the solution obtained, ether extracted the required substance, which was purified from alcohol and then found to be identical with the "anhydro"-compound of Feist (*loc. cit.*) (Found: C, 51·8; H, 4·0. Calc.: C, 51·9; H, 3·9%).

Hydroxy-derivatives of o-*Carboxydiphenyl Sulphide.*—A solution of the dichloride (III) was prepared by the action of chlorine on *o*-thiolbenzoic acid suspended in carbon tetrachloride (7 c.c. for every gram of the acid). After removal of free chlorine and hydrogen chloride, the usual precautions for the exclusion of moisture being taken, the solution was mixed with a phenol (2 mols.) in a suitable volume of carbon tetrachloride or dry ether. The required material had in most cases separated after 24 hours. The following products are typical of those obtained.

2-*Carboxy*-4'-*hydroxydiphenyl sulphide* (VI) formed small needles from acetic acid, m. p. 193° (Found: C, 63·3; H, 4·1; S, 12·8. $C_{13}H_{10}O_3S$ requires C, 63·4; H, 4·0; S, 13·0%). The structure assigned to the substance was shown by the conversion in warm sulphuric acid into 2-hydroxythioxanthone, the constitution of which has been determined by a method which will be subsequently described.

2-*Carboxy*-2' : 4'-*dihydroxydiphenyl sulphide*,

$$C_6H_3(OH)_2 \cdot S \cdot C_6H_4 \cdot CO_2H,$$

prepared from resorcinol, separated from hot water in needles, m. p. 190°, which assumed a yellow colour on exposure to light (Found: C, 59·7; H, 4·0; S, 12·1. $C_{13}H_{10}O_4S$ requires C, 59·5; H, 3·8; S, 12·2%).

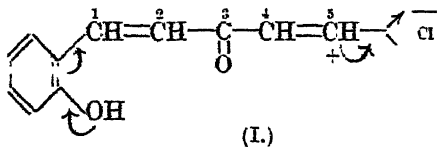
The interaction of the dichloride and resorcinol in equimolecular proportion under the conditions described gave *bis*-2'-*carboxy*-

phenylthiol-2 : 4-dihydroxybenzene, $C_6H_2(OH)_2(S{\cdot}C_6H_4{\cdot}CO_2H)_2$, which was obtained in small needles, m. p. 272°, soluble in hot alcohol and insoluble in water (Found : C, 57·9; H, 3·5. $C_{20}H_{14}O_6S_2$ requires C, 57·9; H, 3·3%).

o-Carboxyphenyl 2-hydroxy-α-naphthyl sulphide,

$$C_{10}H_6(OH){\cdot}S{\cdot}C_6H_4{\cdot}CO_2H,$$

prepared from β-naphthol, separated from alcohol in needles, m. p. 237°, which became yellow on exposure to light (Found : C, 68·9; H, 4·1. $C_{17}H_{12}O_3S$ requires C, 68·9; H, 4·0%).



The yields of the *o*-carboxyphenyl sulphides obtained from the process are generally good and the method thus leads to a convenient synthesis of hydroxythioxanthones. Examples of this application will be described in a future communication.

KING'S COLLEGE, LONDON. [*Received, October 10th*, 1928.]

CCCLXXIX.—*The Interaction of Ethyl Acetoacetate with Distyryl Ketones. Part IV. Selective Addition to Unsymmetrical Chlorodistyryl Ketones.*

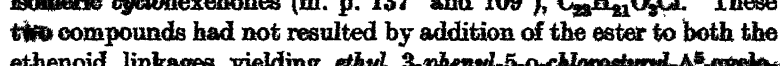
By ISIDOR MORRIS HEILBRON and ROWLAND HILL.

IT was shown in Part III (Heilbron and Hill, J., 1927, 918) that when ethyl acetoacetate was condensed with *o*-hydroxychlorodistyryl ketones, the ester invariably attached itself to the ethenoid linkage adjacent to the *o*-hydroxyl, irrespective of the position of the chlorine atom in the opposing styryl residue. These results were unexpected, as in ketones of this type the double bond vicinal to the chlorine-containing styryl residue must, if direct addition occurs, be the more reactive owing to the development of a positive charge at C_5 (I) due to the capacity of the chlorine atom to act as an attractor for electrons.

(I.)

The addition of ethyl acetoacetate to the three isomeric *monochlorodistyryl ketones* and also to 2 : 3′-, 2 : 4′-, and 3 : 4′-*dichlorodistyryl ketones* has now been studied in the hope of arriving at some general idea of the effect of the position of the halogen atom upon the activation of the ethenoid linkages in a series of compounds free from the possible disturbing influence of an ortho-hydroxyl group.

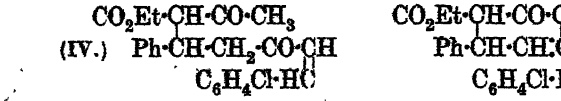
The preparation of the monochlorodistyryl ketones was a matter



of considerable difficulty owing to the ease with which styryl methyl ketone condensed with the chloroaldehydes, giving high-melting, amorphous polymerisation products in presence of alcoholic sodium ethoxide. The desired results were ultimately attained by employing very low concentrations of alkali, as recorded in the following table :

		Alkali concentration (NaOEt),				
					0·02—	
Ketone.	Aldehyde.	1—3 mols.	0·5 mol.	0·1 mol.	0·05 mol.	0·01 mol.
Methyl styryl ketone	*o*-Chlorobenzaldehyde	Amorphous solids	Oils	Oil	[illegible]	Aldol
,,	*m*- ,,	,,	,,	,,	,,	,,
,,	*p*- ,,	,,	Ketone	Aldol	Aldol	Aldol

In all cases the aldols could be quantitatively converted into the distyryl ketones on treatment with boiling acetic anhydride.

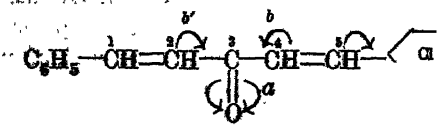


It was found impossible to obtain the dichlorodistyryl ketones by alkali condensations owing to the extraordinarily easy fission of the monochlorostyryl methyl ketones in presence of alkali. For instance, 2-chlorostyryl methyl ketone and *m*-chlorobenzaldehyde reacted in presence of 0·05 mol. of aqueous alkali, yielding, not the anticipated 2 : 3′-dichlorodistyryl ketone, but the symmetrical 2 : 2′-dichloro-isomeride, a reaction obviously due to fission of the reacting monostyryl ketone (compare Heilbron and Buck, J., 1921, **119**, 1500). The desired compounds were all obtained as crystalline halochromic salts by condensation in presence of dry hydrogen chloride at 0°.

The addition of ethyl acetoacetate to the distyryl ketones offered no special difficulties when the reactants were condensed in presence of alcoholic sodium ethoxide (0·1 mol.). The *cyclo*hexenones were readily obtained in crystalline form. Only one product was isolated in every case except 2-chlorodistyryl ketone, which gave two isomeric *cyclo*hexenones (m. p. 137° and 109°), $C_{23}H_{21}O_3Cl$. These two compounds had not resulted by addition of the ester to both the ethenoid linkages yielding *ethyl* 3-*phenyl*-5-*o*-*chlorostyryl*-Δ^5-*cyclohexen*-1-*one*-2-*carboxylate* (II) and ethyl 3-*o*-chlorophenyl-5-styryl-Δ^5-*cyclo*hexen-1-one-2-carboxylate (III), for on oxidation both

isomerides yielded *o*-chlorobenzoic acid without any trace of benzoic acid. The compounds may possibly be position isomerides. Of these, the higher-melting *cyclo*hexenone has probably the formula ascribed (II), since treatment of *ethyl* (*γ-keto-α-phenyl-ε-2-chlorophenyl-*Δ^δ-*pentenyl*)*methanoate* (IV) with sodium ethoxide readily

yields this product. On the other hand, the lower-melting isomeride, which is obtained only in poor yield, may be formed from the enolic form of (IV)—a reaction which is reminiscent of the coumalobenzopyran formation (Heilbron and Hill, *loc. cit.*); subsequent loss of water would then yield *ethyl* 3-*phenyl*-5-o-*chlorostyryl*-Δ^4-cyclo*hexen*-1-*one*-2-*carboxylate* (V). Alternatively, it is equally possible that the two compounds are stereoisomerides.



(IV.) (V.)

None of the *cyclo*hexenones described in this communication produces the blood-red coloration with concentrated sulphuric acid originally observed by Borsche (*Annalen*, 1910, **375**, 145) and considered indicative of *cyclo*hexenones of this type.

The constitutions of the *cyclo*hexenones were determined by oxidation with potassium permanganate in acetone solution (Heilbron and Hill, *loc. cit.*). Each mono-substituted *cyclo*hexenone yielded the corresponding chlorobenzoic acid, and the fact was thus established that, irrespective of the position of the chlorine atom, the ethyl acetoacetate enters the molecule at the ethenoid linkage vicinal to the non-substituted benzene nucleus. Provided the initial reaction consists in the *direct* addition of the negative ester ion to the unsaturated centre, these results are again wholly at variance with the electronic conceptions of reactivity which demand the formation of *cyclo*hexenones from which benzoic acid would be produced on oxidation.

It would thus seem that the mechanism of the reaction cannot consist in simple addition to a double bond. An alternative explanation, and one in harmony with the experimental results, can be found if the assumption is made that the activation of the ethenoid linkage is dependent upon the known tendency of the carbonyl oxygen atom to gain a negative charge. In such a case the following electronic conditions would obtain :

Process *a* is now the primary source of activation : process *b*, although secondary, is nevertheless essential. The latter effect may obviously be inhibited by the opposing general effect produced by the presence of the chlorine atom in the substituted styryl group, a condition which does not apply to process *b'*. As a consequence, addition of the ester would inevitably affect the ethen[illegible]

the unsubstituted styryl residue, as carbon atom C^1 now forms the terminal atom of the true "crotonoid" system (compare Allan, Oxford, Robinson, and Smith, J., 1926, 403).

The question of the addition to the dichlorodistyryl ketones is a complex one. Here the inhibitions of phases *b* and *b'* due to the strong general effect of the halogen atoms must become very nearly equal. Consequently, the negative ester ion will attach itself to either C^1 or C^5 according as the one or the other is more strongly influenced by the position of the chlorine atom in the respective aromatic nuclei. The actual effect is well illustrated in the case of the chlorobenzoic acids, where the order is $o>m>p$ as shown by their dissociation constants ($K = 0{\cdot}132$, $0{\cdot}0155$, and $0{\cdot}0093$, respectively). Exactly similar relationships apply to the *cyclo*hexenones. For instance, 2 : 3'-dichlorodistyryl ketone forms *ethyl* 3-o-*chlorophenyl*-5-m-*chlorostyryl*-Δ^5-cyclo*hexen*-1-*one*-2-*carboxylate*, from which *m*-chlorobenzoic acid is produced on oxidation. Similarly, the *cyclo*hexenones formed from both 2 : 4'- and 3 : 4'-dichlorodistyryl ketones yield *p*-chlorobenzoic acid.

EXPERIMENTAL.

2-Chloro-β-hydroxy-β-phenylethyl Styryl Ketone.—A solution of styryl methyl ketone (20 g.) and *o*-chlorobenzaldehyde (19 g.) in alcohol (150 c.c.) and water (100 c.c.) was treated with aqueous sodium hydroxide (5·5 c.c. of 1%: 0·01 mol.) and kept at 0° for several days. The yellow oil obtained, which solidified on vigorous scratching, formed long, colourless needles, m. p. 79—80° (yield, 11 g.), after repeated crystallisation from absolute alcohol. By liberally seeding the reaction mixture with the aldol as soon as the condensate commenced to separate, the yield was increased to 31 g. (Found: C, 71·4; H, 5·3. $C_{17}H_{15}O_2Cl$ requires C, 71·2; H, 5·3%).

2-Chlorodistyryl ketone may be prepared directly as described above by increasing the alkali concentration to 0·03 mol. (16·5 c.c. of a 1% solution). The separated pale yellow oil gradually formed a semi-solid mass (10 days), from which the aqueous layer was decanted. The residue was taken up in ether and, after removal of solvent from the dried extract, yellow crystals were obtained mixed with a viscous oil, which was removed by extraction with a small quantity of alcohol. The solid residue was crystallised repeatedly from absolute alcohol, from which the pure *ketone* separated in short yellow needles, m. p. 82—83°. Alternatively, the ketone can readily be prepared by refluxing the aldol for 2 hours with acetic anhydride (Found: C, 76·2: H, 5·1. $C_{17}H_{13}OCl$ requires C, 76·0; H, 4·9%).

3-*Chlorodistyryl ketone*, prepared in an exactly similar manner to the 2-chloro-isomeride, separated from alcohol in large plates, m. p. 108—109° (Found: C, 75·6; H, 4·8%).

4-*Chloro*-β-*hydroxy*-β-*phenylethyl Styryl Ketone*.—A solution of styryl methyl ketone (8 g.) and *p*-chlorobenzaldehyde (7·5 g.) in alcohol (80 c.c.) and water (60 c.c.) was treated with aqueous sodium hydroxide (8 c.c. of 1%) at room temperature. The yellow oil obtained, which solidified, was crystallised first from alcohol and finally from benzene, from which the *aldol* separated in colourless needles, m. p. 108—109° (Found: C, 71·2; H, 5·3%). On treatment of the aldol with acetic anhydride in the usual way, an excellent yield of 4-chlorodistyryl ketone was obtained, which crystallised from alcohol in glistening, pale yellow leaflets, m. p. 134°. The distyryl ketone may also be prepared directly from its constituents if the concentration of the alkali be increased to 0·5 mol. This substance has previously been obtained by Straus and Blankenhorn (*Annalen*, 1917, **415**, 256), but working under their conditions, we have only succeeded in isolating the aldol.

2 : 3′-*Dichlorodistyryl Ketone*.—2-Chlorostyryl methyl ketone (20 g.), prepared by Vorländer's method (*Annalen*, 1897, **294**, 291), and *m*-chlorobenzaldehyde (15·8 g.) were dissolved in dry ether (60 c.c.) and saturated with dry hydrogen chloride at 0°; heat was developed and the solution rapidly assumed a deep purple colour. After the mixture had been kept for 3 days in the ice-chest, the crystalline, red, halochromic salt was collected, washed with dry ether, and dissolved in boiling alcohol. The solution was then treated with sufficient sodium carbonate solution to discharge the red colour. After removal of precipitated inorganic matter, the yellow filtrate was diluted with water, and the precipitated *distyryl ketone* recrystallised from aqueous alcohol. It formed long yellow needles, m. p. 67—68°, sparingly soluble in light petroleum, ether, and carbon disulphide (Found: C, 67·1; H, 3·7. $C_{17}H_{12}OCl_2$ requires C, 67·3; H, 3·9%).

2 : 4′-*Dichlorodistyryl ketone* was prepared in a similar manner. It crystallised from alcohol in yellow needles, m. p. 109° (Found: C, 67·5; H, 4·0%).

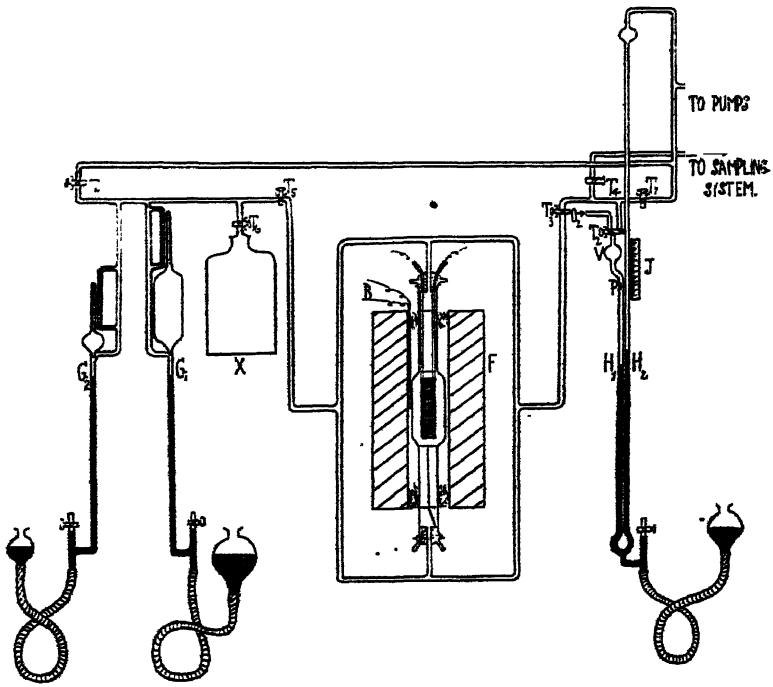
3-*Chlorostyryl Methyl Ketone*.—A solution of *m*-chlorobenzaldehyde (20 g.) in acetone (100 g.) was diluted with water to 2000 c.c. and then treated with aqueous sodium hydroxide (100 c.c. of 10%). The mixture was mechanically shaken for 48 hours, the separated oil extracted with ether, and the solution dried. After removal of solvent, the residual oil was distilled; the portion, b. p. 171°/20 mm., slowly crystallised at room temperature, forming yellow plates, m. p. 28—29° (yield, 17 g.). The *ketone* is readily soluble in the

Ethyl 3-m-*Chlorophenyl*-5-p-*chlorostyryl*-Δ^5-cyclo*hexen*-1-*one*-2-*carboxylate*.—3 : 4′-Dichlorodistyryl ketone (8 g.), dissolved in a minimum quantity of absolute alcohol (200 c.c.), and ethyl acetoacetate (5 g.) were refluxed for 15 minutes with sodium ethoxide (7·2 c.c. of a 1% solution). After concentration of the reaction mixture, yellow crystals were gradually deposited which were recrystallised from absolute alcohol. The purified cyclo*hexenone* separated in yellow prisms (6 g.), m. p. 122° (Found: C, 66·2; H, 5·1%), which dissolved in concentrated sulphuric acid to an orange-red solution. It is sparingly soluble in cold alcohol and carbon disulphide, readily soluble in acetone, benzene, and ethyl acetate. Oxidation gave *p*-chlorobenzoic acid, m. p. 236—238°, which was identified in the usual manner.

2 : 2′-*Dichlorodistyryl Ketone*.—2-Chlorostyryl methyl ketone (9 g.) and *m*-chlorobenzaldehyde (7 g.) were dissolved in alcohol (60 c.c.) and the solution was rendered just turbid by dilution with water. Aqueous sodium hydroxide (10 c.c. of a 1% solution) was added with vigorous shaking. The mobile yellow oil that separated was removed by extraction with ether and dried over anhydrous sodium sulphate. The oily residue left after removal of solvent was dissolved in ethyl acetate; crystals were then slowly deposited. The crude substance was recrystallised first from alcohol and finally from ethyl acetate, giving yellow needles, m. p. 124° (Found: C, 67·0; H, 4·1%), which were identified as 2 : 2′-dichlorodistyryl ketone by comparison with a specimen of the ketone prepared in the usual manner.

THE UNIVERSITY, LIVERPOOL. [*Received, August* 31*st*, 1928.]

CCCLXXX.—*The Heat of Adsorption of Oxygen on Charcoal. Part III.*



By DOUGLAS MCKIE.

ATTEMPTS are now described to refine the method of Blench and Garner (Part I; J., 1924, **125**, 1288) for determining the heat of adsorption of oxygen on charcoal under various conditions of temperature and pressure, and to extend it to the general case of the measurement of the heat of adsorption of a gas on a solid surface. So far, only one case, *viz.*, that of the adsorption of oxygen on charcoal, has been studied. The results obtained have already been summarised and their theoretical implications discussed in Part II (Garner and McKie, J., 1927, 2451).

Component Parts of Apparatus.—Reaction vessel. The reaction vessel is shown on a large scale in Fig. 2; it consisted of a tube of

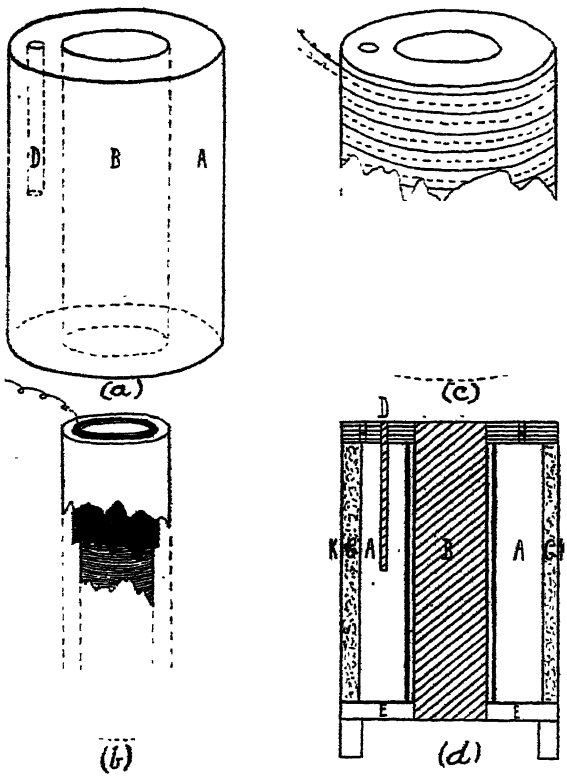
fused quartz, 40 cm. long and 2 cm. in diameter, open at both ends, the middle section being blown out in the form of a cylindrical bulb, A, 10 cm. long and 4·5 cm. in diameter. Hollow, closed stoppers, S_1 and S_2, of "Durosil" glass were ground to fit the open ends. A continuous and rapid current of cold water was passed through each stopper *via* the tubes, D D, to prevent undue heating of the rubber grease used to keep the ground joints vacuum-tight. The stoppers were further protected from the heat radiated along the tube of the furnace by means of fused quartz plates, R R,

FIG. 1.

arranged inside the vessel, two being placed on each side of the bulb, one just level with the shoulders of the latter and the other on a level with the end of the furnace. The upper two were attached to the wires carrying the container, K. The lower pair were joined as shown, one being fused to each end of a suitable length of quartz rod, and were supported on the lower stopper by a short limb of quartz, fused obliquely to the lower plate so as to rest clear of the tube passing through the stopper.

A tube was sealed through each stopper for the admission of gas, thus ensuring even distribution to each end of the bulb or

charcoal in K. Through the upper stopper there were also sealed two tubes for carrying the wires of the thermocouple, E, each wire being sealed into its tube at a distance of about 3 cm. from the stopper. In the fusion of the glass around the metal, the wires became brittle at this point, where there was always a tendency for them to be bent, and in order to prevent this bending, glass cups, C C, were fused on to the tubes carrying the wires. After the wires had been sealed into the leads just below the cups, the latter were filled with molten wax, which on solidification prevented any movement of the wires near the glass–metal joints.



The charcoal, about 5—6 g., was supported in the container, K, of 200-mesh platinum gauze, suspended by platinum wires from the glass hooks, N N, fused to the base of the stopper, S_1. The top of the container was closed by a platinum lid, bearing an insulating H-tube, Q Q, of fused quartz, carrying the wires of the thermocouple.

Furnace. The ordinary laboratory pattern of electrical furnace provided sufficient lagging for the reaction vessel to keep it at constant temperature during determinations at room temperature; in the experiments at higher temperatures, however, this furnace was not suitable, as its temperature could not be maintained sufficiently constant owing to variations in the voltage of the mains, and the furnace F was therefore designed. It consisted of a copper cylinder, A (Fig. 3*a*), about 27 kg. in weight, 25 cm. in length, and 15 cm. in diameter, cast with a central cylindrical bore, B, of 7·5 cm. diameter, which carried two concentric cylindrical quartz tubes of the same length as A. The inner of these had an internal diameter of 5 cm. and walls 0·1 cm. thick. Along its whole length, a coil of nichrome wire (20 S.W.G.) was closely wound and securely fastened at the ends. This tube was placed inside the outer tube, of external diameter 7·5 cm. and wall thickness 0·7 cm., and cemented into position by packing the annular space with alundum cement. The whole arrangement, shown in Fig. 3(*b*), was then passed into the bore of the copper cylinder, a thin layer of asbestos paper being placed between the copper and the quartz. The ends of the coil were connected *via* an adjustable series resistance with the 220-volt main. This coil was used to maintain the reaction vessel at 950° during the activation of

the charcoal. The reason for its special construction appears below.

The copper cylinder was wound on the outside with two subsidiary coils of nichrome ribbon, 0·1588 cm. by 0·0127 cm., each passing along its whole length, as shown in Fig. 3(*c*), and each having a resistance of about 45 ohms. Insulation between the copper and the coils was provided by a layer of asbestos paper.

FIG. 3.

The copper cylinder, etc., was then mounted on a fire-brick, E, 2·5 cm. high, in which a hole had been drilled of diameter equal to that of the bore of A, and placed in a rectangular tin, K, of cross-section 20 cm. by 20 cm. and height 30 cm., as shown in Fig. 3(*d*). The hollow portion, G, was packed with asbestos wool; H consists of asbestos boards with circular holes to correspond to the bores at the top of A.

The subsidiary heating coils were used during the determination of heats of adsorption at temperatures above atmospheric

means of them, the copper cylinder was heated to the temperature of experiment, both coils carrying current and being separately connected *via* adjustable series resistances with the 220-volt main. The temperature of the cylinder was controlled by means of a mercury-in-glass (hard) regulator, the bulb of which was placed in the hole, D, drilled in the copper, as shown in Fig. 3(*a*) and (*d*). This hole was 1·25 cm. in diameter and 12·5 cm. long, and the bulb of the regulator was constructed so as to fill it as exactly as possible. The regulator operated an electromagnetic relay, so arranged as to "break" the current through one of the subsidiary coils, if and when the temperature of the copper exceeded that desired. Thermal contact between the copper and the glass bulb of the regulator was improved by an intermediate film of B.P. paraffin. This system of regulation maintained the temperature constant to within $\pm$ 0·05° at 100° and $\pm$ 0·10° at 200°.

The purpose of the several coils will now be clear. The main coil was designed to carry 10 amps. and thus to provide rapid heating of the reaction vessel to the temperature of activation. The subsidiary coils carried currents of ½—1½ amps. Such currents gave small fluctuations of temperature in a furnace of so large a thermal capacity. The smaller current was always less than 1 amp., and was therefore such as to be easily broken by the relay. These subsidiary coils could not be used for activation at high temperature: heating was too slow, and the coils wore out under such drastic usage. Further, if the copper was heated to 950°, considerable oxidation occurred; hence the main coil was introduced for the preliminary activation. The lagging effect produced by the thick, outer, quartz tube was such that the temperature of the copper never rose beyond 600—700° during the two hours when the reaction vessel was at 950°, and oxidation was so slight that after months of use scaling was inappreciable. Further, the temperature of the reaction vessel could be raised from 18° to 950° in 10 minutes.

Pumping system. The pumping system consisted of a second-stage mercury-vapour diffusion pump, working under the backing pressure set up by a "Hyvac" rotary oil pump.

Sampling system. The sampling system consisted of a second-stage mercury-vapour diffusion pump in series with a Töpler pump, which allowed of the collection of a sample of gas from the reaction vessel after adsorption had taken place. The sample was collected in a capillary tube, where it was analysed as described below.

Gas burette. The gas burette, V (Fig. 1), was the one described in Part I (p. 1291), and the same procedure was followed.

Method of Recording Increments of Temperature.—Changes of temperature produced by adsorption were recorded by means of a

platinum–platinum-rhodium thermocouple, of which the "hot" junction, E, was embedded in the charcoal as shown in Fig. 2, the "cold" junction being maintained at a constant temperature (that of the furnace tube) either by insertion in a Dewar vessel containing water at room temperature in the experiments at that temperature, or by being placed inside the tube of the furnace close to the bulb of the reaction vessel in the experiments at higher temperatures. The thermocouple system was connected in series with a rigidly mounted Moll galvanometer, the mirror of which was illuminated by a 100 c.p. "Pointolite" lamp, enclosed in a light-tight box, and so arranged that an image of a slit as a fine vertical line of light was reflected from the mirror on to the cylindrical lens of a clock-work camera. This lens focussed the line to a point image, the movements of which were recorded on bromide paper, wound on a moving drum.

Calibration of Thermocouple.—The thermocouple was calibrated at 0° by means of two Dewar vessels, one containing crushed ice and water, and the other water at 3—4°. Calibration at 15° was carried out in the same manner by means of two samples of water at different temperatures near 15°. Similar calibrations were made at 60°, 100°, and 190° by means of a pair of baths at constant neighbouring temperatures. All temperatures were read on standard thermometers. The differential deflexions per degree were then plotted against the corresponding temperatures, and a smooth curve was drawn through the points obtained. From this the deflexion per degree difference of temperature could be read at any desired temperature.

Correction for the "Gas Effect."—The temperature–time curves obtained on the photographs were corrected for loss of heat by radiation as described later, but a further correction was necessary in the case of determinations at temperatures above atmospheric. This was due to the "gas effect," which has already been described in detail (Part I, pp. 1291—1292)—briefly, it is that rise of temperature which occurs on admission of any gas, whether adsorbed or inert, to the hot, evacuated reaction vessel. The phenomenon is largely due to the gradient of temperature inside the vessel between the walls of the latter and the thermocouple, this gradient being caused by convection currents in the reaction vessel. At very low pressures, heat is conducted away to the ends of the vessel by convection more rapidly than it is conducted inwards to E from the walls of A (Fig. 2).

This effect was allowed for as follows. Argon, purified as described later, was admitted to the reaction vessel from the gas burette in such amount that it gave in that vessel a pressure approximately

equal to that which obtained there after the adsorption of oxygen in the experiment to which the correction was to be applied. The rise of temperature occurring on admission of argon, *i.e.*, the "gas effect," was measured photographically as in the method previously described. The experiments showed that the temperature rose slowly, taking several minutes to attain its maximum, and then remained at a steady level, say, x units higher than the original temperature. It could be restored to that value only if and when the argon was removed by evacuation. The actual increment of temperature due to adsorption of oxygen was therefore taken to be the difference between x and the rise of temperature occurring when adsorption of oxygen took place. Similar experiments with argon were made at the various pressures and temperatures at which experiments with oxygen took place, and the corrections thus determined were applied to their respective experiments.

Complete Apparatus.—The assembled apparatus is shown in Fig. 1. On one side the reaction vessel was connected *via* tap T_5 with the bottle X (see below), and thence with the McLeod gauges, G_1 and G_2, which in turn were connected with the pumping system by means of the tap T_7; and on the other side it was connected with the pumping system *via* tap T_1. A further tap, T_3, was inserted between tap T_1 and the reaction vessel. Tap T_2 connected the reaction vessel with the gas burette. At a suitable point the sampling system was connected to the main apparatus by way of tap T_4. Save for the stoppers S_1 and S_2, the glass parts of the apparatus were of soft glass. Junction between the soft- and hard-glass parts of the apparatus was effected through ground joints, not shown in the diagrams.

Volume of the Apparatus.—The volume of the apparatus was determined by admitting a measured amount of oxygen from the gas burette to that part of the evacuated apparatus between taps T_1, T_4, and T_7, measuring the resulting pressure on the McLeod gauges, and then applying Boyle's law. The value obtained applied only to determinations at room temperature, because in the other experiments the reaction vessel was at a higher temperature, and the consequent thermal expansion of the gas led to an apparent decrease in the volume of the apparatus. To allow for this, the "apparent" or "equivalent" volume of the apparatus (see Part I, pp. 1291—1292) was determined by the method just described with the reaction vessel at various temperatures, carbon being absent.

Materials.—Oxygen was obtained by heating pure potassium permanganate and was dried by passage through phosphoric oxide.

The charcoal consisted of those particles of the vegetable charcoal, "Norit," which were sieved by the 100- and screened by the

150-mesh sieve. This portion was repeatedly boiled with hydrochloric and hydrofluoric acids to remove lime and silica, the ash content being thereby reduced from 7% to 0·3% and all traces of lime removed.

The argon was obtained from a sample containing about 5% of nitrogen and traces of oxygen and of the rare gases. For our purposes, this last impurity could be ignored. Nitrogen was removed by a modified form of the method of Rayleigh and Ramsay (*Phil. Trans.*, 1895, *A*, **186**, 197), the confining liquid being mercury instead of weak alkali. The author's thanks are due to Dr. M. W. Travers, F.R.S., who very kindly constructed the necessary apparatus, directed him in the technique of the process, and purified a large sample of the argon used. The nitrous gases formed were absorbed by a layer of aqueous caustic soda solution floating on the mercury. Excess of oxygen was subsequently removed by ignited phosphorus. Possible traces of phosphorus vapour were then condensed by cooling with solid carbon dioxide and alcohol. As a test of its purity, 1 c.c. (N.T.P.) of the argon was admitted at room temperature to 5 g. of charcoal previously activated at 950° in the usual manner. No measurable rise of temperature occurred, and the residual pressure indicated that only a negligible trace, if any, of the argon could have been adsorbed.

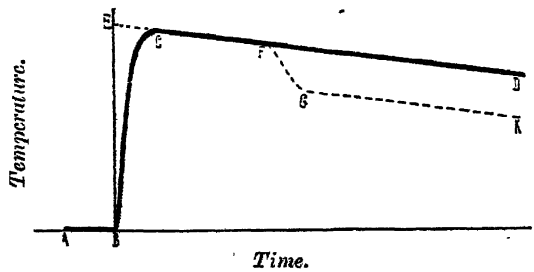
Method of Experiment.

This can best be followed by reference to Fig. 1. About 5—6 g. of the purified charcoal were heated in the reaction vessel by means of the furnace, F, for 2 hours at 950° under the high vacuum set up by the pumping system. During this time, the vacuum progressively improved to a steady value of 0·002 cm., below which it could not be reduced while the high temperature was maintained. The temperature of the furnace during this activation was recorded by means of a platinum–platinum-rhodium thermocouple, B, operating a sensitive millivoltmeter, giving direct readings of temperature. At the end of the 2 hours, the current through the furnace was cut off, but pumping was continued. As the temperature fell, the vacuum improved, and at 650° it was 1×10^{-4} mm. All taps, except T_6, were then closed.

When the furnace had cooled to the temperature of the experiment, suitable currents were passed through the subsidiary heating coils, and the thermoregulator was adjusted to give the temperature desired. When constancy of temperature had been obtained, or, if the experiment was at room temperature, when the furnace had cooled to that temperature, a measured amount of oxygen was admitted from the burette through tap T_2 to that section of the

leading tubes between taps T_1, T_3, and T_4, and confined there by closing tap T_2. The shutter of the camera was then opened, and one minute later the gas was admitted to the reaction vessel by opening tap T_3. After the lapse of another minute (test experiments having shown the maximum temperature to be reached within this time), tap T_5 was opened for 10 seconds for removal of a sample of the residual gas to that part of the apparatus between taps T_5 and T_7. The pressure of this gas was then read on the McLeod gauges. As indicated above, tap T_6 was open during this sampling; this tap connected the apparatus with the large bottle, X (of about $2\frac{1}{2}$ litres capacity), which was incorporated in the apparatus to remove from the reaction vessel as much as possible of the gas remaining after adsorption, preliminary experiments having shown that the initial rapid process of adsorption was followed by a much slower one, in which the oxygen was gradually taken up over a period of several days. This immediate removal of the bulk of the residual gas greatly reduced the pressure in the reaction vessel, and therefore either arrested further adsorption after the maximum temperature had been reached or reduced it to negligible proportions, thereby giving the true cooling curve and so permitting accurate correction for loss of heat by radiation.

When the temperature of the charcoal had fallen to its original value, the shutter of the camera was closed and the photographic record developed. At the same time taps T_4 and T_5 were opened, and the residual gas was removed by means of the Töpler pump for analysis. The apparatus was then evacuated to a pressure of 1×10^{-4} mm. without raising the temperature, after which a second admission of oxygen was made, and sometimes a third. After the last admission the charcoal was reactivated at 950° as before.



The sample of residual gas, collected *via* the Töpler pump in a capillary tube, was tested for carbon dioxide with an aqueous solution of caustic soda, for oxygen with alkaline pyrogallol, and for carbon monoxide with ammoniacal cuprous chloride. The various contractions were measured in the usual manner and the composition of the gas was calculated therefrom.

In the removal of the bulk of the residual gas to the bottle X and the McLeod gauges, the tap T_5 was opened for 10 seconds only. This interval of time was insufficient for the attainment of equal pressure throughout the apparatus, and therefore calibrations were made to find what equilibrium pressure corresponded to the pressure recorded by the gauges. The charcoal was removed from the apparatus, which was then evacuated to a pressure of 1×10^{-4} mm., after which taps T_1, T_4, T_5, and T_7 were closed. A measured sample of oxygen was admitted from the gas burette, and the same

procedure followed as in an actual experiment. After the pressure of the sample had been measured on the McLeod gauges, tap T_5 was opened. When equilibrium had been attained throughout the apparatus, the pressure was again read on the McLeod gauges. Varying amounts of oxygen were admitted in this manner so as to obtain figures covering the range of pressure of the experiments carried out. Values of the equilibrium pressure were then plotted against corresponding values of the observed pressure, and a smooth curve was drawn through the points obtained. From this curve the pressure corresponding to any observed pressure could be read, and from this value and the known volume of the apparatus the volume of gas unadsorbed was then calculated.

The volume of oxygen adsorbed by the charcoal was obtained by taking the difference between the volume admitted and that unadsorbed. Reduction of this volume to standard temperature

FIG. 4.

was made in the final calculation. The correction in the volume necessary in determinations of the heat of adsorption at temperatures higher than atmospheric has already been described.

The photographic curves obtained in these experiments were of the form shown in Fig. 4, in which ordinates represent intervals of temperature, and abscissæ intervals of time. The complete curve is represented by the thickened line, ABCD. During the interval of time from B to C, *i.e.*, the time taken to attain the maximum temperature, heat was being lost by the system through radiation, and to correct for this loss the line CD was produced backwards to cut the axis of temperature in the point E. The interval of temperature represented by BE was then taken to be the increment due to adsorption.

In the calculation of the heat evolved, this increment was multiplied by the thermal capacity of the materials undergoing that increment, *viz.*, the charcoal and the platinum container. The specific heats of platinum from 0° to 200° have been given by [illegible] (*J. Physical Chem.*, 1917, **21**, 345), who has also given similar

for graphite. As Weber (*Pogg. Ann.*, 1875, **154**, 557) has shown that the specific heat of wood charcoal over the range 0—225° exceeds that of graphite by the constant amount 0·003, the following values were used in calculating thermal capacities:

	Specific heat (g.-cals.).		
Temp.	Platinum.	Graphite.	Wood-charcoal.
0°	0·0310	0·156	0·159
50	0·0318	0·195	0·198
100	0·0323	0·233	0·236
200	0·0332	0·298	0·301

The heat due to the adsorption of oxygen, *i.e.*, the difference between the total heat liberated and that due to the production of oxides of carbon (determined from the analyses of gaseous products), was expressed as kg.-cals. per g.-mol. of oxygen adsorbed, the oxygen being corrected to standard temperature. No correction was necessary for deviations from Boyle's law.

In the experiments at temperatures above that of the room, correction was made for the "gas effect" by the method already described.

Results.

Heat of Adsorption of Oxygen on Charcoal at Room Temperature.—In Table I are the values obtained for the heat of adsorption of oxygen on charcoal at room temperature after activation at various temperatures from 750° to 950°, approximately the same amount of oxygen, about 1·5 c.c. (N.T.P.), being admitted in every case.

Mean molar heat of adsorption = 70 Cals.

Note.—The experiments were carried out in the order shown, *i.e.*, with intermediate activations at 950° to ascertain whether any decay in the activity of the charcoal had occurred. Mass of charcoal = 5·96 g. Mass of platinum = 6·665 g. All volumes are referred to normal pressure and room temperature.

Note.—The results tabulated here were obtained in two series of [illegible] in one of which 5·58 g. of charcoal were used, and in the other 5·6[illegible] mass of platinum = 6·665 g. All volumes are referred to normal pressure and room temperature.

In Table II are the values for the heat of adsorption of amounts of oxygen varying from 0·5 to 2·5 c.c. (N.T.P.), the temperature of activation throughout this series being 950°, this temperature having been shown by Rhead and Wheeler (J., 1913, **103**, 467) to be necessary for the removal of the oxygen adsorbed at lower temperatures. The results of Table II are summarised in Table III. In the column headed "Adm.," the figures i, ii, and iii indicate whether the admission of gas was a first, second, or third, respectively. In view of a result subsequently to be described, no correction was necessary for the heat developed by the formation of oxides of carbon at the temperature of these experiments.

A separate sample of charcoal was used for each series, and in the second series the charcoal was once replaced by a fresh sample: no difference was observed in the results obtained. The experiments of Table II were not performed in the order shown. The first experiments were made by admitting 1·5 c.c. of gas; after this, 2·0 c.c. and 2·5 c.c. were admitted, followed by several admissions each of 1·0, 0·5, 1·0, and 1·5 c.c.; then admissions of 1·5 c.c. alternated with 1·0 c.c., and, finally, the series closed with an admission of 0·5 c.c.

TABLE III.

Mean Values of the Heat of Adsorption at Room Temperature after Activation at 950°.

Approx. volume of oxygen admitted, c.c. at N.T.P.	Mean heat of adsorption, Cals./mol. (i.)	(ii.)	(iii.)
0·5	60	55	32
1·0	62	53	40
1·5	70	61	41
2·0	71	45	—
2·5	71	44	—

It will be observed from Table II that repeated adsorption of oxygen at room temperature, followed by repeated activation at 950°, appeared to have no destructive effect on the activity of the charcoal. After the standard activation, the same volume of oxygen was adsorbed and the same amount of heat was evolved even after 30 such admissions and activations. All these results were closely reproducible.

It was shown that no detectable amounts of oxygen were adsorbed on the quartz, glass, platinum, etc. (see p. 2886).

In the earlier experiments of Table II the sample of gas was taken off one minute after admission of oxygen, because this was known to be the time required for the rise of temperature to reach its maximum. It was, however, suspected that adsorption might be more rapid than the temperature–time curves suggested owing to

the lag involved in the thermometric method. The gas was therefore sampled at a much shorter interval after admission, first at 30, then at 20, at 15, and finally at 10 secs. The order of the residual pressure showed that, with negligible difference, the adsorption had progressed as far in 10 secs. as in 1 min. Other measurements showed that the adsorption of the residual gas was very slow, *e.g.*, whereas 1·125 c.c. were adsorbed in 10 secs., leaving a residue of 0·175 c.c., only 0·066 c.c. of the latter was adsorbed in 48 hours. There was therefore a sudden adsorption of the bulk of gas, followed by a very slow disappearance of the residue. This rapidity of adsorption of a gas on a solid surface is in accordance with theoretical prediction and is characteristic of true adsorption. It has been observed by other workers, *e.g.*, Angus Smith (*Proc. Roy Soc.*, 1862—3, **12**, 424; 1926, *A*, **112**, 296), in the case of oxygen on charcoal; McBain (*Phil. Mag.*, 1909, **18**, 918), for hydrogen on charcoal; and Lamb and Coolidge (*J. Amer. Chem. Soc.*, 1920, **42**, 1146), for various vapours adsorbed on charcoal. In the work of these authors, however, the time periods were of the order of a few minutes. Rhead and Wheeler (J., 1913, **103**, 469), in the case of oxygen on charcoal, observed a rapid disappearance of gas in the first 15 secs., followed by a much slower rate.

Attempts were made to desorb gas from the charcoal immediately after adsorption of oxygen. Such desorption would be indicated by a break in the continuity of the rearward slope, CD (Fig. 4), as shown by the broken line, FGK. For this purpose, the sampling system was employed, the procedure being as follows: A few minutes after maximum temperature had been reached, the tap T_4 was opened, and the reaction vessel rapidly evacuated. No break in the continuity of CD appeared. The adsorbed oxygen was therefore held so tenaciously by the charcoal that at room temperature it could not be removed under a vacuum of 1×10^{-4} mm.

The experiments of this series also showed that the time taken to attain maximum temperature in the case of first admissions varied with the amount of oxygen adsorbed. For admissions of 0·5 c.c. it was 2½ mins., for those of 1·0 c.c. it was 2 mins., and for those of 1·5, 2·0, and 2·5 c.c., 1 min. The corresponding times for second and third admissions were increasingly greater than those for first admissions, but this was doubtless due to the gradual decrease in the energy of the charcoal surface.

Some Experiments with Nitrogen.—Owing to a leak occurring during one of the experiments in the series just described, nitrogen was detected in the gas which was removed from the reaction vessel, and on this occasion a break appeared in CD (Fig. 4), the point corresponding to the time when the tap T_4 was opened, and

the dotted portion, FGK, of the curve was experimentally realised. It was subsequently found possible to reproduce this break at will by admitting mixtures of oxygen and nitrogen. When pure nitrogen was admitted, however, no such break appeared. Thus, at room temperature neither pure oxygen nor pure nitrogen could be desorbed, but some gas, which proved to be nitrogen, was desorbed after a mixture of oxygen and nitrogen had been admitted. Some of the data obtained are quoted below, all the adsorptions taking place at room temperature after activation at 950°, and all volumes being reduced to 760 mm. and room temperature.

(1) A first admission of 1·474 c.c. of nitrogen resulted in the adsorption of 0·293 c.c.; from a second admission of 1·545 c.c., 0·248 c.c. was adsorbed. The molar heat of adsorption was estimated at 38 and 19 Cals. respectively. In a third admission, of a mixture of 0·266 c.c. of nitrogen with 1·314 c.c. of oxygen, 1·028 c.c. of gas were adsorbed. A break appeared in CD.

(2) After reactivation, from 1·403 c.c. of nitrogen admitted, 0·223 c.c. was adsorbed with a molar heat of 46 Cals. In a second admission, of a mixture of 0·551 c.c. of nitrogen with 1·225 c.c. of oxygen, 1·152 c.c. of gas were adsorbed. A break was noted in CD.

(3) After reactivation, a mixture of 0·568 c.c. of nitrogen with 1·354 c.c. of oxygen was admitted. Of this, 1·284 c.c. were adsorbed. A break appeared in CD. In a second admission, of 1·567 c.c. of oxygen admitted, 0·436 c.c. was adsorbed. A break appeared in CD, which suggested that some of the oxygen adsorbed in the second admission had replaced the more firmly bound nitrogen, which pumping after the first admission had failed to desorb, and that this nitrogen could now be desorbed by pumping.

(4) After reactivation, 1·538 c.c. of oxygen were admitted, and 1·103 c.c. were adsorbed. Then 1·396 c.c. of nitrogen were admitted, and 0·265 c.c. was adsorbed. No break appeared in CD.

Consideration of the above data leads to the following comments on the respective experiments.

(1) After a total of 0·54 c.c. of nitrogen had been adsorbed, 1·028 c.c. of the mixed gases were still taken up, although the highly active fraction of the surface was already saturated with nitrogen.

(2) Although 0·223 c.c. of nitrogen had already been adsorbed, the charcoal still took up 1·152 c.c. of gas from the mixture of 0·551 c.c. of nitrogen and 1·225 c.c. of oxygen, which is more than would be expected in view of the previous admission of nitrogen.

(3) Similarly in this case, the adsorption of 1·284 c.c. is unexpectedly high.

(4) After adsorbing 1·103 c.c. of oxygen, the charcoal took up

even more nitrogen than in the case of the first admission in (2) above.

It therefore follows that (*a*) nitrogen, like oxygen, is adsorbed at once on a clean charcoal surface, either in first or second admissions, and cannot be removed therefrom at the temperature of adsorption; (*b*) when a mixture of oxygen and nitrogen is admitted, some gas can be pumped from the charcoal surface, irrespective of whether the mixture has been admitted to a clean surface or to one on which nitrogen has already been adsorbed; (*c*) gas can also be desorbed from the charcoal surface in the case of an admission of oxygen following an admission of a mixture of nitrogen and oxygen; (*d*) when nitrogen is adsorbed on a charcoal surface, on which oxygen has already been adsorbed, no gas can be pumped from the surface; and (*e*) the amount of gas adsorbed from a mixture of oxygen and nitrogen appears to be greater than would be expected from what is known of the separate adsorptions of these gases.

This phenomenon has not been thoroughly investigated, but the facts are sufficiently apparent. There is some change in the stability of the adsorption-complexes, formed on the surface of the charcoal, when the oxygen is diluted with nitrogen. This point has already been discussed in Part II.

Other workers have reported somewhat similar effects. De Saussure (*Ann. Physik*, 1814, **47**, 113) noted cases where the presence of a second gas increased the adsorption of a first, and detected the replacement of one gas by another. The latter effect was also observed by Angus Smith (*loc. cit.*).

Heat of Adsorption of very Small Amounts of Oxygen.—The results summarised in Table III indicated a decrease in the heat of adsorption with decrease in the amount of gas admitted. To test the possibility of this heat being still less for lower concentrations of gas, very small amounts of oxygen were admitted, and attempts made to determine their heats of adsorption. The experiments showed that at these low concentrations the oxygen was adsorbed completely without, as far as this apparatus indicated, any appreciable rise of temperature. A typical result may be quoted, all volumes being at normal pressure and room temperature. After activation at 950°, 0·036 c.c. was admitted at room temperature. When the gaseous contents of the reaction vessel were sampled according to the usual method, no increase in the pressure was recorded. The McLeod gauge still registered high vacuum. A second admission of an equal amount of gas gave the same result. A third admission of 0·089 c.c. and a fourth of 0·071 c.c. gave appreciable rises of temperature, with residues of unadsorbed gas of 0·001 and 0·003 c.c. respectively. Two further experiments

confirmed this result. The first minute quantities of oxygen were therefore adsorbed with a very low heat of adsorption, which was apparently less than 5 Cals./mol.

Immediately following these experiments with small quantities, and after re-evacuation, 1·5 c.c. of oxygen were admitted. In all cases the normal value was obtained for the heat of adsorption, and no reduction in the adsorptive capacity of the charcoal was apparent beyond that due to the amount of gas already adsorbed.

A test was made to determine whether the small amounts of oxygen had been removed by the platinum, quartz, etc. The charcoal was taken out of the apparatus and the process of activation carried out in its absence; 0·036 c.c. of oxygen was then admitted, and the volume of the apparatus was calculated from the resulting pressure as recorded by the McLeod gauges, but did not differ by more than the experimental error from the known volume, and thus showed that these small amounts of oxygen were adsorbed on the charcoal and not on any of the parts of the apparatus.

Heat of Adsorption of Oxygen on Charcoal from Room Temperature to 200°.—In Table IV are the values obtained for the heat of adsorption of oxygen on charcoal at various temperatures from room temperature to 200° after activation at 950° in each case. The same sample of charcoal was used throughout the experiments of this series: it was not so active as that used previously, *e.g.*, at 20°, of 3·0 c.c. (N.T.P.) of oxygen admitted, only 1·4 c.c. were adsorbed. The heat of adsorption had, however, the same value as that previously found for that temperature.

The increment of temperature recorded in the table is the net increment of temperature due to adsorption, *i.e.*, the difference between the (corrected) rise of temperature observed and that due to the "gas effect." The correction for the latter varied from 0·25° to 0·30°, *i.e.*, it was of the order of 10% approximately. The values given for the heat evolved are corrected for the heat of formation of the amounts of oxides of carbon found by analysis, except in the experiments at 60° and 100°, in which analyses were not made. This correction in the experiments at 150° and 200° amounted to 5% of the heat evolved. In Experiments 60 and 62 the residual pressure was not read until some minutes after adsorption had occurred, and in both these cases the tap T_5 was left open, not for 10 seconds as in the usual case, but for several minutes until a constant pressure was recorded by the McLeod gauges.

In these experiments it was found that at the higher temperatures the adsorption required about 1 min. for completion and therefore was not so rapid as at room temperature, where the adsorption

								Mean =	116

Note.—Mass of charcoal = 5·45 g. Mass of platinum = 6·665 g. All volumes are referred to normal pressure and room temperature.

here studied was complete in less than 10 secs. This may possibly be due to the blanketing effect of the oxides of carbon evolved.

Gaseous Products of the Adsorption of Oxygen on Charcoal.—The results of the analyses carried out in the experiments at 18°, 150°, and 200° were as follows:

Temp. of adsorption.	Gaseous products.
18°	Oxygen; trace of CO_2; no CO.
150	5% Oxygen; 95% CO_2; trace of CO (?).
200	9% Oxygen; 82% CO_2; 9% CO.

There was thus residual oxygen over the whole range of temperature of these experiments. Carbon dioxide increased up to 150°, and then decreased while the monoxide increased.

The "Active" Fraction of the Surface of Charcoal.—The "active" fraction of the surface of the charcoal used in these experiments may be estimated from the results of Table II. Its total surface was determined, from the isotherms of straight-chain alcohols adsorbed thereon (Garner, McKie, and Knight, *J. Physical Chem.*, 1927, **31**, 641), as 66 sq. m. per g. The volume occupied by an atom of carbon in charcoal is $1/D \div N/12$, where D is the density, and N the Avogadro number, $6{\cdot}062 \times 10^{23}$. On insertion of the value for D obtained by Cude and Hulett (*J. Amer. Chem. Soc.*, 1920, **42**, 391), *viz.*, 1·9, it is found that this volume is 1×10^{-23} [illegible]. If, as a first approximation, this space be assumed cubical, [illegible]

cross-sectional area corresponding to every atom of carbon is $4{\cdot}64 \times 10^{-16}$ cm.^{2}. The number of atoms on the surface of 1 g. of charcoal is, therefore, $66 \times 10^4/4{\cdot}64 \times 10^{-16} = 1{\cdot}4 \times 10^{21}$. The total number of atoms in 1 g. of charcoal $= N/12 = 5{\cdot}05 \times 10^{22}$. Therefore, the ratio of surface atoms to total atoms $= 1{\cdot}4 \times 10^{21}/5{\cdot}05 \times 10^{22}$, or 1 to 36.

Table II shows that at the most 2 c.c. (N.T.P.) of oxygen can be adsorbed by 5·6 g. of charcoal with a molar heat of adsorption of the order of 70 Cals. On the assumption that every molecule of oxygen is adsorbed on one atom of carbon only, and since the number of molecules in 1 c.c. (N.T.P.) of oxygen is $2{\cdot}7 \times 10^{19}$, the number of atoms per gram of charcoal giving a molar heat of adsorption of 70 Cals. $= 2 \times 2{\cdot}7 \times 10^{19}/5{\cdot}6 = 1{\cdot}0 \times 10^{19}$ (nearly). If these are regarded as active atoms, the ratio of active to total atoms is $1{\cdot}0 \times 10^{19}/5{\cdot}05 \times 10^{22}$, or 1 in 5000, and the ratio of active atoms to surface atoms is $1{\cdot}0 \times 10^{19}/1{\cdot}4 \times 10^{21}$, or 1 in 140.

This value for the active fraction of the surface is in qualitative agreement with the general results obtained by Langmuir, who found that these fractions were generally small, and that they increased with the temperature at which the surface was cleaned. Table I confirms this latter effect for the charcoal employed in this work, for it is there shown that the proportion of oxygen adsorbed at room temperature from a constant volume admitted increased steadily with the temperature of activation. The amount of gas adsorbed will depend, however, on two factors: (1) the temperature of activation, and (2) the efficiency of the process for removal of adsorbed gases.

The activity of the charcoal used in these experiments may be compared with that of the charcoal used by Keyes and Marshall (*J. Amer. Chem. Soc.*, 1927, **49**, 156). From the curve obtained by plotting the heat of adsorption against the surface concentration of oxygen, these authors calculated that the active surface of their charcoal was 5100 cm.^{2} per g. This value is in good agreement with that obtained in this work, *viz.*, 4700 cm.^{2} per g. Keyes and Marshall, however, concluded that, at the highest concentration at which they worked ($4{\cdot}5 \times 10^{-4}$ mol. per g.), many layers of gas were present. Their highest concentration is equivalent to $4{\cdot}5 \times 22400 \times 10^{-4}$ c.c. of oxygen per g. of charcoal, *i.e.*, 10 c.c. per g. From the value here recorded for the total surface area of 1 g. of charcoal, the number of molecules of oxygen necessary to form a unimolecular layer thereon is $.66 \times 10^4/\pi \times (1{\cdot}81 \times 10^{-8})^2$, since the radius of the oxygen molecule is 1·81 Å. (Jeans, "Dynamical Theory of Gases"); but the number of molecules in 1 c.c. (N.T.P.) is $2{\cdot}7 \times 10^{19}$, hence the volume of oxygen required to form a uni-

molecular layer = 24 c.c. per g. of charcoal, or more than twice the highest concentration measured by Keyes and Marshall. There is thus no evidence in their work of the formation of a second adsorbed layer, or even of the completion of a first layer. Moreover, their experiments did not indicate that their charcoal was saturated.

Summary.

A method is described for measuring the heats of adsorption of gases on solid surfaces, and is applied to the study of the adsorption of oxygen and of nitrogen on charcoal.

Details of a specially devised apparatus and furnace are given.

In conclusion, the author wishes to express his thanks to the Advisory Council of the Department of Scientific and Industrial Research for a maintenance grant, which enabled him to carry out the earlier part of this work, and to Prof. W. E. Garner for his constant help and direction during its progress.

THE SIR WILLIAM RAMSAY INORGANIC AND PHYSICAL CHEMISTRY LABORATORIES, UNIVERSITY COLLEGE, UNIVERSITY OF LONDON. [*Received, July 30th*, 1928.]

CCCLXXXI.—*The Ionisation of Aromatic Nitro-compounds in Liquid Ammonia. Part II.*

By WILLIAM EDWARD GARNER and HENRY FRANK GILLBE.

THE aromatic dinitro-compounds undergo ionisation in liquid ammonia at measurable speeds (Part I, Field, Garner, and Smith, J., 1925, **127**, 1227), giving rise to solutions the molecular conductivities of which are comparable in magnitude with those of typical electrolytes in this solvent. At moderately high dilutions, the ionisation is nearly complete. The rates of ionisation of the *m*-derivatives, as determined by conductivity measurements, are in agreement with the equation for reactions of the first order, whereas those of the *o*- and *p*-derivatives change in accordance with the equation for reactions of zero order. The *m*-compounds become faintly coloured immediately after solution, and blue or purple when the ionisation has reached its equilibrium value: the *o*- and *p*-derivatives are colourless initially and yellow or brown at the end of the ionisation. These colour changes are of interest in that they accompany changes in conductivity and hence may be due to the production of ions. If the ions only are coloured, then it should be possible by measurements of the extinction coefficients [illegible]

solutions to determine their concentration and to examine the relationship between ionic concentration and conductivity.

The absorption spectra of the *m*-dinitro-compounds show two bands, one in the yellow and one in the near ultra-violet, both increasing in width as the ionisation proceeds. In the case of the first band, this increase is due mainly to a movement of the less refracted edge. This is seen in photographs (Fig. 1) of the absorption spectra of solutions of *m*-dinitrobenzene taken at various times after the preparation of the solution. The neon spectrum photographed on the same plate provides a means of measuring the change in the width of the adsorption bands with time. A simple relationship holds between the wave-length of the edge of this band and the conductivity, *viz.*, $(\lambda_0 - \lambda_t)/\mu_t$ = constant, where λ_0 and λ_t are the wave-lengths (in Å.U.) of the edge of the band at the commencement of ionisation and at time t (in mins.), respectively, and μ_t is the product of specific conductivity (in mhos) and dilution at time t (see Table I). The dilution was in all cases 416·2 litres, and the values

of the specific conductivity are taken from the previous paper (*loc. cit.*).

The above relationship between the change in the wave-length of the edge of the absorption band and the conductivity is readily understood if both of these properties are directly proportional to the concentration of the ions. The movement of the edge of the band with change in concentration is not necessarily linear in character; the nature of the relationship depends on the type of photographic plate used and its sensitivity to light of different wave-lengths. The constancy of $(\lambda_0 - \lambda_t)/\mu_t$ is therefore very largely fortuitous. It does suggest, however, that both $\lambda_0 - \lambda_t$ and

FIG. 1.

Neon.

[*To face p.* 2890.]

μ_t are very possibly directly proportional to the concentration of a coloured ion. In order to settle this point definitely, it is necessary to make measurements of the extinction coefficients of monochromatic radiation passing through the solution. These have now been made at constant temperature (at or near $-35°$) for a number of wave-lengths with *m*-dinitrobenzene, and at one wave-length for 2 : 4-dinitrotoluene.

The extinction coefficient E may be defined by the equation $I/I_0 = e^{-Ecd}$, and if Beer's law be assumed to hold for these solutions, from one value of c and measurements of I/I_0 over a period of time, the change in concentration of the coloured substance can be followed. Such measurements are now described (see Experimental).

For this series of experiments, the concentrations of nitro-compounds were chosen in the region where ionisation is practically complete (94—96%), and hence the final ionic concentration will be the same as the initial concentration of the nitro-compound. The concentrations (c, in mols./l.) of the coloured substance calculated from this value and from measurements of I/I_0 are given in Table II. The ratio of conductivity l_t to c_t is constant. The conductivities of the solutions were measured between two platinum electrodes, and, in the case of 2 : 4-dinitrotoluene, simultaneously with the measurements of extinction coefficients. The cell constant was not

measured, hence the values for the conductivity are given in arbitrary units.

The concentration of the coloured substance as determined from the extinction coefficients is directly proportional to the conductivity of the solution at all stages during the process of ionisation. The colour of the solutions of *m*-dinitro-compounds is therefore due to the ions and not to any other substances formed during the ionisation; thus, the rate of production of the coloured ions in these compounds obeys the equation for reactions of the first order.

The ions present in these solutions were shown previously to be the nitro-compound in the form of an anion, and positively charged ammonia molecules as kations. Since the colour varies from one nitro-compound to another, the coloured ion must be the anion.

Nature of the Ionisation in Solutions of Nitro-compounds in Liquid Ammonia.

The majority of substances dissolved by liquid ammonia obey the law of mass action in their ionisation much better than those in aqueous solutions. The law of mass action holds fairly accurately for dilute solutions of liquid ammonia (Kraus, "Properties of Electrically Conducting Systems," p. 56). On applying the equations $K_1 = \alpha^2/v(1-\alpha)$ and $K_2 = \alpha^3/v^2(1-\alpha)$ to Franklin's values of the molecular conductivity of *m*-dinitrobenzene in liquid ammonia, it is found that K_1 gives a much better constant than K_2 (Table III).

43·30	71·5	0·0036	0·27	752·0	156·4	0·0023	0·02
95·40	90·2	0·0030	0·13	1485·0	179·9	0·0024	0·01

The dissociation constant K_1 is very similar to that of typical binary salts in ammonia; *e.g.*, for ammonium chloride, $K = 0{\cdot}0016$; for potassium bromide, $K = 0{\cdot}0022$; and for potassium nitrate, $K = 0{\cdot}0017$ (Franklin and Kraus, *Amer. Chem. J.*, 1900, **23**, 298). The evidence is thus in favour of the view that the ionisation of dinitro-compounds in liquid ammonia is of a binary character.

It was shown previously that one of the ions was in all probability NH_3^{++} (or $N_2H_6^{++}$), since no trace of any substance was detectable at the cathode either during or after electrolysis of a solution of *m*-dinitrobenzene in ammonia. Hence it was suggested that the ionisation process was

$$R(NO_2)_2 + NH_3 \overset{(I)}{\rightleftharpoons} R(NO_2)_2,NH_3 \overset{(II)}{\rightleftharpoons} R(NO_2)_2^{--} + NH_3^{++} \quad (1)$$

On the basis of the Lewis–Langmuir octet theory, it is more probable that the ammonia ion is $N_2H_6^{++}$, and that the equation should be

$$R(NO_2)_2 + 2NH_3 \overset{(I)}{\rightleftharpoons} R(NO_2)_2,2NH_3 \overset{(II)}{\rightleftharpoons} R(NO_2)_2^{--} + N_2H_6^{++} \quad (2)$$

Attempts were made to prepare the intermediate compound, $R(NO_2)_2,2NH_3$, which might be stable in the solid state. A vapour-pressure method was used at temperatures in the neighbourhood of −40°, but no evidence was obtained for the existence of such a compound. It is, however, necessary to assume the formation of an intermediate compound during the ionisation process, otherwise it is impossible to explain the fact that the rate of ionisation of 2 : 6-dinitrotoluene, which is only ionised to the extent of about 2% at 400 litres, obeys the first-order law. Equation (3) is therefore unlikely :

$$R(NO_2)_2 + 2NH_3 \rightleftharpoons R(NO_2)_2^{--} + N_2H_6^{++} \quad . \quad (3)$$

If this equation represented the course of the reaction, the occurrence of the preponderating reverse reaction would prevent a constant being obtained for the equation $k = 1/t \,.\, \log_e a/(a - x)$.

This applies to a less degree also to the other dinitro-compounds, which are not completely ionised at dilutions of 400 litres (compare Part I, *loc. cit.*). Thus, we are driven to the conclusion that the stage in the reaction which determines the order is not the ionisation process, and therefore we postulate the formation of an intermediate compound [stage (I), reaction (2)].* Whatever the nature of this reaction, since it obeys the first-order law, it must go to completion.

In the previous paper, the equation

$$k = 1/t \,.\, \log_e \mu_e/(\mu_e - \mu_t) \quad . \quad . \quad . \quad . \quad . \quad (4)$$

where μ_e and μ_t are the molecular conductivities of the solutions at the end of the reaction and at a time t, respectively, was applied to the changes in conductivity in solutions of nitro-compounds. This equation is only strictly accurate, when applied to reaction (2), if the dilutions are such that the ionisation is complete. When the ionisation is incomplete, the conductivity is no longer an exact measure of the amount of intermediate compound produced, and equation (4) requires modification. If α_e and α_t represent the degrees of ionisation at equilibrium and at a time t, respectively, then the equation

$$k = \frac{1}{t} \log_e \frac{\mu_e/\alpha_e}{\mu_e/\alpha_e - \mu_t/\alpha_t} \quad . \quad . \quad . \quad . \quad . \quad (5)$$

* The critical increment of the reaction, which is found to be 7,520 cals., is that corresponding to chemical change rather than to an ionisation process, for which a much larger value is probable.

would be expected to be more nearly correct than equation (4). The values of α may be obtained from the specific conductivities of Franklin by plotting κ against α. Table IV shows the effect of applying equation (5) to the velocity measurements for *m*-dinitrobenzene.

TABLE IV.

t.	μ.	κ.	α.	μ/α.	k.	k (Part I).
10	84·3	0·404	0·556	152	0·107	0·140
12	89·4	0·429	0·542	165	0·105	0·133
16	98·3	0·471	0·520	189	0·109	0·131
22	106·0	0·508	0·500	212	0·114	0·133
10	96·8	0·232	0·687	141	0·109	0·132
13	109	0·262	0·660	165	0·116	0·134
17	118	0·283	0·645	183	0·115	0·132
22	123	0·296	0·635	194	0·112	0·134
24	126	0·302	0·630	200	0·117	0·129

For those nitro-compounds which are ionised considerably in liquid ammonia, the use of equation (5) does not improve the constancy of k. There is, however, an appreciable source of error in interpolating from Franklin's results. In the case of 2 : 6-dinitrobenzene, where the ionisation is much less complete, there is a marked improvement in constancy. To make this calculation, it is assumed that the conductivity at infinite dilution is the same for 2 : 6-dinitrotoluene as for *m*-dinitrobenzene. Such an assumption is justifiable, since the introduction of a methyl group into a heavy aromatic molecule would have but little effect on the mobility of the anion. The following results are thus obtained:

t	11	54	108	162
k	0·015	0·015	0·014	0·015
k (Part I)	0·028	0·021	0·017	0·015

The very feebly ionised 2 : 6-dinitrotoluene gives a good constant when k is calculated from equation (5). The assumptions made above with respect to the mechanism of the ionisation process have been justified by all of the facts at our disposal.

The values of k calculated from the measurements at higher dilutions, $v = 4000$, where α does not change appreciably during the reaction, agree within experimental error (see results for 2 : 4-dinitrotoluene, Table VII).

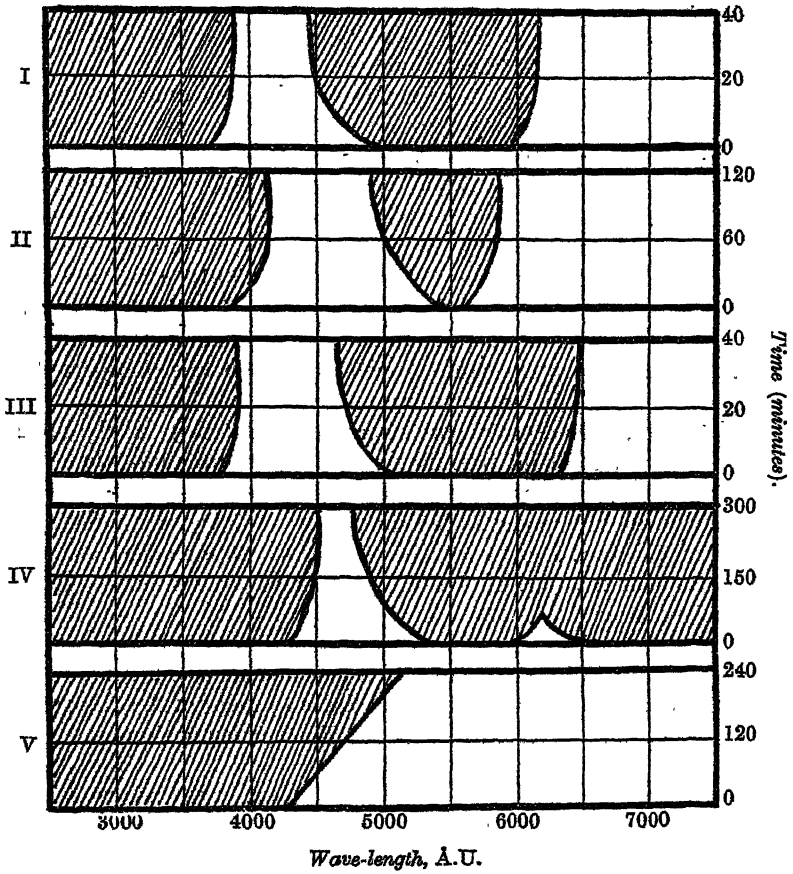
Thus equation (2) represents in a satisfactory manner the course of the reaction. The first stage is a slow reaction which goes to completion, and the second stage is rapid and proceeds to equilibrium. At moderate concentrations, the ionisation is not complete. The characteristic colour of these solutions is due to the anion, which is very probably $R(NO_2)_2^{--}$. There is a direct proportionality between the conductivity of the solutions and the concentration of the anion at any time during the course of the reaction.

EXPERIMENTAL.

Preliminary Absorption Measurements.—A simple form of apparatus was used consisting of a light-tight wooden box with a tightly fitting lid; at one end was fixed a 250-c.p. Pointolite lamp, and at the other an unsilvered Dewar vessel of about 280 c.c. capacity, which could be wedged tightly against a hole of about 2 cm. diameter at the end of the box. The light passing through the Dewar vessel fell on the slit of a Hilger constant-deviation spectrometer.

The Dewar vessel was nearly filled with liquid ammonia, and a known amount of nitro-compound added, either as a solid or in solution in 1 or 2 c.c. of ethyl alcohol. Photographs were taken after varying intervals of time on the same plate (Fig. 1). The addition of the nitro-compounds in solution ensured a greater rapidity of admixture, and the presence of a small quantity of alcohol did not affect the rate of ionisation. With the slit at 0·15 mm., and with Ilford Panchromatic plates, an exposure of ½—1 minute was found to be ample for the dilutions used. For ease in determining the edges of the absorption bands, a neon spectrum was photographed above and usually below each series of spectra.

Although the plates were panchromatic, the intensity of the image obtained with the light passing through liquid ammonia alone was not quite uniform from one end of the spectrum to the other, especially in the green. The image was, however, sufficiently uniform for the purpose of the above measurements, since the movement of the edge of the bands occurred over a narrow region of the spectrum.



Experiments were made with *m*-dinitrobenzene and 2 : 4-, 2 : 6-, 3 : 5-, and 3 : 4-dinitrotoluenes at a dilution of 416·2 litres. The position of the absorption bands and the movement of the absorption edges with time are given in Fig. 2. The shaded regions show the absorption bands.

One or two points of interest emerge from the spectrum–time diagrams (Fig. 2). All the *m*-dinitrotoluenes and *m*-dinitrobenzene show absorption bands at about 3000—4000 Å. In all cases the bands widen with time. The introduction of a methyl group in the meta-position to two nitro-groups (I and III) has hardly any effect either on the position or on the velocity of movement of the edge of the bands. If this group is ortho to one of the nitro-groups (IV), the band in the yellow narrows; and if it is ortho to two nitro-groups (II), the band is narrower still. Nitro-groups ortho or meta to a methyl group have but little effect on the position of the ultra-violet band, whereas the introduction of a *p*-nitro-group (IV) moves this edge towards the red and also causes the appearance of an

absorption band in the extreme red. The absorption edge of 3 : 4-dinitrotoluene moves linearly with time.

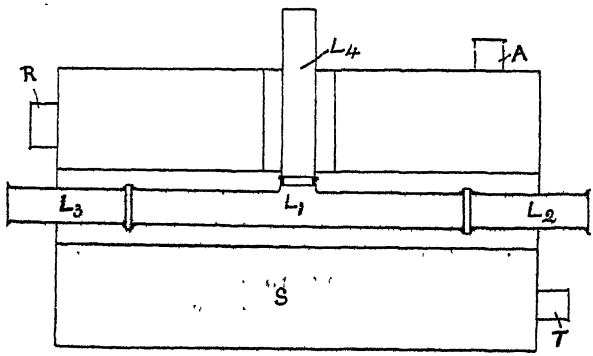
Molecular Compounds.—It was considered possible that compounds of the type $R(NO_2)_2,xNH_3$ might be stable in the solid state, especially as the solids separating on evaporation of the ammonia solutions

FIG. 2.

I. m-*Dinitrobenzene.* II. 2 : 6-*Dinitrotoluene.* III. 3 : 5-*Dinitrotoluene.* IV. 2 : 4-*Dinitrotoluene.* V. 3 : 4-*Dinitrotoluene.*

appeared to be coloured. Vapour-pressure measurements made on solutions of both the *m*- and the *o*- and *p*-derivatives during the process of evaporation failed to yield any evidence of the occurrence of such compounds in the solid state. A range of temperatures down to −48° was covered.

Critical Increment of Reaction.—From conductivity measurements of solutions of *m*-dinitrobenzene in liquid ammonia over a range of



temperatures, the critical increment of the reaction was shown to be 7,520 cal. The corresponding velocity coefficients were :

Temp.	− 34·4°	− 39·3°	− 41·3°	− 44·5°
k	0·176	0·133	0·116	0·087

The wave-length corresponding to the energy of activation lies in the infra-red at 3·78 μ. The change was not accelerated by the light from a mercury-vapour lamp.

Measurement of Extinction Coefficients.—To make measurements of extinction coefficients, it was necessary to enclose a known volume of solution in a vessel maintained at constant temperature and having optically worked windows at a known distance apart. The final form of the apparatus is shown in Fig. 3. The constant-temperature bath consisted of a welded, mild-steel tank, S, measuring about 6″ × 4″ × 4″, filled with commercial ammonia; R is an

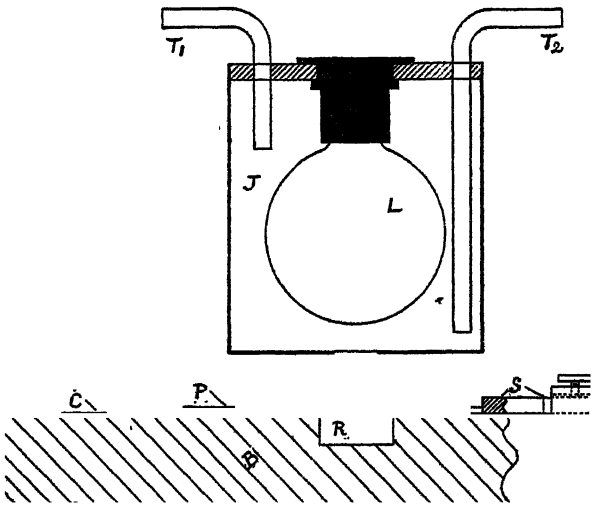
FIG. 3.

opening for a temperature regulator and air vent, T an opening for an alcohol thermometer, and A the air inlet. The temperature was controlled by regulating a stream of air, bubbling through the ammonia, by means of a relay and magnetic cut-off. The thermostat was heavily lagged with felt.

The reaction vessel consisted of four parts, L_4 fitting into L_1 by means of a ground joint, and the end portions L_2 and L_3 being attached to L_1 by means of guttapercha and separated by polarimeter plates. L_2 and L_3 projected some distance beyond the ends of the tank and their end plates prevented condensation of water vapour on the ends of L_1 during the measurements. Guttapercha was found to be the only suitable cement at −35° for attaching the polarimeter plates; other adhesives either cracked at the temperature or were attacked by liquid ammonia.

The tank was placed in position between a Hilger deviation spectrograph and a light-tight wooden box

a Pointolite lamp and a condensing lens system. The current through the lamp was maintained constant to 1 part in 500 parts. The width of slit found to be most satisfactory was 0·15 mm.



The experimental procedure was as follows: (1) The tank was filled with commercial ammonia and the temperature adjusted to the required value. (2) The reaction tube was filled with pure ammonia. (3) A trial exposure was made in order to ensure that there was even illumination along the length of the collimator slit: it was impossible to determine this visually. (4) A series of photographs was taken with exposures varying from 5 seconds to 1 minute of that part of the spectrum at which it was intended to make measurements, with a neon spectrum above and below the series. During this operation the rest of the plate was screened with a thin piece of cardboard. (5) The dark slide was moved a certain distance horizontally, and the card screen removed. (6) A known volume of an alcoholic solution of the dinitro-compound under investigation was added to the reaction tube and the volume made up immediately to a mark on the vertical tube, L_4. At this moment a stop-watch was started, and the first exposure made as soon as possible. A series of photographs was then taken over the whole period of the reaction—about 30 minutes in the case of *m*-dinitrobenzene—an exposure of 1 minute being given in each case. As only 6 or 7 photographs could be taken on one plate, the earlier ones were taken at shorter intervals than those at the end of the reaction, since at the beginning the spectrum was changing most rapidly. Photographs were therefore taken at about 2, 5, 9, 14, 19, 24, and 30 minutes from the commencement of the reaction. (7) Photographs of the neon spectrum were taken immediately above and below the reaction exposures.

It was intended to make simultaneous measurements of the conductivities of the solutions, but owing to the short time taken for the reaction to go to completion, this was not always possible. The final experiments were made with 2 : 4-dinitrotoluene, which takes some 5—6 hours to attain equilibrium. In this instance, conductivity measurements could without difficulty be made simultaneously with the photographs of the absorption spectra. In other cases, conductivity measurements were made separately.

Measurement of the Plates.—The densities of the photographic images were measured by means of a thermopile connected to a Moll galvanometer with the usual lamp and scale. The apparatus constructed for this purpose is shown in Fig. 4. The thermopile (not shown) was fixed rigidly in the recess, *R*, in the wooden block, *B*, the leads being taken out through the sides of the block. Attached to the surface of the block was a sheet of blackened card, *C*, having a

slit immediately above the thermopile element about 1 mm. wide and somewhat shorter than the width of one of the spectral images on the photographic plate. At a short distance above the slit was clamped a "Fullolite" lamp, L, surrounded by a blackened glass tank, J, having a clear circle at the bottom. A rapid stream of water at constant temperature could be circulated through the tank *via* the tubes T_1 and T_2. This ensured the removal of infra-red radiation from the beam which reached the thermopile; errors would otherwise have been introduced by the gradual heating of the apparatus, and by variations in the thickness of the glass plate, since glass shows marked absorption in the infra-red.

FIG. 4.

It was necessary to ensure that the same wave-length band would be measured for each of the spectra of a series, *i.e.*, that the movement of the plate necessary to bring successive spectra of a series over the slit was in a direction at right angles to the length of the spectra. This was accomplished by preparing a number of steel strips with accurately parallel edges and of known width, from about $\frac{1}{8}''$ to $2''$ wide. A steel straight edge was clamped to the block B in such a position that when the plate to be measured was moved with one edge always in contact with the straight edge, corresponding lines in the two neon spectra could be superimposed in succession on the slit above the thermopile element. Measurements of the spectral images at the wave-length of this line could thus be carried out. By placing between the straight edge and the edge of the plate one or more of the steel strips, further series of measurements

wave-lengths could be made. In the figure, two of the steel strips are shown held in position by the clamp, *V*. *P* represents a plate in position for measurement.

Knowing the rate of change of wave-length along the neon spectrum, together with the width of the steel strips used, the wave-lengths at which the measurements had been made could be calculated. Measurements were made at the same wave-lengths for the calibration exposures as for the exposures made during the reaction. In all cases the galvanometer deflexions were taken as the plate was moved backwards and forwards above the slit.

Having measured the densities of the images given by the calibration exposures and by the "reaction exposures" (at the same wave-lengths), one can calculate the fraction of light transmitted through the solution at any time. In the calculation which follows, it is assumed that the density of the image is directly proportional to the total quantity of light energy falling on the plate, an assumption which, although not rigidly true, is approximately so over a certain range of exposures [compare Baly, *Proc. Roy. Soc.*, 1927, *A*, **113**, 711, for a critical investigation of the Schwarzschild equation, $D = kIT^n$; the statement is there made that the results "would seem definitely to establish that the Schwarzschild exponent (n) is unity"]. In all the measurements with *m*-dinitrobenzene, the calibration curves obtained by plotting time of exposure against galvanometer deflexion are straight lines over the range employed in the further calculation.

In Table V are given the calibration figures for Plates I and II, for *m*-dinitrobenzene; *T* is the time of exposure in seconds, and under the various wave-lengths are given the galvanometer deflexions for each image. *A* is the intercept of the calibration line on the deflexion axis, and $b/60$ the slope of the line (in secs./cm.) divided by 60, a quantity which is required in the subsequent calculation of the extinction coefficients.

TABLE V.

	Plate I.				Plate II.

25	92	100	6	125	194	126	80
30	76	84	4	111	180	114	61
35	60	74	3	106	166	109	47
40	—	—	—	—	162	106	32
A =	188	196	62	230	296	220	162
$b/60 \times 10^6$ =	4387	4387	6945	3970	4167	4386	5051

Let D = density of image, I = intensity of light falling on the photographic plate, and d = galvanometer deflexion due to the image. Then, for the calibration exposures

$$D_n = kT_nI_0 = k'(A - d_n) \quad . \quad . \quad . \quad . \quad . \quad (6)$$

since on plotting T against d for the calibration exposures a straight line is obtained; n refers to the number of seconds. In this case I_0 is constant and T variable.

For the "reaction exposures" $D_t = kT_0I_t$, where T_0 is constant (= 60 secs.), and I_t, the intensity of light transmitted by the solution at time t, varies as the reaction proceeds. Further, we may write

$$D_t = k'(A - d_t) \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (7)$$

where A is the deflexion for the plate when exposed to light of zero intensity, and is necessarily the same as in equation (6).

The quantity required is I_t/I_0, the fraction of the incident light transmitted through the solution at time t. From equations (6) and (7)

$$\frac{I_t}{I_0} = \frac{(A - d_t)T_n}{(A - d_n)T_0} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (8)$$

But $T_n/(A - d_n)$ is the slope of the line obtained by plotting T against d for the calibration exposures, in sec./cm. Putting this equal to b, and substituting for $T_0 = 60$ secs., we have

$$I_t/I_0 = b(A - d_t)/60 \quad . \quad . \quad . \quad . \quad . \quad . \quad (9)$$

The extinction coefficient is defined by E in the equation

$$I = I_0e^{-Ecd'} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (10)$$

where I/I_0 is the fraction of light transmitted through a layer of solution of thickness d' and concentration c.

If it be assumed that the reaction between the dinitro-compound and ammonia goes to completion, the concentration at equilibrium will be the concentration of the nitro-compound added initially, and the value of E can be calculated by taking the extrapolated value of I/I_0 at equilibrium, and substituting the necessary values in equation (10). The figures obtained for E are given in Table VI.

The extinction coefficient E being known, the change in concentration of the absorbing substance can be determined by transforming equation (10) thus

$$c = -(1/Ed') \cdot \log I/I_0 \quad . \quad . \quad . \quad . \quad . \quad (11)$$

and this gives the values of c appearing in Table VI (cols. 3 and 4).

By substituting the calculated values of c in the unimolecular formula

$$k = 1/t \cdot \log_e (c_0 - c_e)/(c_t - c_e) \quad . \quad .$$

where c_0 is the initial, and c_e the equilibrium concentration, and c_t the concentration at time t, we obtain a similar velocity coefficient to that resulting from the conductivity measurements (see Table VI, cols. 4 and 7). The high initial values of k are probably due to difficulties in mixing, but any error in the zero time would affect measurements of extinction coefficients and of conductivity equally.

By interpolating values of the specific conductivity at the same temperature and times as the calculated concentrations, the molecular conductivities can be calculated. These are summarised in Table II: v is the dilution, l_t the interpolated specific conductivity, and in the last column is given a value proportional to molecular conductivity, which is practically constant over the range of dilutions concerned. Franklin (*Z. physikal. Chem.*, 1909, **69**, 272) finds a change of only about 2% over this range of dilutions, which is less than the experimental error.

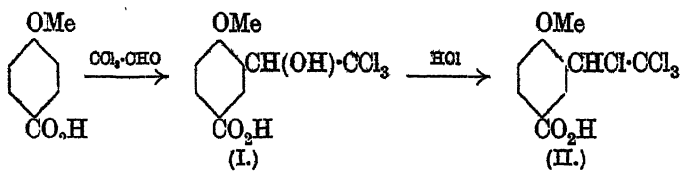
Results.

The thickness of the solution was in all cases 3·83 cm., being the length of the middle portion L_1 of the reaction tube (Fig. 3). The concentrations given in Tables VI and VII are in g.-mols. per litre, and the galvanometer deflexions, d, in mm.

(1) m-*Dinitrobenzene* (*Plates I and II*).—The alcoholic solution contained 0·1 g. of *m*-dinitrobenzene in 100 c.c.; 0·1 c.c. of this solution was added from a pipette to the reaction vessel, the volume of which was 3·50 c.c. Since the molecular weight of *m*-dinitrobenzene is 168, the dilution of the ammonia solution was 5880 litres. In Tables VI and VII are given the results at a number of wavelengths. For the extinction coefficient measurements, t is the mean time of the exposure; when conductivity measurements were made simultaneously, the figure given is for a time mid-way between the beginning and the end of the exposure.

In a further experiment at − 38° (Plate II) similar values of k were obtained. These are not given, since there are no data for the specific conductivity of *m*-dinitrobenzene at this temperature.

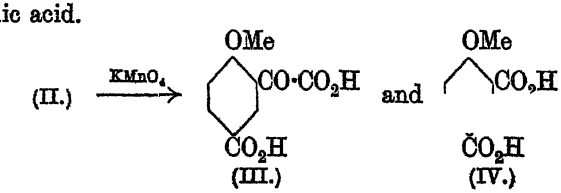
(2) 2 : 4-*Dinitrotoluene*.—The change in the intensity of the light falling on the plate was much greater than in the experiments with *m*-dinitrobenzene, since the reaction was followed over a greater range of concentrations. The range of exposures was so great that the Schwarzschild relation, $D = k I^T$, no longer held. It was therefore necessary to employ another method of calibrating the photographic plate. Dilute aqueous solutions of permanganate of known concentrations (less than $M/1000$) were placed in the cell, and used to determine the manner in which the intensity on the photographic plate varied with the concentration of the solution in



CCCLXXXIII.—*The Condensation of Chloral with Anisic Acid, with* p-*Nitroanisole, and with* 2 : 6-*Dichloroquinol.*

By FREDERICK DANIEL CHATTAWAY and FERNANDO CALVET.

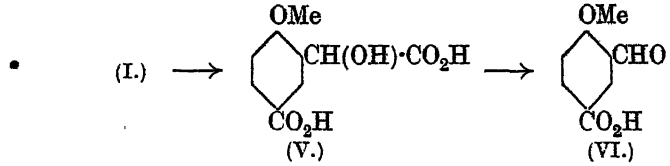
MANY phenols substituted in the para-position readily condense with chloral under the influence of concentrated sulphuric acid and form derivatives of 1 : 3-benzdioxin (Chattaway, J., 1926, 2720; Chattaway and Calvet, J., 1927, 685; this vol., p. 1088; Chattaway and Morris, J., 1927, 2083).



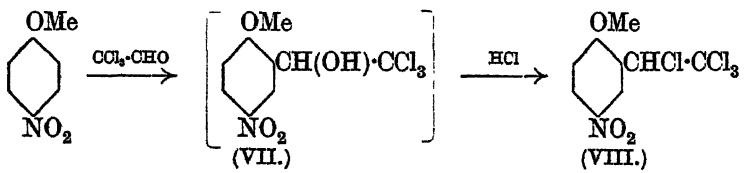
When, however, the formation of the heterocyclic benzdioxin ring is prevented by replacement of the phenolic hydroxyl by an alkyloxy-group, only one molecule of chloral reacts and a single βββ-trichloro-α-hydroxyethyl group, $\cdot CH(OH)\cdot CCl_3$, is introduced into the nucleus in a position ortho to the alkyloxy-group. For example, anisic acid condenses thus to form 5-*carboxy*-2-*methoxy*-1-βββ-*trichloro*-α-*hydroxyethylbenzene* (I).

This compound can be isolated during the first stages of the action. If, however, this be prolonged for many days, hydrogen chloride, which is slowly produced by the decomposition of some small amount of the chloral, replaces the α-hydroxyl group by a chlorine atom and the final product is 5-*carboxy*-2-*methoxy*-1-αβββ-*tetrachloroethylbenzene* (II).

(I.) (II.)

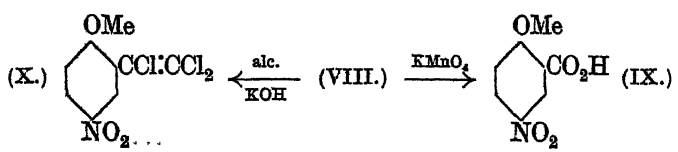


Its constitution has been established by oxidising it with an alkaline solution of potassium permanganate; it then yields a mixture of 5-*carboxy*-2-*methoxyphenylglyoxylic acid* (III), which gives a very well-defined *phenylhydrazone*, and 4-*methoxyisophthalic acid* (IV), which on hydrolysis of its methoxy-group yields 4-hydroxy*iso*-phthalic acid.



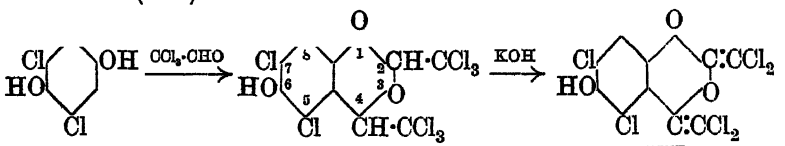
(III.) (IV.)

5-Carboxy-2-methoxy-1-βββ-trichloro-α-hydroxyethylbenzene, which melts about 73° higher than the corresponding 2-



derivative (Chattaway and Calvet, J., 1927, 689), is a comparatively stable substance, the methoxy-group not being easily hydrolysed. When the substance is heated with concentrated sulphuric acid on a water-bath, hydrogen chloride is liberated and *4-methoxyisophthalaldehydic acid* (VI) is formed, probably by elimination of formic acid from the 5-carboxy-2-methoxymandelic acid (V) which must be the first product of the hydrolysis.

p-Nitroanisole condenses with chloral in a similar manner in presence of concentrated sulphuric acid. When the action is prolonged, *5-nitro-2-methoxy-1-αβββ-tetrachloroethylbenzene* is formed (VIII). The intermediate product of the action, 5-nitro-2-methoxy-1-βββ-trichloro-α-hydroxyethylbenzene (VII), has not actually been isolated; but its formation is certain, since when the solution of *p*-nitroanisole and chloral in concentrated sulphuric acid is saturated at the beginning with hydrogen chloride the final product is formed much more rapidly and completely than when the necessary hydrogen chloride is formed by the comparatively slow decomposition of the chloral.



The constitution of the final condensation product was established by oxidising it with potassium permanganate in acetone solution; it then yielded 5-nitro-2-methoxybenzoic acid (IX), identical with the product obtained by nitration of *o*-methoxybenzoic acid. When acted upon by boiling alcoholic potash, it lost one molecule of hydrogen chloride and yielded *αββ-trichloro-5-nitro-2-methoxystyrene* (X).

It has been shown (*loc. cit.*) that, although many substituents in a position ortho to the phenolic hydroxyl hinder the formation of a

benzdioxin ring, they have little or no effect when in a meta-position. Condensation also proceeds in the usual manner when both meta-positions are thus occupied. For example, 2 : 6-dichloroquinol, in which both positions meta to one of the two hydroxyls are occupied by chlorine atoms, condenses readily, under the influence of concentrated sulphuric acid, with two molecules of chloral, yielding 5 : 7-*dichloro*-6-*hydroxy*-2 : 4-*bistrichloromethyl*-1 : 3-*benzdioxin* (XI), only the hydroxyl group which has both the adjacent *o*-positions unoccupied taking an active part in the reaction.

The heterocyclic dioxin ring of this condensation product shows unusual resistance to the action of alcoholic potash, which only removes a molecule of hydrogen chloride from each of the side chains and forms 5 : 7-*dichloro*-6-*hydroxy*-2 : 4-*bisdichloromethylene*-1 : 3-*benzdioxin* (XII).

(XI.) (XII.)

The benzdioxin ring in 6-amino-2 : 4-bistrichloromethyl-1 : 3-benzdioxin behaves similarly (see this vol., p. 1089).

EXPERIMENTAL.

5-*Carboxy*-2-*methoxy*-1-βββ-*trichloro*-α-*hydroxyethylbenzene* (I).—A solution of 40 g. (1 mol.) of anisic acid and 50 g. (1·2 mols.) of chloral hydrate in 400 c.c. of concentrated sulphuric acid was kept at the ordinary temperature for 10 hours and then poured into 2000 c.c. of water containing ice. A viscid mass separated which, after being heated with water, broke up into a mass of needle-shaped crystals; these were recrystallised from alcohol and from chloroform–light petroleum. 5-*Carboxy*-2-*methoxy*-1-βββ-*trichloro*-α-*hydroxyethylbenzene* is sparingly soluble in benzene and chloroform, practically insoluble in light petroleum, and easily soluble in boiling acetic acid and alcohol, from which it slowly separates as highly refractive, short prisms, m. p. 198—199° (Found: C, 39·9; H, 3·2; Cl, 35·8. $C_{10}H_9O_4Cl_3$ requires C, 40·1; H, 3·0; Cl, 35·6%).

5-*Carboxy*-2-*methoxy*-1-αβββ-*tetrachloroethylbenzene* (II).—(1) *By condensation of anisic acid and chloral in presence of concentrated sulphuric acid.* A solution of 50 g. of anisic acid and 60 g. of chloral hydrate in 500 c.c. of concentrated sulphuric acid was kept at the ordinary temperature for 8 days, hydrogen chloride being gradually formed in considerable quantity. When the clear resulting [illegible] was poured into 3000 c.c. of water 5-*carboxy*-2-*methoxy*-1-[illegible]

chloroethylbenzene separated as a voluminous white solid; this, after being washed with hot water, crystallised from alcohol in colourless needles (50 g.), m. p. 247—249° (Found: C, 37·85; H, 2·45; Cl, 44·65; *M*, 331. $C_{10}H_8O_3Cl_4$ requires C, 37·8; H, 2·5; Cl, 44·7%; *M*, 318). The substance is sparingly soluble in boiling water, moderately easily soluble in boiling benzene, chloroform, and light petroleum, and easily soluble in boiling alcohol and in aqueous alkalis.

(2) *By the action of hydrogen chloride upon 5-carboxy-2-methoxy-1-βββ-trichloro-α hydroxyethylbenzene.* A solution of 2 g. of the trichloro-compound in 20 c.c. of concentrated sulphuric acid was saturated with dry hydrogen chloride, kept at the ordinary temperature for 1 day, and then poured into 50 c.c. of water containing ice. The solid which separated was recrystallised from alcohol; it melted at 247—249° and was identical in every respect with the substance described in (1).

Action of Concentrated Sulphuric Acid on 5-Carboxy-2-methoxy-1-βββ-trichloro-α-hydroxyethylbenzene.—A solution of 10 g. of the trichloro-compound in 100 c.c. of concentrated sulphuric acid was heated on a water-bath for 45 minutes until hydrogen chloride ceased to be evolved. It was then cooled and poured into 500 c.c. of water containing ice. The *4-methoxyisophthalaldehydic acid* (VI) that separated (yield, 4·5 g.) crystallised from alcohol in very small, colourless plates, m. p. 244—245° (Found: C, 59·5; H, 4·7. $C_9H_8O_4$ requires C, 60·1; H, 4·45%). When heated with 2 : 4-dichlorophenylhydrazine it yielded the 2 : 4-*dichlorophenylhydrazone*, which crystallised from alcohol in very small, pale yellow needles, m. p. 303—305° (decomp.) (Found: Cl, 20·85. $C_{15}H_{12}O_3N_2Cl_2$ requires Cl, 20·9%).

Oxidation of 5-Carboxy-2-methoxy-1-αβββ-tetrachloroethylbenzene. Isolation of 4-Methoxyisophthalic Acid (IV) *and 5-Carboxy-2-methoxyphenylglyoxylic Acid* (III).—5-Carboxy-2-methoxy-1-αβββ-tetrachloroethylbenzene (15 g.) was dissolved in 300 c.c. of boiling water containing an excess of sodium carbonate, and about 30 g. of finely powdered potassium permanganate were added gradually until it was no longer decolorised on continued boiling. The manganese dioxide was filtered off, and the colourless filtrate made acid with hydrochloric acid; *4-methoxyisophthalic acid* (4·5 g.) then separated. It was several times recrystallised successively from acetic acid, dilute alcohol, and finally from boiling water, from which it separated in minute colourless needles, m. p. 275—276° (Found: C, 55·0; H, 4·3. $C_9H_8O_5$ requires C, 55·1; H, 4·1%).

When heated for 5—10 minutes with hydriodic acid (b. p. 127°), it gave 4-hydroxyisophthalic acid, m. p. 310°.

The aqueous acid mother-liquor from which the 4-methoxy*iso*-phthalic acid had separated was repeatedly extracted with ether. Evaporation of the ether left *5-carboxy-2-methoxyphenylglyoxylic acid* as a crystalline, colourless solid; this was easily soluble in boiling acetic acid, from which it separated in small colourless prisms, m. p. 254—255° (Found: C, 53·3; H, 3·8. $C_{10}H_8O_6$ requires C, 53·6; H, 3·6%).

It reacts with hydrazines to form sparingly soluble hydrazones. The *phenylhydrazone* separates from boiling alcohol in pale yellow, microscopic prisms, m. p. 231° (decomp.) (Found: C, 61·0; H, 4·6; N, 8·9. $C_{16}H_{14}O_5N_2$ requires C, 61·2; H, 4·5; N, 8·9%).

5-Nitro-2-methoxy-1-αβββ-tetrachloroethylbenzene (VIII).—A solution of 50 g. of *p*-nitroanisole (1 mol.) and 60 g. of chloral hydrate (1·1 mols.) in 450 c.c. of concentrated sulphuric acid was kept at the ordinary temperature, hydrogen chloride being slowly liberated. Crystals of *5-nitro-2-methoxy-1-αβββ-tetrachloroethylbenzene*, which began to appear after 10 to 12 days, were separated after 4 weeks, well washed with water, and recrystallised from alcohol (yield, 33 g.). The substance is insoluble in water, very sparingly soluble in light petroleum, and easily soluble in boiling acetone, benzene, and alcohol, from which it separates in slightly yellow needles, m. p. 131—132° (Found: N, 4·4; Cl, 44·4; *M*, cryoscopic in benzene, 340. $C_9H_7O_3NCl_4$ requires N, 4·4; Cl, 44·5%; *M*, 319).

When the condensation of chloral with *p*-nitroanisole was carried out in concentrated sulphuric acid saturated with hydrogen chloride, separation of the product began on the third day and was practically complete by the eighth day.

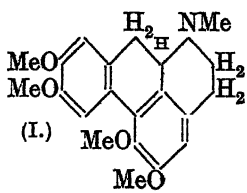
Action of Potassium Hydroxide on 5-Nitro-2-methoxy-1-αβββ-tetrachloroethylbenzene: Formation of αββ-Trichloro-5-nitro-2-methoxystyrene (X).—The tetrachloro-compound (2 g.) was heated for a short time with 25 c.c. of a mixture of equal parts of alcohol and a 50% aqueous solution of potassium hydroxide. As the reaction proceeded, *αββ-trichloro-5-nitro-2-methoxystyrene* separated as an oil, which solidified on cooling and then crystallised from alcohol in pale yellow, shining plates, m. p. 94—95° (Found: N, 4·9; Cl, 37·6. $C_9H_6O_3NCl_3$ requires N, 4·95; Cl, 37·7%).

Oxidation of 5-Nitro-2-methoxy-1-αβββ-tetrachloroethylbenzene to 5-Nitro-2-methoxybenzoic Acid (IX).—Potassium permanganate (30 g.) was added during 48 hours to 5 g. of 5-nitro-2-methoxy-1-αβββ-tetrachloroethylbenzene dissolved in 100 c.c. of boiling acetone. After 48 hours' boiling, the solid formed was separated from the cooled liquid and extracted with 100 c.c. of alcohol. Partial evaporation of the extract gave needles of potassium 5-nitro-2-methoxybenzoate, from which the acid. m. p. 161°, was obtained (Found:

C, 48·85; H, 3·4; N, 7·7. Calc. for $C_8H_7O_5N$: C, 48·7; H, 3·5; N, 7·1%), identical with a specimen prepared by the method of Simonsen and Rau (J., 1917, **111**, 228).

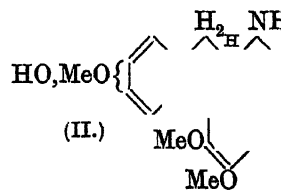
5:7-*Dichloro*-6-*hydroxy*-2:4-*bistrichloromethyl*-1:3-*benzdioxin* (XI).—To a solution in 250 c.c. of concentrated sulphuric acid of 25 g. (1 mol.) of 2:6-dichloroquinol, obtained by oxidising 2:4:6-trichlorophenol with cold fuming nitric acid and reducing the 2:6-dichlorobenzoquinone formed by sulphur dioxide, 48 g. of chloral hydrate were added. The mixture was well shaken for ½ hour and kept for 3 days at the ordinary temperature. Ice was then added and 5:7-*dichloro*-6-*hydroxy*-2:4-*bistrichloromethyl*-1:3-*benzdioxin*, which separated as a viscid, colourless mass, was well washed with water and repeatedly crystallised from alcohol (yield, 41 g.). It was easily soluble in boiling alcohol, chloroform, and benzene and sparingly soluble in light petroleum and separated from these solvents in small, glistening, colourless plates, m. p. 114—115° (Found: C, 26·15; H, 1·0; Cl, 62·1. $C_{10}H_4O_3Cl_8$ requires C, 26·05; H, 0·85; Cl, 62·2%). It dissolved in aqueous alkalis and gave a greenish-brown colour with a solution of ferric chloride.

The phenolic hydroxyl group is easily acetylated when the compound is heated for a short time with acetyl chloride or acetic anhydride containing a drop of sulphuric acid. 5:7-*Dichloro*-6-*acetoxy*-2:4-*bistrichloromethyl*-1:3-*benzdioxin* crystallises from boiling alcohol, in which it is moderately easily soluble, in small, colourless prisms, m. p. 179—180° (Found: Cl, 57·2. $C_{12}H_6O_4Cl_8$ requires Cl, 57·0%).



5:7-*Dichloro*-6-*hydroxy*-2:4-*bisdichloromethylene*-1:3-*benzdioxin* (XII).—To a boiling solution of 5 g. of potassium hydroxide (9 mols.) in 50 c.c. of alcohol, 4·5 g. of 5:7-dichloro-6-hydroxy-2:4-bistrichloromethyl-1:3-benzdioxin (1 mol.) were added and the mixture was boiled under reflux for 15 minutes; 50 c.c. of hot water were then added and the alcohol was distilled off in a current of steam. From the cooled, acidified liquid, 5:7-*dichloro*-6-*hydroxy*-2:4-*bisdichloromethylene*-1:3-*benzdioxin* separated. It is easily soluble in boiling alcohol, chloroform, and carbon tetrachloride, from which it separates in small, compact, colourless crystals, m. p. 137—138° (Found: Cl, 55·5. $C_{10}H_2O_3Cl_6$ requires Cl, 55·6%). When dissolved in carbon tetrachloride, it does not combine with bromine at the ordinary temperature.

THE QUEEN'S COLLEGE, OXFORD. [*Received, August 30th*, 1928.]



CCCLXXXIV.—*The Constitution of Laurotetanine.*

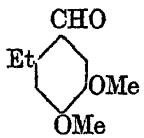
By GEORGE BARGER and ROBERT SILBERSCHMIDT.

LAUROTETANINE is an alkaloid discovered by Greshoff ("Verslag v.h. onderzoek v.d. Plantenstoffen Ned. Indie," 1890, 98; *Ber.*, 1890, **23**, 3537) in various *Lauraceæ;* injected, it causes tetanic convulsions. It was studied by Filippo (*Arch. Pharm.*, 1898, **236**, 601) and particularly by Gorter (*Bull. Jard. bot. Buitenzorg*, 1921, **3**, 180). The latter showed that the anhydrous base is $C_{16}H_{10}(OH)(NH)(OMe)_3$ and being impressed by the chemical and physiological resemblance of its *N*-methyl methyl ether to the alkaloid glaucine, he assumed the same carbon skeleton in both alkaloids. Now glaucine (I) has been synthesised from laudanosine by Gadamer (*Arch. Pharm.*, 1911, **249**, 680) and is a derivative of phenanthrene and *iso*quinoline. Since Gorter regarded the *N*-methyl

(I.)

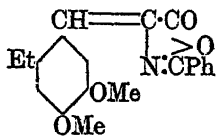
(II.)

methyl ether of laurotetanine as different from glaucine, he named it *iso*glaucine and considered the isomerism due to different positions of two methoxy-groups. A further study of these compounds and the products of their exhaustive methylation by Hofmann's method has, however, convinced us that glaucine and Gorter's "*iso*glaucine" are identical, so that laurotetanine may be represented by (II).



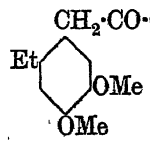
The one free hydroxyl group is as indicated in the benzene ring attached to two carbon atoms, for on oxidation of laurotetanine Gorter found that the benzene ring attached to three carbon atoms survives as a dimethoxybenzenetricarboxylic acid. The choice between the two possible formulæ indicated by (II) might perhaps be made by exhaustive methylation of laurotetanine ethyl ether and comparison of the product with two synthetic ethoxytrimethoxyethylphenanthrenes.

We carried out a number of preliminary experiments with this end in view. Although we could readily obtain from laurotetanine and glaucine a vinylphenanthrene and a phenanthrenecarboxylic acid, we were quite unable to decarboxylate the acid. We therefore decided to reduce the vinyl to the ethyl compound and attempted synthesis of the latter.

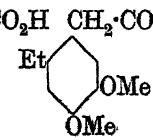


For this purpose the required 3 : 4-*dimethoxyethylben*[illegible]

obtained both by reducing 3 : 4-dimethoxyvinylbenzene (from 3 : 4-dimethoxyphenylethylcarbinol by Klages' method, *Ber.*, 1903, **36**, 3588) and by reducing acetoveratrone according to Clemmensen (*Ber.*, 1913, **46**, 1838). The latter alternative avoids the complications due to the polymerisation of the vinyl compound and is much the better method. Acetoveratrone was prepared by oxidation of the phenylmethylcarbinol as well as directly from veratrole; the latter route is the cheaper.

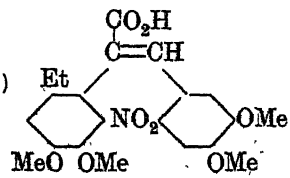


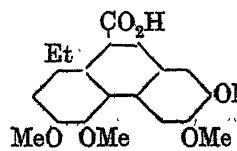
The dimethoxyethylbenzene was converted by Gattermann's reaction into an *aldehyde*, presumably (III), but this constitution has not been proved rigorously.



(III.)

(IV.)





(V.)

(VI.)

By condensation with hippuric acid to the *azlactone* (IV), hydrolysis to the *pyruvic acid* (V), and oxidation, a *dimethoxyethylphenylacetic acid* (VI) was obtained (compare Kropp and Decker, *Ber.*, 1909, **42**, 1184; Cain, Simonsen, and Smith, J., 1913, **103**, 1036; Haworth, Perkin, and Rankin, J., 1924, **125**, 1686). This was condensed with 6-nitro-3 : 4-dimethoxybenzaldehyde to the *nitro-acid* (VII), which after reduction and diazotisation was expected to yield a *phenanthrenecarboxylic acid* (VIII). The product of the decarboxylation

(VII.)

(VIII.)

of (VIII) was very similar to that obtained by the degradation of laurotetanine, but did not appear to be identical with it. Further work will be necessary to clear up this discrepancy.

EXPERIMENTAL.

A. *Exhaustive Methylation of Laurotetanine.*

Like Gorter, we prepared the alkaloid from the bark of *Litsea citrata* from Java, using, however, a different process from the usual Stas–Otto method employed by Gorter and by Filippo, for by extraction of an alkaline solution with immiscible solvents we obtained hardly any crystalline alkaloid. An alcoholic extract prepared for us by Messrs. Duncan, Flockhart and Co. of Edinburgh was a thick, tarry mass representing about 10% by weight of the

bark. We dissolved it in two-thirds of its weight of hot glacial acetic acid, poured the solution into 5—6 volumes of water with vigorous mechanical stirring, and filtered off a precipitate (A). The brown filtrate, on being made slightly acid to litmus by addition of ammonia, gave a precipitate (B), partly composed of a weak base which probably contained several free hydroxyl groups and was readily oxidised. This alkaloid, which has some properties in common with boldine, a dihydroxydimethoxyphenanthrene alkaloid occurring in *Peumus Boldus* (*Monimiaceæ*, related to *Lauraceæ*), could not be crystallised. To the filtrate from (B) we added excess of ammonia and obtained a voluminous, pale yellow precipitate of crude laurotetanine, which was washed free from ammonia and dried on a porous tile in a vacuum. Precipitate (A) was redissolved in glacial acetic acid and treated as before, whereby it yielded a further quantity of crude laurotetanine. The dried alkaloid was powdered, mixed with sand, and extracted with ether for several days in a Soxhlet apparatus. Crystalline material soon began to separate from the ether, in which it is very sparingly soluble. It was recrystallised from acetone by the addition of a few drops of water. The hydrated alkaloid melted in its water of crystallisation at 124—134° (Gorter gives 125°; Filippo, 134°). It did not darken on exposure to light as stated by Gorter (at Buitenzorg). Yield, 0·3—0·4% (Gorter obtained 0·38%).

Complete Methylation. Dimethyl-laurotetanine Methiodide, $C_{22}H_{38}O_4NI$.—Preliminary experiments, in which laurotetanine and methyl iodide were heated in methyl-alcoholic sodium hydroxide, yielded two crystalline iodides, ultimately identified as the methiodide and methine hydriodide, but as the yield was unsatisfactory, diazomethane was used for the first step. Laurotetanine (1 g.) in 10 c.c. of methyl alcohol was mixed with an ethereal solution of diazomethane from 7 c.c. of nitrosomethylurethane. Next day, after evaporation, the methyl ether was separated by means of sodium hydroxide and treated as syrup with excess of methyl iodide in methyl alcohol. The methiodide, obtained in a yield of 60%, formed bundles of colourless needles, m. p. 210°, the same as that recorded for glaucine methiodide; the melting point remained constant on recrystallisation and did not rise to 226°, that given by Gorter for "*iso*glaucine methiodide." The methiodide was very sparingly soluble in water and could be completely extracted from aqueous solution by chloroform.

Dimethyl-laurotetaninemethine, $C_{22}H_{27}O_4N$.—The methiodide (0·5 g.) was heated for 5 hours with 40 c.c. of 10% alcoholic potassium hydroxide. The solution, which became slightly red, was concentrated and water was added; an oily base then se[parated]

When this was neutralised with acid, the *hydriodide* of the methine separated in colourless, rhomb-shaped leaflets, m. p. 265°, almost insoluble in water and in alcohol (Found: I, 26·2. $C_{22}H_{27}O_4N,HI$ requires I, 25·6%). The free methine, isolated after addition of ammonia and extraction with ether, could not be crystallised, and remained oily after distillation at 200° in a high vacuum. Yield, 0·4 g. The methine tenaciously retained a small quantity of an impurity, which gave it a pink colour and was less soluble in hot water than in cold. This impurity was absent from the methine prepared from glaucine, which could be obtained in colourless needles, m. p. 76°, from the dry ethereal solution, and probably accounts for the somewhat lower melting points of Gorter's "*iso*-glaucine" salts, as compared with those of glaucine.

Dimethyl-laurotetaninemethine methiodide, $C_{23}H_{30}O_4NI$, obtained on mixing the components in ethereal solution, formed white needles, m. p. 276°, very sparingly soluble in hot water.

2 : 3 : 5 : 6-*Tetramethoxy*-8-*vinylphenanthrene*.—The methine methiodide (0·37 g.; 0·75 millimol.) was heated with 40 c.c. of 10% methyl-alcoholic potassium hydroxide on the water-bath, the trimethylamine evolved being swept into 0·1*N*-hydrochloric acid. After 6 hours, 6·5 c.c. of the acid (= 90% of the theoretical) had been neutralised. (The trimethylamine was isolated as the chloroplatinate, m. p. 253° after crystallising from alcohol. Found: Pt, 37·2. Calc., 36·7%.) When the solution was concentrated, crystals separated; the quantity was increased by addition of water and neutralisation. On extraction with ether and crystallisation from alcohol, slightly pink, rhomb-shaped plates, m. p. 142°, were obtained. They decolorised potassium permanganate in cold acetone. Yield, 60% (Found: C, 74·05, 74·0; H, 6·3, 6·4. $C_{20}H_{20}O_4$ requires C, 74·0; H, 6·2%).

2 : 3 : 5 : 6-*Tetramethoxyphenanthrene*-8-*carboxylic Acid*.—To a cold solution of 5·1 g. of the vinyl compound in 10 c.c. of acetone, 0·175 g. of potassium permanganate (= 5O) was added during 1 hour. The manganese dioxide was filtered off and reduced with bisulphite and the solution was added to the residue left on evaporation of the acetone filtrate. Ether extracted from the alkaline solution a little unchanged vinyl compound and then, after acidification, a substance which crystallised from acetone–water or benzene–ligroin in yellow needles, m. p. 215°, very soluble in ether (Found: equiv., by back titration, 339. $C_{19}H_{18}O_6$ requires equiv., 342).

B. *Exhaustive Methylation of Glaucine.*

The above degradation had not been carried out by Gadamer (*loc. cit.*), who deduced the constitution by converting laudanosine

into glaucine. We isolated the latter alkaloid from 10 kg. of leaves and pods of *Glaucium luteum* from the Royal Botanic Gardens, Edinburgh, and from the coast near Cockburnspath. Fischer's method (*Arch. Pharm.*, 1901, **239**, 426) was greatly simplified by utilising the minute solubility of glaucine hydriodide in the presence of potassium iodide, the glaucine salt being under these conditions almost as sparingly soluble as the precipitate with Mayer's reagent (limit at 1 : 10,000). The material was covered with water, heated to boiling, strained, passed through a mincer, stirred for 2—3 hours in the original solution after addition of 2% acetic acid, strained, and extracted a second time. The filtered extracts were concentrated in a vacuum to a half-syrupy consistency and filtered through glass wool. Potassium iodide was then dissolved in the solution; after 2 days, a layer of brownish crystals had separated. One recrystallisation from much alcohol gave long, silky needles, still slightly pink, m. p. 243° (yield, 0·2% of the fresh leaves and pods). Thus this alkaloid is readily accessible. The filtrate from the crystals gave with ammonia a small precipitate yielding the colour reactions of protopine (Fischer, *loc. cit.*).

To obtain the pure base, the iodide was shaken with aqueous ammonia and ether. The former retained the colouring matter and the latter left on evaporation colourless prisms, m. p. 118—119°, after several crystallisations.

We prepared glaucine methiodide, the methine, methine methiodide, the vinylphenanthrene, and the carboxylic acid. We also prepared the characteristic iodide of dimethyl-laurotetanine (from laurotetanine and diazomethane). We thus had six different compounds, each obtained from two natural sources. In all cases they were identical; these results, tabulated below, dispose of Gorter's alleged difference between glaucine and dimethyl-laurotetanine. We have also tabulated the melting points given by Warnat (*Ber.*, 1925, **58**, 2768) for mixtures of derivatives of dimethylboldine and glaucine. Warnat was the first to publish the Hofmann degradation of glaucine, after we had already carried it out independently.

	Dimethyl-lauro-tetanine alone.	Glaucine alone.	Glaucine + dimethyl-lauro-tetanine.	Glaucine + dimethyl-boldine.
Hydriodide	243°	243°	243°	239—241°
Methiodide	219	219	219	221
Methine hydriodide	264	264	263	—
Methine methiodide	276	278	276	276—278°
Vinylphenanthrene	142	142	142	142—14[illegible]
Phenanthrene acid	215	214	214	—[illegible]

Having established this identity, we carried out some ex[illegible]

as first steps in the determination of the position of the free hydroxyl in laurotetanine. In order to have a tetramethoxy-compound which could be synthesised, we attempted to decarboxylate the tetramethoxyphenanthrenecarboxylic acid. We entirely failed to do this, whether by distillation (when the acid sublimed at a high temperature), or by heating with lime, or by heating in glacial acetic acid. We therefore decided to base the comparison on the ethyl compound.

2 : 3 : 5 : 6-Tetramethoxy-8-ethylphenanthrene was prepared by reducing 0·485 g. (1·5 millimols.) of the vinyl compound (from glaucine), dissolved in the minimum amount of glacial acetic acid, which coloured the solution red, with hydrogen after addition of palladium chloride and gum arabic. The reaction stopped abruptly after 20 minutes, when 35 c.c. of hydrogen had been taken up. The solution was diluted with water, and the resulting mixture extracted with ether. The extract crystallised from methyl alcohol. Yield, 80%. The crystals were distilled in a high vacuum with the bath at 200°. The colourless distillate crystallised from alcohol in narrow plates, m. p. 120°.

Synthesis of 2 : 3 : 5 : 6-*Tetramethoxy*-8-*ethylphenanthrene.*

As we required large quantities of methyl vanillin and of veratrole, we paid some attention to the methylation of vanillin and of guaiacol, finally obtaining a practically quantitative yield by a rapid method.

Vanillin (152 g.; 1 mol.) is melted in a wide-mouthed bottle provided with a condenser, a stirrer, and two tap-funnels. With rapid stirring, 1·5 mols. (82 g.) of potassium hydroxide in 120 c.c. of water are run in at the rate of two drops a second, and 20 seconds after this has started, addition of 1·25 mols. (160 c.c.) of methyl sulphate is begun at the same rate. (The methyl sulphate has stood over potassium carbonate and is neutral to Congo.) The external heating is soon stopped. The reaction mixture keeps a pale reddish-brown and alkaline; green indicates an acid reaction. When three-quarters of the reagents have been added, the reaction mixture becomes turbid and separates into two layers. As soon as all has been run in (about 20 minutes from the start) the reaction mixture is poured into a porcelain basin. The upper layer solidifies to a hard, white mass of practically pure methyl vanillin, m. p. 43°. It is washed with water and dried. Yield, 165 g., or more than 99%. Veratrole was similarly obtained in a yield of 95% (after extraction with ether and distillation). Pure, crystalline guaiacol must be used. Acetoveratrone was obtained from veratrole and acetyl chloride by means of aluminium chloride in carbon disulphide

solution in a yield of 80% and was then reduced by Clemmensen's method (*Ber.*, 1913, **46**, 1838).

3 : 4-*Dimethoxyethylbenzene*.—720 G. of zinc, amalgamated for 1 hour with double the weight of 5% aqueous mercuric chloride solution, was washed and covered with 10% hydrochloric acid. The liquid was heated to boiling and 180 g. of acetoveratrone were added in the course of an hour. The boiling was continued for 5 hours, 50—100 c.c. of acid being added per hour. The oily layer removed by ether distilled mostly at 110—112°/9 mm.; the boiling point then suddenly rose to 230—240° and a polymeride distilled. Thus the lower fraction was at once pure and stable to permanganate. Yield, 68%. The substance could not be crystallised.

3 : 4-*Dimethoxy*-6-*ethylbenzaldehyde* (III).—To 54 g. of dimethoxyethylbenzene in 75 g. of anhydrous benzene, cooled by ice, 60 g. of freshly powdered aluminium chloride were slowly added, then 55 g. of hydrogen cyanide. Hydrogen chloride was passed for 3 hours at 0° and for ½ hour at 30°. Next day the imide was poured on ice and finally decomposed by a current of steam. The *aldehyde* distilled at 150—159°/9 mm. and crystallised on long standing in plates, m. p. 28—30°, very soluble in organic solvents (Found: C, 67·7; H, 7·2. $C_{11}H_{14}O_3$ requires C, 68·0; H, 7·3%). The semicarbazone formed colourless crystals, m. p. 197—199°.

3 : 4-*Dimethoxy*-6-*ethylbenzoic acid*, prepared by oxidising the aldehyde with alkaline permanganate, had m. p. 138° (Found: equiv., 210·5. $C_{11}H_{14}O_4$ requires equiv., 210).

Azlactone of 3 : 4-*Dimethoxy*-6-*ethylbenzylidenehippuric Acid* (IV).—A mixture of 39 g. of the aldehyde, 40 g. of hippuric acid, 82 c.c. of acetic anhydride, and 16 g. of sodium acetate was heated for 40 minutes on the water-bath. After cooling, the semi-solid mass was washed with much ether and with water; it then separated from hot alcohol, in which it was rather sparingly soluble, in yellow crystals, m. p. 155°. Yield, 66% (Found: C, 71·0; H, 6·0. $C_{20}H_{19}O_4N$ requires C, 71·2; H, 6·0%). The acid itself, m. p. 212°, was made by heating the lactone with 1% potassium hydroxide solution until it was colourless.

3 : 4-*Dimethoxy*-6-*ethylphenylpyruvic Acid* (V).—20 G. of the azlactone were boiled with 30 g. of potassium hydroxide in 100 c.c. of water, the ammonia evolved being swept into *N*-acid. In 1 hour 53 c.c. had been neutralised (= 94% of the theoretical). The solution was acidified with sulphur dioxide, and the benzoic acid filtered off. The solution, which contained the pyruvic acid as bisulphite compound, was acidified with hydrochloric acid, and heated under reduced pressure to remove sulphur dioxide. The crystalline precipitate separated. Recrystallised from [illegible]

acetic acid and from alcohol, it formed pale yellow crystals, m. p. 181°; yield, 71%.

3 : 4-*Dimethoxy*-6-*ethylphenylacetic Acid* (VI).—The keto-acid (10 g.) in a large excess of dilute sodium hydroxide solution was oxidised at 0° by 37 c.c. of 3% hydrogen peroxide. After neutralisation with sulphur dioxide (to keep the unchanged acid in solution) the oxidation product separated as an oil which solidified next day, and was extracted with ether. It formed slightly pink bundles of needles, m. p. 67°; yield, 78% (Found: equiv., 222·5. $C_{12}H_{16}O_4$ requires equiv., 224).

α-3 : 4-*Dimethoxy*-6-*ethylphenyl*-β-6-*nitro*-3 : 4-*dimethoxyphenylacrylic Acid* (VII).—A solution of 5 g. of the previous acid in methyl alcohol was neutralised by methyl-alcoholic potassium hydroxide and evaporated in a round-bottom flask. The potassium salt was dried in a vacuum at 120—130° for 3 hours, and 10 g. of 6-nitro-3 : 4-dimethoxybenzaldehyde (Pschorr, *Ber.*, 1899, **32**, 3412), 8 c.c. of acetic anhydride, and 0·2 g. of anhydrous zinc chloride were then added. The flask was fitted with a long air-condenser and dry nitrogen was very slowly passed over the mixture to prevent oxidation. The mixture was heated for 20 hours at 120°, and then for 1 hour on the water-bath after addition of 20 c.c. of water. It was then made alkaline with ammonia and filtered from a brown tar, which was re-extracted with ammonia. After charcoal treatment, acidification gave a voluminous precipitate of the crude *acid* (yield, 52%), which separated from hot methyl alcohol in yellow crystals, m. p. 208° after sintering at 203° (Found: equiv., 418. $C_{21}H_{23}O_8N$ requires equiv., 417).

Amino-acid from the above. The nitro-acid (2·08 g.; 5 millimols.) was dissolved in 20 c.c. of dilute ammonia, heated to 80°, and slowly added to a reduction mixture at the same temperature, prepared by adding 8 c.c. of 25% ammonia to 9·2 g. of ferrous sulphate (33 millimols.) in a little water. The mixture was shaken and left on the water-bath for 2 hours and filtered. Acetic acid precipitated from the dark brown solution a deep yellow, amphoteric precipitate, m. p. 192° in the crude state.

2 : 3 : 5 : 6-*Tetramethoxy*-8-*ethylphenanthrene*-9-*carboxylic Acid* (VIII) *and* 2 : 3 : 5 : 6-*Tetramethoxy*-8-*ethylphenanthrene* (?).—The above amino-acid (0·9 g.; 2·5 millimols.), dissolved in the calculated quantity of sodium carbonate solution, was mixed with 2·5 c.c. of *N*-sodium nitrite and dropped very slowly into 9 c.c. of well-cooled and stirred *N*-sulphuric acid. After filtration, the solution of the diazonium salt was heated for 2 hours on the water-bath; it then no longer coupled with β-naphthol. A reddish-brown acid separated on acidification, but could not be crystallised; yield, 0·5 g. (crude).

A small-scale experiment with amyl nitrite and copper powder in the cold yielded hardly any of the acid after 12 hours. The crude acid was decarboxylated by heating 0·2 g. in a bath at 230—250°/9 mm. An ethereal solution of the oily distillate, after being washed with sodium carbonate, was evaporated; the residue crystallised from hot methyl alcohol in pale brown leaflets, m. p. 106°, and 112° when mixed with the corresponding compound from laurotetanine. The product (some 40 mg.) was redistilled and crystallised as before; it was now completely colourless and melted at 118°, but the mixture with the laurotetanine derivative melted at 106°. The lowering of the melting point is as yet unexplained; it is not clear which of the two substances should first be suspected of having a wrong constitution assigned to it. Both substances showed sparing solubility in methyl alcohol.

Some preliminary experiments were also undertaken with laurotetanine ethyl ether, prepared by means of ethyl *p*-toluenesulphonate. The oily base gave a hydriodide, m. p. 198—200°, a methiodide, m. p. 223—226°, a methine methiodide, m. p. 275°, and a trimethoxyethoxyvinylphenanthrene, m. p. 139°.

6-*Nitro*-3-*methoxy*-4-*ethoxybenzaldehyde* (ethyl nitrovanillin) was prepared by adding ethyl vanillin to a mixture of equal parts of fuming and ordinary concentrated nitric acids. After distillation under reduced pressure, it melted at 159—160° and was resublimed in a vacuum at 130—140° (Found: C, 53·3; H, 4·8. $C_{10}H_{11}O_5N$ requires C, 53·3; H, 4·8%). The condensation of this aldehyde with potassium dimethoxyethylphenylacetate has not yet proceeded in normal fashion.

We wish to express our great indebtedness to Dr. R. Wind, Director of the Experimental Forestry Station, and to Dr. W. Docters van Leeuwen, Director of the Botanic Gardens, Buitenzorg, Java, for a supply of the bark of *Litsea citrata*; also to Professor W. Wright Smith, Director of the Royal Botanic Gardens, Edinburgh, for help in securing a quantity of *Glaucium luteum*, and to the Moray Fund of Edinburgh University for a grant towards the expenses of the research.

CCCLXXXV.—*Some Substitution Products of Azobenzene.*

By JAMES BURNS, HAMILTON MCCOMBIE, and HAROLD ARCHIBALD SCARBOROUGH.

AMONG the systems containing two phenyl nuclei which are of interest, from the point of view of substitution, is azobenzene. The order of substitution in this series derives its importance from the fact that the system contains two tervalent nitrogen atoms free from hydrogen atoms; it might be expected, therefore, that analogies in behaviour between this series and nitrosobenzene or the diacyl derivatives of aminodiphenyl (compare Scarborough and Waters, J., 1927, 1139) would be found. The formation of quinonoid compounds in this series is a possibility which must not be excluded as a factor which would influence in a marked manner the sequence in which progressive substitution would occur.

The first substitution reaction in this series was carried out by Laurent and Gerhardt (*Annalen*, 1850, **75**, 73), who examined the reaction between azobenzene and nitric acid. A dibromoazobenzene was obtained by Werigo (*Annalen*, 1865, **135**, 178; 1873, **165**, 199). An extensive study of the substitution products of azobenzene with nitric acid, sulphuric acid, and bromine, in which as many as four similar or dissimilar groups were introduced, was made by Janovsky (*Monatsh.*, 1881, **2**, 221; *et seq.*). The nature of the nitration products of azobenzene which were described by Janovsky was the subject of a mild criticism by Klinger and Zurdeeg (*Annalen*, 1889, **255**, 336); but it remained for Werner and Stiasny (*Ber.*, 1899, **32**, 3257) to point out that of some twelve mono-, di-, and tri-nitro-derivatives of azobenzene, described by Janovsky, there was not one which might be described as a single individual and as a consequence the structures assigned could only be justified in two cases where a reasonable degree of purity had been obtained.

An examination made in these laboratories by Mr. J. Dexter has shown that the destructive criticism of Werner and Stiasny is fully justified; further, he has shown that of the three monobromo- and two dibromo-azobenzenes described by Janovsky, only one mono- and one dibromo-azobenzene could be isolated.

In view of all these criticisms of the work of Janovsky, the remaining substitution products which he obtained cannot be accepted without revision or independent confirmatory evidence.

The number of direct substitution products of azobenzene itself whose constitution may be regarded as established is therefore limited to 4-nitroazobenzene, m. p. 149°, 4 : 4′-dinitroazobenzene,

m. p. 221°, 4-bromoazobenzene, m. p. 94°, 4 : 4′-dibromoazobenzene, m. p. 205°, and azobenzene-4-sulphonic acid, m. p. 127°. It would thus appear that only the two 4-positions are readily substituted.

The introduction of substituents into the molecule of any of the three possible methylazobenzenes (benzeneazotoluenes) does not appear to have been attempted. In an attempt to nitrate 4-methylazobenzene in acetic acid solution the initial substance was recovered, and a nitro-group could only be introduced by the action of fuming nitric acid; whereas 2- and 3-methylazobenzene nitrated easily in acetic acid solution to yield products substituted in the 4 : 4′-positions. On bromination 4-methylazobenzene could only be converted into 4′-*bromo*-4-*methylazobenzene* by the action of neat bromine, whereas 3-methylazobenzene was converted into 4-*bromo*-3-*methylazobenzene* by bromination in acetic acid solution. The product obtained by the action of bromine on 2-methylazobenzene is apparently not an azo-derivative and its constitution could not be elucidated. The nature of the substitution products of 2- and 4-methylazobenzenes indicates that the $C_6H_5{\cdot}N{:}N{\cdot}$ group is more strongly directive than the methyl group; but when in the 2- or 3-position the methyl group makes it possible to effect substitution by less drastic methods than when it occurs in the 4-position and must thus have an activating effect.

The presence of chlorine as a substituent in azobenzene causes further substitution to take place in the unsubstituted phenyl nucleus and, since the $C_6H_5{\cdot}N{:}N{\cdot}$ group is strongly *p*-directive, the entering substituent occupies the 4′-position. Thus on nitration, chlorination and bromination, 4-chloroazobenzene yielded 4′-*nitro*-, 4′-chloro-, and 4′-*bromo*-4-*chloroazobenzene*, respectively; similarly, 3-chloroazobenzene yielded 4′-*nitro*- and 4′-*bromo*-3-*chloroazobenzene*. This behaviour of the halogen atom was to be expected from a consideration of the results obtained in the diphenyl and benzophenone series.

The further substitution of 4-hydroxyazobenzene was first investigated by Noelting (*Ber.*, 1887, **20**, 2997), who showed that on nitration, in concentrated sulphuric acid solution, 4′-nitro-4-hydroxyazobenzene was formed; it has also been shown by Hewitt (J., 1900, **77**, 99) that if this nitration is carried out in nitric acid (*ca.* 20%) solution the product is 3-nitro-4-hydroxyazobenzene. This difference in behaviour was ascribed to the formation of a salt between the concentrated sulphuric acid and the azophenol, acting in its tautomeric form as quinonephenylhydrazone. In later communications Hewitt and Aston (*ibid.*, pp. 713, 811) have shown that bromination, in the presence of fused sodium acetate, 4-hydroxyazobenzene yielded a product substituted in the 3 : 5-positions.

whereas bromination in the absence of the sodium acetate yielded 3 : 5 : 4′-tribromo-4-hydroxyazobenzene. It has been found that 4-methoxyazobenzene on chlorination yielded 3 : 5-*dichloro*-4-*methoxyazobenzene*, and regulated bromination gave 3-*bromo*- and 3 : 5 : 4′-*tribromo*-4-*methoxyazobenzenes*. On nitration, 3 : 4′-*dinitro*-4-*methoxyazobenzene* was obtained. It is thus seen that the methoxyl group has a stronger directive effect than the $C_6H_5{\cdot}N{:}N{\cdot}$ group. Since two chlorine atoms enter the methoxylated nucleus successively, and since bromine appears to enter the 4′- and 5-positions simultaneously, it would seem that the $C_6H_5{\cdot}N{:}N{\cdot}$ group, though strongly *p*-directive, tends to lessen the reactivity of the nuclei to which it is attached. This view is supported by the parallel results which were obtained with 4-methoxybenzophenone (Blakey, Jones, and Scarborough, J., 1927, 2865).

The only substitution product of 4-aminoazobenzene or of its acetyl derivative whose structure is established is 4′-nitro-4-acetamidoazobenzene. This compound was formed on nitration in sulphuric acid solution (Friedländer, " Fortschritte in der Teerfarbenfabrikation," IV, 1021).

It has been found that 4-acetamidoazobenzene on chlorination, in acetic acid solution, yielded 3-*chloro*-4-*acetamidoazobenzene*. Attempts to introduce other substituents into the molecule of 4-acetamidoazobenzene failed.

Chlorination of 4-aminoazobenzene in carbon tetrachloride solution yielded an inseparable mixture of di- and tri-chloro-derivatives. In acetic acid solution, the base brominated smoothly and yielded 3 : 5-dibromo-4-aminoazobenzene (compare Berju, *Ber.*, 1884, **17**, 1403). Iodination and nitration were attempted under various conditions, but the product was always a tar.

The difference in structure of the two substitution products of 4-acetamidoazobenzene is the same as that observed in the case of 3-acetamidodiphenyl (Blakey and Scarborough, J., 1927, 3002) and must therefore be ascribed to the influence of a concentrated acid upon the acetamido-group and not to such a change in the structure of the azo-group as occurs in the case of 4-hydroxyazobenzene. The inactive nature of 4-acetamidoazobenzene was an unexpected factor in this section of the work.

For the determination of the structure of the substituted azobenzenes, at least three methods were available :

(*a*) The oxidation of a hydrazo-compound formed by the condensation of appropriately substituted hydrazines and *o*- and *p*-halogenonitrobenzenes.

(*b*) The complete reduction of the compound to its constituent bases, their separation, and identification.

(*c*) The condensation of appropriately substituted nitrosobenzenes and anilines.

Not one of the three methods is free from experimental difficulties, but since the third method leads to the most direct comparison it has been employed in nearly every case. This method, however, proves unsatisfactory or impossible when an *o*-nitro-group or an accumulation of nitro-groups is present in either the nitrosobenzene or the aniline molecule.

Experimental.

4-Methylazobenzene was obtained when a glacial acetic acid solution of equimolecular quantities of nitrosobenzene and *p*-toluidine was kept over-night. It separated from dilute alcohol in deep yellow plates, m. p. 72° (compare Mills, J., 1895, 67, 929).

4'-Nitro-4-methylazobenzene was prepared by keeping a solution of 5 g. of 4-methylazobenzene in 100 c.c. of nitric acid (*d* 1·5) below 5° for 2 hours. The semi-solid mass which was precipitated when the mixture was poured into water yielded 3·5 g. of pure product. The same substance was obtained by condensing *p*-nitrosotoluene with *p*-nitroaniline. It crystallised from alcohol in deep red needles, m. p. 183° (Found: N, 17·35. $C_{13}H_{11}O_2N_3$ requires N, 17·4%).

4'-Bromo-4-methylazobenzene.—A solution of 5 g. of 4-methylazobenzene in dry bromine (4 c.c.) was kept for some hours. The residue after removal of the excess of bromine with sodium bisulphite solution was repeatedly crystallised from alcohol and gave orange needles, m. p. 152° (Found: Br, 28·95. $C_{13}H_{11}N_2Br$ requires Br, 29·1%).

3-Nitro-4-methylazobenzene was obtained when 2-nitro-*p*-toluidine was condensed with nitrosobenzene. It separated from alcohol in long, golden needles, m. p. 105° (Found: N, 17·35. $C_{13}H_{11}O_2N_3$ requires N, 17·4%).

3-Bromo-4-methylazobenzene was prepared by condensing 2-bromo-*p*-toluidine with nitrosobenzene. It crystallised from alcohol in yellow needles, m. p. 84° (Found: Br, 29·0. $C_{13}H_{11}N_2Br$ requires Br, 29·1%).

ω-Bromo-4-methylazobenzene.—5 G. of 4-methylazobenzene were dissolved in 80 c.c. of a 10% solution of bromine in acetic acid together with 4 g. of fused sodium acetate and the solution was heated on the water-bath for 8 hours. After some days it deposited about 1 g. of red needles, m. p. 115° after recrystallisation from alcohol (Found: N, 10·25; Br, 29·1. $C_{13}H_{11}N_2Br$ requires N, 10·1; Br, 29·1%). The substance remaining in the acetic acid mother-liquor was unchanged 4-methylazobenzene. The product treated

with dilute aqueous-alcoholic potash, the bromine being liberated as potassium bromide.

3-Methylazobenzene was prepared by condensing nitrosobenzene with *m*-toluidine. The product was distilled under diminished pressure and frozen. It is a light red oil, b. p. 165°/15 mm., and solidifies as red needles, m. p. 18°.

4 : 4′-*Dinitro*-3-*methylazobenzene*.—A solution of 3-methylazobenzene in nitric acid (*d* 1·5) was maintained below 5° for 90 minutes. The product crystallised from alcohol in bright red needles, m. p. 183° (Found : N, 19·75. $C_{13}H_{10}O_4N_4$ requires N, 19·6%).

The compound was completely reduced with stannous chloride in alcoholic hydrochloric acid solution and the mixed bases were liberated and acetylated in pyridine solution. Diacetyl-*p*-phenylenediamine, m. p. 310°, was isolated from the mixture by crystallisation from acetone; the acetone mother-liquor was evaporated to dryness and the residue, repeatedly crystallised from glacial acetic acid, gave 2-methyldiacetyl-*p*-phenylenediamine, m. p. 224°.

4-*Bromo*-3-*methylazobenzene*.—5 G. of 3-methylazobenzene were dissolved in 40 c.c. of a 10% solution of bromine in acetic acid, and the mixture heated on the water-bath for 6 hours. The product separated from dilute alcohol in light yellow needles, m. p. 69° (Found : Br, 29·15. $C_{13}H_{11}N_2Br$ requires Br, 29·1%). It was also obtained when 6-bromo-*m*-toluidine was condensed with nitrosobenzene.

2-Methylazobenzene was obtained when nitrosobenzene was condensed with *o*-toluidine. The product, after distillation under diminished pressure, was a light red oil, b. p. 180°/20 mm.

4 : 4′-*Dinitro*-2-*methylazobenzene* was prepared by keeping a solution of 2-methylazobenzene in nitric acid (*d* 1·5) below 5°. It was crystallised from alcohol and from acetone, from which it separated in dark red needles, m. p. 220° (Found : N, 19·6. $C_{13}H_{10}O_4N_4$ requires N, 19·6%).

The compound was completely reduced with stannous chloride in alcoholic hydrochloric acid solution and the liberated bases were acetylated. Diacetyl-*p*-phenylenediamine, m. p. 310°, and 2-methyldiacetyl-*p*-phenylenediamine, m. p. 224°, were isolated and identified by comparison with synthetic products.

Action of Bromine on 2-*Methylazobenzene*.—A solution of 5 g. of 2-methylazobenzene in 120 c.c. of a 10% solution of bromine in glacial acetic acid containing 5 g. of fused sodium acetate, after standing at room temperature for some hours, deposited white needles (4 g.), m. p. 210° after recrystallisation from much acetone (Found : C, 35·0, 35·4; H, 1·75, 1·65; N, 6·6, 6·4; Br, 57·5, 57·3; *M*, in bromoform, 390, 403. $C_{13}H_9N_2Br_3$ requires C, 36·0; H, 2·1;

N, 6·5; Br, 55·4%; *M*, 433). This *substance* appeared to be unattacked by aqueous permanganate or by stannous chloride in alcoholic hydrochloric acid solution.

4-Chloroazobenzene was obtained when *p*-chloroaniline was condensed with nitrosobenzene. It separated from alcohol in red plates, m. p. 92°.

4-Chloro-4'-bromoazobenzene.—5 G. of 4-chloroazobenzene were intimately mixed with 0·5 g. of ferric chloride, and 4 g. of bromine added; after the reaction had become less violent, 10 c.c. of water were added and the paste was heated on the water-bath for 1 hour. The product crystallised from acetone in bright yellow needles, m. p. 195° (Found: 0·1859 g. gave 0·2097 g. of silver halides. Theory requires 0·2095 g.).

The same product was obtained when *p*-chloronitrosobenzene was condensed with *p*-bromoaniline.

4 : 4'-Dichloroazobenzene.—5 G. of 4-chloroazobenzene were intimately mixed with 0·5 g. of ferric chloride and chlorine in excess was passed into the molten mass at water-bath temperature. After the mass had solidified, it crystallised from acetone in light yellow needles, m. p. 188° (Found: Cl, 28·4. Calc. for $C_{12}H_8N_2Cl_2$: Cl, 28·3%). Busch and Hobein (*Ber.*, 1907, **40**, 2099) give m. p. 184°.

p-Chloronitrosobenzene was condensed with *p*-chloroaniline in acetic acid solution and the same product was obtained.

4 : 4'-Dichloroazoxybenzene.—5 G. of 4 : 4'-dichloroazobenzene, dissolved in acetic acid, were treated with 8 g. of "Hyperol," added in small portions; the temperature was that of the water-bath. The product separated on standing over-night and crystallised from alcohol in light straw-coloured needles, m. p. 157° (Found: Cl, 26·7. $C_{12}H_8ON_2Cl_2$ requires Cl, 26·6%).

4-Chloro-4'-nitroazobenzene was prepared by dissolving 4-chloroazobenzene in nitric acid (*d* 1·5) and keeping this solution below 10° for 30 minutes. It separated from alcohol in long red needles, m. p. 169° (Found: Cl, 13·45. $C_{12}H_8O_2N_3Cl$ requires Cl, 13·55%).

The same compound was obtained when *p*-nitroaniline was condensed with *p*-chloronitrosobenzene, in acetic acid solution, at the temperature of the water-bath.

3-Chloroazobenzene was prepared by the condensation of nitrosobenzene with *m*-chloroaniline. It separated from alcohol in orange-red needles, m. p. 68° (compare Bamberger, *Ber.*, 1896, **29**, 103).

3-Chloro-4'-nitroazobenzene.—5 G. of 3-chloroazobenzene were dissolved in 80 c.c. of nitric acid (*d* 1·16) and the temperature was maintained at 0° for 20 minutes. The product separated from alcohol in red needles, m. p. 129° (Found: N, 16·15. $C_{12}H_8O_2N_3Cl$ requires N, 16·1%).

The same compound was obtained when *m*-chloronitrosobenzene was condensed with *p*-nitroaniline.

3-*Chloro*-4'-*bromoazobenzene*.—5 G. of 3-chloroazobenzene were ground into a paste with 5 c.c. of a concentrated ferric chloride solution, 5 c.c. of bromine were added, and the mixture was heated on the water-bath for 30 minutes. After repeated crystallisations from alcohol the product separated in deep yellow needles, m. p. 128° (Found : 0·1736 g. gave 0·1947 g. of silver halides. Theory requires 0·1950 g.). The same product was obtained when *m*-chloronitrosobenzene was condensed with *p*-bromoaniline.

4-Methoxyazobenzene was prepared by condensing nitrosobenzene with *p*-anisidine. It separated from alcohol in bright yellow plates, m. p. 64°.

3-*Bromo*-4-*methoxyazobenzene*.—5 G. of 4-methoxyazobenzene, 4 g. of fused sodium acetate, and 7·5 g. of bromine in 100 c.c. of acetic acid were heated on the water-bath for 4 hours. The product separated from alcohol in long yellow needles, m. p. 78° (Found : Br, 27·65. $C_{13}H_{11}ON_2Br$ requires Br, 27·5%).

2-*Bromo*-4-*nitroanisole* was prepared by adding bromine (1 mol.) to 4-nitroanisole in the presence of a little pyridine; the product separated from dilute alcohol in long needles, m. p. 108° (Found : Br, 34·6. $C_7H_6O_3NBr$ requires Br, 34·5%). The corresponding base, obtained by reduction with stannous chloride in alcoholic hydrochloric acid solution, was condensed with nitrosobenzene, and 3-bromo-4-methoxyazobenzene resulted.

3 : 4'-*Dibromo*-4-*methoxyazobenzene* was obtained when *p*-bromonitrosobenzene was condensed with 2-bromo-4-anisidine. It separated from alcohol in light yellow needles, m. p. 123° (Found : Br, 43·25. $C_{13}H_{10}ON_2Br_2$ requires Br, 43·3%).

3 : 4' : 5-*Tribromo*-4-*methoxyazobenzene*.—(*a*) A solution of 5 g. of 4-methoxyazobenzene and 10 g. of fused sodium acetate in 100 c.c. of a 30% solution of bromine in acetic acid was heated on the water-bath for 24 hours and finally refluxed for about 30 minutes. Crystals separated on cooling. (*b*) 3-Bromo- and 3 : 4'-dibromo-4-methoxyazobenzenes were treated in the same manner. The *compound* crystallised from much alcohol in yellow needles, m. p. 130° (Found : Br, 53·6. $C_{13}H_9ON_2Br_3$ requires Br, 53·5%).

3 : 5-*Dichloro*-4-*methoxyazobenzene* was prepared by passing dry chlorine into a mixture of 5 g. of 4-methoxyazobenzene and 5 g. of sodium acetate in 100 c.c. of acetic acid until the solution was saturated. It crystallised from alcohol in long yellow needles, m. p. 98° (Found : Cl, 25·35. $C_{13}H_{10}ON_2Cl_2$ requires Cl, 25·3%).

3 : 5-*Dichloro*-4-*hydroxyazobenzene* was obtained when (*a*) 3 : 5-dichloro-4-methoxyazobenzene was refluxed with a mixture of

constant-boiling hydrobromic acid and acetic acid for 8 hours; and (*b*) nitrosobenzene was condensed with 2 : 6-dichloro-4-aminophenol in acetic acid solution. It separated from alcohol in brownish needles, m. p. 116° (Found : Cl, 26·5. $C_{12}H_8ON_2Cl_2$ requires Cl, 26·6%).

3 : 4′-*Dinitro*-4-*methoxyazobenzene*.—A solution of 5 g. of 4-methoxyazobenzene in 30 c.c. of sulphuric acid was treated with 5 g. of potassium nitrate and kept for 24 hours. The product separated from acetone in bright red needles, m. p. 190° (Found : N, 18·6. $C_{13}H_{10}O_5N_4$ requires N, 18·55%). The compound was completely reduced with stannous chloride in alcoholic hydrochloric acid solution and the bases were liberated and acetylated in pyridine solution. Diacetyl-*p*-phenylenediamine, m. p. 310°, was isolated.

4-Aminoazobenzene was prepared according to Staedel and Bauer (*Ber.*, 1886, **19**, 1953) and converted into 4-acetamidoazobenzene with acetic anhydride; this separated from dilute alcohol in needles, m. p. 144°.

3-*Chloro*-4-*acetamidoazobenzene*.—A 5% solution of 4-acetamidoazobenzene in glacial acetic acid together with an excess of fused sodium acetate was treated with dry chlorine at 10° until the solution was saturated. The product crystallised from alcohol in orange plates, m. p. 134° (Found : Cl, 13·0. $C_{14}H_{12}ON_3Cl$ requires Cl, 13·0%).

3-*Chloro*-4-*aminoazobenzene* was obtained when the acetyl derivative was refluxed with alcoholic hydrochloric acid for 6 hours. The base, which was liberated with dilute ammonia, crystallised from dilute alcohol in deep yellow needles, m. p. 99·5° (Found : Cl, 15·2. $C_{12}H_{10}N_3Cl$ requires Cl, 15·3%). The compound was diazotised in alcoholic solution and, after refluxing, 3-chloroazobenzene, m. p. 67·5°, was isolated.

2-*Chlorobenzidine* was obtained when 3-chloroazobenzene was refluxed with stannous chloride in alcoholic hydrochloric acid solution for 2 hours. It separated from dilute alcohol in long needles, m. p. 113° (Found : Cl, 16·3. $C_{12}H_{11}N_2Cl$ requires Cl, 16·2%).

3 : 5-*Dibromo*-4-*aminoazobenzene*.—10 G. of 4-aminoazobenzene, dissolved in 100 c.c. of acetic acid, together with 10 g. of fused sodium acetate, were treated with 180 c.c. of a 10% solution of bromine in acetic acid at 15°. The base crystallised from much alcohol in light yellow needles, m. p. 168° (compare Hewitt, *Ber.*, 1908, **41**, 1986) (Found : Br, 44·9. Calc. for $C_{12}H_9N_3Br_2$: Br, 45·05%). On reduction with stannous chloride in alcoholic hydrochloric acid solution a mixture of aniline and 2 -dibromo-*p*-phenylenedia[illegible] was obtained. The latter base crystallised from water in long needles, m. p. 138° (Found : Br, 60·15. Calc. for C[illegible]

Br, 60·15%). Hewitt and Walker (J., 1907, **91**, 1141) give m. p. 137°.

3 : 5-*Dibromoazobenzene* was obtained when (*a*) 3 : 5-dibromo-4-aminoazobenzene was diazotised with amyl nitrite in alcoholic solution; or (*b*) nitrosobenzene was condensed with 3 : 5-dibromoaniline. It separated from alcohol in dark red needles, m. p. 104° (Found: Br, 46·9. $C_{12}H_8N_2Br_2$ requires Br, 47·0%). On bromination in acetic acid solution at water-bath temperature, this compound gave 2 : 4 : 6-tribromoaniline, m. p. 119°.

3 : 5-*Dibromohydrazobenzene*.—5 G. of 3 : 5-dibromoazobenzene in 250 c.c. of alcohol were refluxed for 2 hours with 8·5 g. of stannous chloride and 10 g. of sodium hydroxide, also dissolved in 250 c.c. of alcohol. The alcohol was partly removed, the residue poured into water, and the product extracted with ether. It separated from light petroleum (b. p. 60—70°) in small plates, m. p. 114° (Found: Br, 46·7. $C_{12}H_{10}N_2Br_2$ requires Br, 46·75%).

2 : 6-*Dibromobenzidine* was obtained when (*a*) 3 : 5-dibromoazobenzene was reduced with stannous chloride in alcoholic hydrochloric acid solution; and (*b*) 3 : 5-dibromohydrazobenzene was refluxed with an excess of concentrated hydrochloric acid for 30 minutes. It crystallised from dilute alcohol in needles, m. p. 185° (Found: Br, 46·8. $C_{12}H_{10}N_2Br_2$ requires Br, 46·75%).

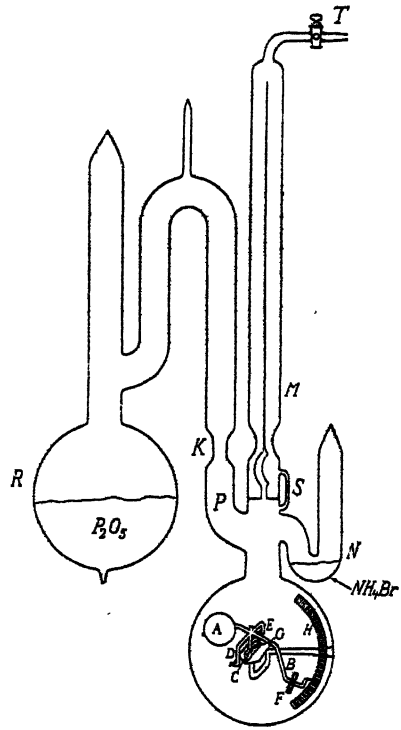
CCCLXXXVI.—*Determination of the Pressure and Density of Moist, Saturated Ammonium Bromide Vapour.*

By ANDREAS SMITS and RONALD PURCELL.

THIS investigation originated in the intention to apply the densitensimeter (this vol., p. 2409) to a study of the influence of intensive drying on the vapour pressure and density of ammonium bromide. The moist material was first reinvestigated in this apparatus, which enables the pressure and density to be determined simultaneously, and thus avoids a source of error occurring in experiments where the pressure is measured first and the density subsequently in a separate apparatus. For example, the method used by Smith and Lombard

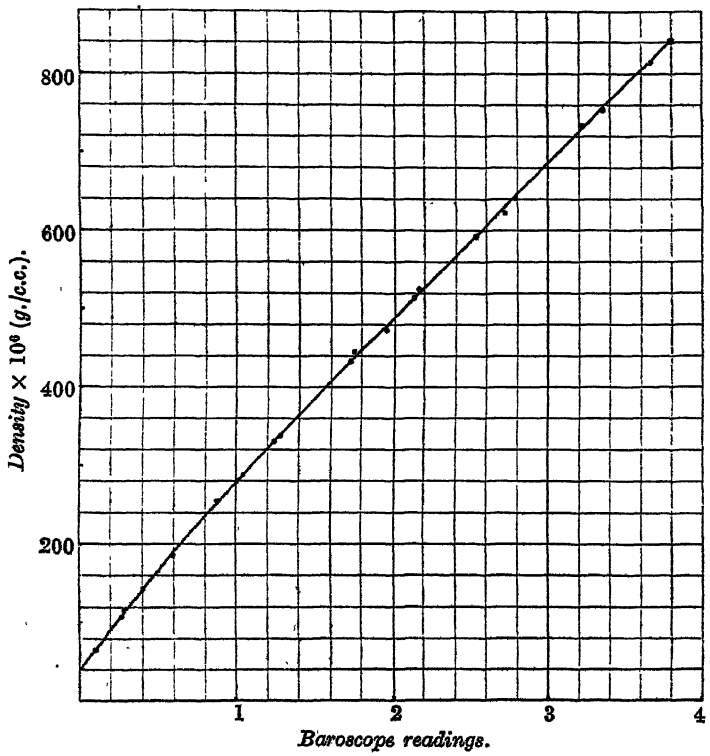


(*J. Amer. Chem. Soc.*, 1915, **37**, 38) is open to criticism unless it is certain that the large bulb, B (Fig. 1), was never at a lower temperature than the small one, A, while the apparatus was attaining the temperature of the bath; but since, in order to hold the apparatus firmly in the bath, the bulb was wired to an iron rod protected with asbestos paper, it is probable that when the capillary, D, was sealed some solid as well as vapour was in the bulb B. Any adsorption of vapour on the walls will introduce an error in the same direction, *i.e.*, giving too high a vapour density.

FIG. 1.

With the densi-tensimeter, it is possible to prevent solid being deposited on the surface of the baroscope by taking readings after the apparatus is cooled from a higher to a lower temperature. During the cooling, the silica baroscope is a little warmer than the outer glass wall of the flask, and consequently all salt sublimes on to the latter. Moreover, the newest baroscopes are so constructed that the error caused by adsorption is negligible.

FIG. 2.



EXPERIMENTAL.

Fig. 2 shows the bulb containing the baroscope sealed to the glass-spring indicator. The figure also shows, however, a bulb with phosphoric oxide, which was not present in these experiments with the moist substance—in this case tube P was sealed off at K. This apparatus was cleaned with boiling nitric–chromic acid mixture, washed, steamed, and dried. The baroscope was then calibrated at 100°, 306°, and 394° by altering the pressure of the air in the instrument and reading the position of the pointer of the baroscope. The densities (g./c.c.) of the air was then calculated and plotted against the baroscope readings, thus giving a calibration curve (see Table I and

FIG. 3.

After calibration, the apparatus was heated to near the softening point of the glass in a stream of dry oxygen. The ammonium bromide was introduced into the bend of the tube N (Fig. 2), which was then resealed, and the apparatus connected to the high-vacuum pump through tap T. After exhaustion, this tap was closed, and the thin tube, S (called the bridge), sealed off. The apparatus was placed vertically, and the zero position of the glass-spring indicator ascertained in the usual manner.

The apparatus was then placed in a bath of fused potassium and sodium nitrates contained in a 4-litre Pyrex-glass beaker. With suitable illumination, the position of the needle of the baroscope could be read with the aid of a small telescope. The beaker was placed over a large double-ring gas burner and surrounded by an asbestos hood, in which two holes were made to permit baroscope readings to be taken. Two large Bunsen burners, for regulation of the temperature, also passed through this hood.

The top of the hood was covered with asbestos board, through which passed the mantle of the densi-tensimeter, a resistance thermometer, and a stirrer. It was possible to detect a change of 0·005° with the thermometer, and the bath could be readily kept constant to within 0·1° during a reading by means of a specially designed stirrer with ball bearings, which was driven at 800 r.p.m. A number of simultaneous readings of the vapour pressure (p in cm. Hg) and baroscope positions were then made at temperatures between 330° and 400°. The results of these are given in Table II. The densities, d, were read from the calibration curve, and the vapour densities, $D(= \frac{1}{2}M)$, calculated from this, on the assumption that the gas laws were obeyed :

$$D = 22{\cdot}4 \times d \times T \times 760/(2 \times 273 \times p).$$

When $\log p$ is plotted against $1/T$ (the reciprocal of the absolute temperature), the points on Fig. 4 are obtained. It will be seen that they lie on a straight line, thus showing that the heat of evaporation is not a function of temperature within the range investigated. This result is in agreement with the values of the densities in the last column, which correspond closely with complete dissociation, the calculated value being 24·5. It will be noticed, however, that the values found are even lower than this. An error in this direction will be introduced if there is any adsorption on the bulb of the baroscope, and, as shown later, there is sufficient

tion to give such an error, but when this is eliminated, the result corresponds exactly with complete dissociation.

The above results are represented graphically in Fig. 5, where the vapour pressures are plotted against the temperature, the determinations by Smith and Calvert (*J. Amer. Chem. Soc.*, 1914, **36**, 1368) and by Johnson (*Z. physikal. Chem.*, 1908, **56**, 39) being inserted for reference. It will be noted that our values are slightly below those of the earlier workers. The vapour densities have been determined by Deville and Troost and by Smith and Lombard (*loc. cit.*). The former found complete dissociation at 440° and 860°, whilst the latter found a *change from* 48% *dissociation at* 300° *to* 10% *at* 390°. The measurements of Smith and his coworkers would seem to be beyond criticism, but closer consideration shows that an error must have been introduced, for when the logarithms of their vapour pressures are plotted against $1/T$ a straight line is obtained (see Fig. 4). This indicates that the heat of evaporation is *not* a temperature function, and hence that the degree of dissociation cannot change appreciably unless the heat of dissociation is very small; but since this is known not to be the case, most probably the dissociation is complete. Hence it was thought that Smith and Lombard's density determinations were incorrect, and an independent method of checking the results was sought.

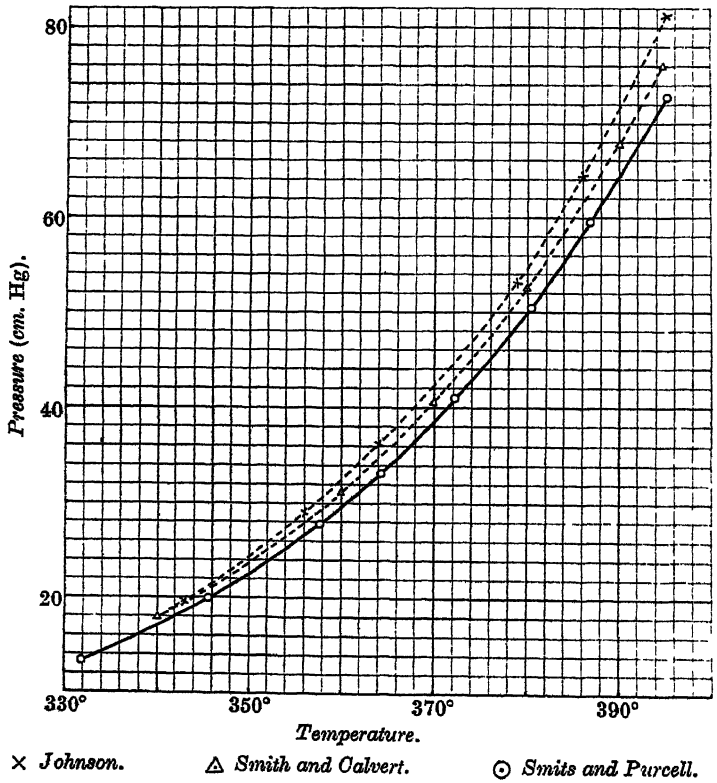

FIG. 4.

We therefore determined the vapour density in yet another

way, namely, by what we called the "extrapolation method." A vapour-pressure apparatus of known volume was filled with a known weight of ammonium bromide, highly evacuated, and the bridge sealed off. The vapour density could be determined by measuring first the pressure curve of the saturated vapour and then the Boyle–Gay-Lussac line or the curve of the unsaturated vapour, since, from the point of intersection of the lines obtained by plotting

FIG. 5.

log p against $1/T$, the vapour density of the just-saturated vapour is readily calculated. Table III gives the results obtained with a glass apparatus and two other experiments with glass and quartz apparatus gave similar results. These three experiments carried out in this manner, with an apparatus of Durobax glass and quartz, g[illegible] the results in Table IV, in which the pressure and temperature[illegible] to the points of intersection. These points had to be [illegible] extending the two lines mentioned above, since experim[illegible]

did not find an intersection but a continuous change of one line into the other (see Fig. 6).

This remarkable fact proves that there is a perceptible adsorption, caused by the glass wall. So long as there is an excess of solid substance, this adsorption does not exert any influence on the vapour pressure, but when the solid substance has apparently just disappeared there is still a small quantity adsorbed by the wall of the vessel, which is gradually liberated at higher temperatures. The effect is that with rising temperature the curve of the saturated vapour pressures is left at too low a temperature and the Boyle–Gay-Lussac

line is reached at too high a temperature. Between these two the pressure is abnormally low. Both glass and quartz behaved in the same way. This phenomenon, which has also been found with mercuric iodide (Rinse, this vol., p. 1442), interested us, since it explained the slightly low values of vapour densities determined with our baroscope. The adsorption per sq. cm. of silica surface of the apparatus can be calculated, and from this result we find that the weight of adsorbed material on the baroscope is just sufficient to account for the low values. Though the differences are rather small, Smits thought it advisable to change the construction of the baroscope once more, in order to eliminate the error, and this was effected by having equal silica surfaces on each side (this vol., p. 2410).

Finally, the value of the heat of evaporation can be calculated from our results. From the formula, $d \log_e p/dT = Q/RT^2$, it follows that $d \log_e p/d\left(\frac{1}{T}\right) = Q/R$. Now it has been shown that $\log_{10} p$ is a linear function of $1/T$, which proves that Q is not a temperature function. In agreement with this, the vapour-density determinations showed that the dissociation of ammonium bromide in the vapour state from 330—400° is complete. Consequently we can write $2{\cdot}303 \log_{10} p = -Q/RT + C$. From Fig. 4, using Briggsian logarithms, we read,

for $1/T_1 = 0{\cdot}001651$, $\log_{10} p_1 = 1{\cdot}1271$,

and for $1/T_2 = 0{\cdot}001497$, $\log_{10} p_2 = 1{\cdot}8613$,

hence $$Q/R = \frac{2{\cdot}303(1{\cdot}8613 - 1{\cdot}1271)}{1651 \times 10^{-6} - 1497 \times 10^{-6}} = 10980$$

or $Q = 22 \times 10^3$ cals. This value refers to 1 g.-mol. of vapour, and since the salt is completely dissociated, it corresponds to 1/2 g.-mol. of ammonium bromide; thus $(Q_{SG})_{NH_4Br} = 44 \times 10^3$ cals. The value given by Johnson, *viz.*, $45{\cdot}4 \times 10^3$ cals., differs somewhat from this.

The value of C follows from

$$C = \frac{2{\cdot}303(T_2 \log p_2 - T_1 \log p_1)}{T_2 - T_1} = 20{\cdot}8$$

so that $$\log_e p = -\frac{10980}{T} + 20{\cdot}8.$$

Summary.

Using a new apparatus, the " densi-tensimeter " (see Smits, this vol., p. 2409), we have measured simultaneously the vapour pressures and vapour densities of ammonium bromide. When $\log p$ is plotted against $1/T$, a straight line was obtained, from which it follows that the latent heat of evaporation between 300° and

not a function of temperature. This result indicated that most probably the vapour would be completely dissociated, and the density determinations with the baroscope showed, in fact, a total dissociation.

The cause of the discrepancy between this result and that of Smith and his co-workers is discussed, and a possible source of error in their work is indicated.

In order to check the density determinations, the authors applied the "extrapolation method," measuring the pressure of the saturated and of the unsaturated vapour of a weighed quantity of salt in a known volume. The plot of log p against $1/T$ gave two straight lines, and when these were produced, their point of intersection gave the pressure and temperature of the just-saturated vapour, from which it was calculated that the corresponding vapour density agreed with complete dissociation.

The two straight lines did not actually intersect, however, but curved and merged into one another, thus indicating a perceptible adsorption on the wall of the apparatus.

Calculation indicated that if the baroscope reading was corrected for this adsorption the result agreed with that obtained by the second method.

The heat of evaporation of ammonium bromide was calculated from the experimental data and found to be 44,000 cals.

THE UNIVERSITY, AMSTERDAM. [*Received, July 13th*, 1928.]

CCCLXXXVII.—*Determination of the Pressure and Density of Moist, Saturated Ammonium Chloride Vapour.*

By ANDREAS SMITS and WILHELMUS DE LANGE.

IN the course of our study of the influence of intensive drying on the pressure and density of saturated ammonium chloride vapour by means of the densi-tensimeter (this vol., p. 2409), we required, as in the case of ammonium bromide (Smits and Purcell, preceding paper), accurate data for the moist material, and as Braune and Knoke (*Z. physikal. Chem.*, 1928, **135**, 49) have recently described experiments on this subject, we thought it desirable to publish this part of our study at once.

For the solution of the "ammonium chloride problem," it was necessary to determine the vapour pressure of the solid and the density of the saturated vapour simultaneously, and this is rendered possible by our densi-tensimeter. In previous determinations of

the density of the saturated vapour, the vapour pressure of the solid was measured first, and the density was subsequently found either by sealing off a bulb of the same apparatus (Johnson, *ibid.*, 1908, **61**, 457), or by use of a separate apparatus, care being taken that the apparatus was filled with the saturated vapour (Smith and Lombard, *J. Amer. Chem. Soc.*, 1915, **37**, 38). As already explained (Smits and Purcell, *loc. cit.*), however, the possibilities of error in such determinations are considerable, for the density bulb which must be sealed off may never have been at a lower temperature than the bulb with the solid ammonium chloride. Johnson intentionally kept the density bulb at a slightly higher temperature than the solid substance. On the other hand, Smith and Lombard wished to determine the density of the completely saturated vapour, and therefore tried to keep the bulb containing solid ammonium chloride and the density bulb at exactly the same temperature; Smits and Purcell, however, adduced a reason why these authors did not succeed in the case of ammonium bromide, and it is now shown that their results for ammonium chloride also are incorrect, probably for a similar reason. Braune and Knoke tried to avoid the difficulty. They first determined the pressure of the saturated vapour in an apparatus of known volume, and after the solid substance had disappeared and the vapour had become unsaturated, they continued the pressure reading at different temperatures. Then all the salt was condensed in a bulb which was sealed off, and the quantity of salt was thus determined. They therefore found the density of almost saturated and of less saturated vapour.*

Our purpose was to find the density of the completely *saturated* vapour by the two different methods described by Smits and Purcell (*loc. cit.*).

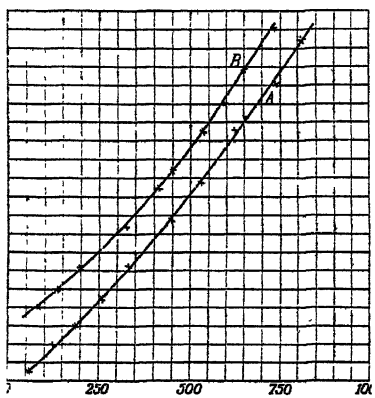
In the second method (the " extrapolation method "), it was shown that any error introduced by adsorption of vapour on the wall of the density bulb could be detected and an appropriate correction made in the density.

Experiments with the Densi-tensimeter.

We used two baroscopes, A and B, which correspond respectively to Figs. 2 and 3 given in the description of this apparatus (this vol., p. 2409), and the method by which they are sealed to the

* Braune and Knoke did not use the glass-spring indicator, the zero position of which, as we stated long ago, is independent of temperature, but they used a glass spiral, of which the position is influenced by temperature, so they were obliged to apply a correction.

The vapour pressures indicated in their tables as " Dissoziations " are much too low.



vapour-pressure apparatus with the glass-spring indicator is shown in the paper of Smits and Purcell (Fig. 2), where details of the method of using the apparatus are also to be found.

The two baroscopes were calibrated at different temperatures as already described. The data for baroscope A are those already given; those for B are in Table I, and the two calibration curves are shown in Fig. 1. The vapour densities are calculated from the densities (d; in g./c.c.) read from the calibration curves by the formula:

$$D = \tfrac{1}{2}M = 224 \times 76dT/2 \times 273p = 31{\cdot}18dT/p.$$

After the necessary preliminary operations, a number of simultaneous readings were made at temperatures between 254° and 353°. The densities were read from the calibration curve and the vapour densities calculated. A few of the results are shown in Table II, where p is given in cm. of mercury; the other points are included in Figs. 2 and 3. Both baroscopes give identical results, and since the theoretical value for complete dissociation is $\frac{1}{4} \times 53{\cdot}5 = 13{\cdot}4$, it follows that the saturated vapour in the temperature range 280—340° is completely dissociated.

FIG. 1.

When $\log p$ is plotted against $1/T$, the points marked ⊙ in Fig. 2 are obtained. These points lie on a straight line, which shows that Q_{sG} is not a temperature function within the range investigated. This result is in complete agreement with the density

determinations, corresponding with practically total dissociation. In Fig. 3 the vapour pressure is plotted against the temperature, again marked ⊙.

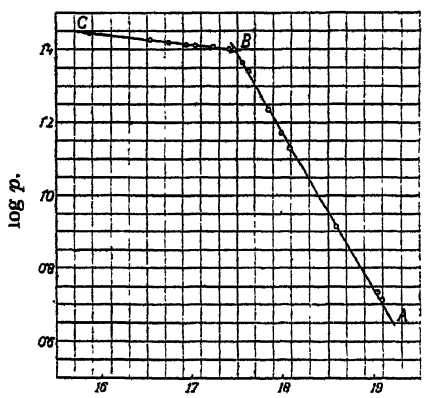
The extrapolation method for the determination of the

density was then used in order to find whether adsorption occurred, and if so, to what extent. A vapour-pressure apparatus of known

FIG. 3.

volume was therefore filled with a known weight of ammonium chloride, highly evacuated, and the bridge sealed off. The pressure

of the saturated vapour was measured first and then the Boyle–Gay-Lussac line, or the curve of the unsaturated vapour. The point of intersection of the lines obtained by plotting $\log p$ against $1/T$ enables the vapour density of the just-saturated vapour to be calculated.



Two series of experiments were carried out with a quartz-apparatus with both rising and falling temperatures, and readings were recorded only after the vapour pressure at any one temperature had been constant for an hour. The results are in Table III.

					252·3	525·3	1904	5·46	0·787

When $\log p$ is plotted against $1/T$, two straight lines (Fig. 4) are obtained; these intersect in a point such that $\log p = 1{\cdot}399$ and $1/T = 0{\cdot}001746$, *i.e.*, $p = 25{\cdot}06$ cm. and $T = 572{\cdot}7$. Since the volume of the apparatus was 314·7 c.c. and the weight of ammonium chloride 59·6 mg., the density is *13·4*, which is just the theoretical value for complete dissociation, whereas the densi-tensimeter gave *13·48*.

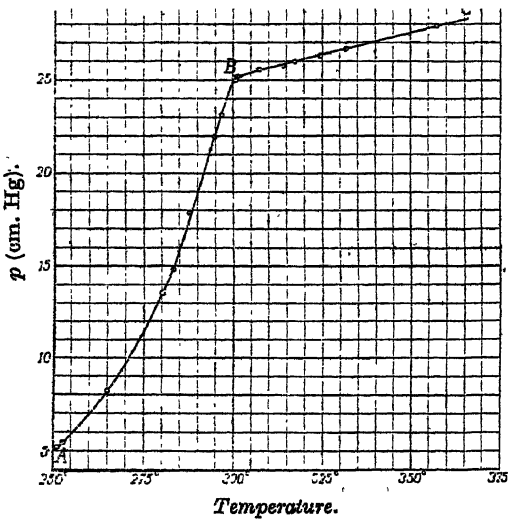

FIG. 4.

These determinations were also important in deciding whether there was any perceptible adsorption by the quartz wall, as in the case of ammonium bromide. From Fig. 4, and also from Fig. 5, in which p is plotted against temperature, it is seen that if a continuous change of one line into the other exists at all it can only occur over an exceedingly small range of temperature, and hence, unlike the bromide, ammonium chloride is not perceptibly adsorbed by the quartz wall, and the same remarks apply to glass. This explains why both forms of the beginning (A and B) gave exactly the same results (Table II).

The points derived from other workers' determinations of the vapour pressure have been inserted in Figs. 2 and 3. It will be noted that the values of Johnson are not very correct; those of Smith and Calvert (*J. Amer. Chem. Soc.*, 1914, **36**, 1363) and of Braune and Knoke are much better. If Smith and Calvert had plotted a curve as in Fig. 2, they would have found that their points lie on a straight line, and hence that the heat of evaporation is not a temperature function and the degree of dissociation could not change appreciably, unless the heat of dissociation were very small, which is known not to be the case. Consequently, before we

FIG. 5.

started our vapour-density determinations it was already almost certain that practically complete dissociation would be found. Smith and Lombard (*loc. cit.*), however, found a dissociation varying from 55·5 to 63·6% in the temperature range 280—333°.

Earlier workers, *viz.*, Deville and Troost (*Ann. Chim. Phys.*, 1860, **58**, 257; *Compt. rend.*, 1859, **49**, 242), Ramsay and Young (*Phil. Trans.*, 1886, **177**, 99), and Pullinger and Gardner (P., 1891, **7**, 2), applying respectively the methods of Dumas, Hofmann, and Victor Meyer, found degrees of dissociation of 82—98% between 280° and 400°, but Smith thought that the difference between these values and his own was due to the fact that most of the earlier determinations related to unsaturated vapour and that, in consequence of the slow evaporation, the Victor Meyer method did not give exact results, owing to diffusion before the reading could be taken.

Similarly, Smith contended that other high degrees of dissociation (*e.g.* 100% and 91% at 350°, Baker, J., 1894, **65**, 611; 95% at 380°, Gutmann, *Annalen*, 1898, **299**, 282; 98% at 322°, Johnson, *loc. cit.*) were due to the vapour being unsaturated in these cases also. Our determinations, carried out in two different ways, prove, however, that Smith and Lombard's density determinations must have been incorrect for reasons already given (Smits and Purcell, *loc. cit.*), and the measurements of Braune and Knoke, relating to vapours some of which were almost saturated, also indicated complete dissociation.*

Finally, the heat of evaporation and the constant C in the vapour-pressure formula $2{\cdot}303 \log_{10} p = -Q/RT + C$ can be calculated from our results by applying the methods used by Smits and Purcell (*loc. cit.*). From our graph we have

for $1/T_1 = 0{\cdot}001900$, $\log p_1 = 0{\cdot}735$,

and for $1/T_2 = 0{\cdot}001600$, $\log p_2 = 2{\cdot}025$;

hence $Q/R = 9903$, or $Q_{sc} = 19{\cdot}8 \times 10^3$ cals. This value refers to 1 g.-mol. of vapour, and since we have found that the vapour is completely dissociated, it corresponds to 0·5 g.-mol. of ammonium chloride, so the value for 1 g.-mol. is $(Q_{sc})_{NH_4Cl} = 39{\cdot}6 \times 10^3$ cals., whereas Johnson found $37{\cdot}8 \times 10^3$ cals. and Braune and Knoke $39{\cdot}4 \times 10^3$ cals.

Also, from the same data, $C = 20{\cdot}5$, and hence the vapour-pressure formula is

$$2{\cdot}303 \log_{10} p = -9903/T + 20{\cdot}5$$

whence the sublimation temperature (for $p = 76$) is $T = 612{\cdot}3°$ (339·3° C.).

Summary.

Using the latest form of the densi-tensimeter and also its immediate predecessor, the authors determined the pressures and densities of moist, saturated ammonium chloride vapour, as a preliminary to studying the influence of intensive drying on these properties.

Vapour-pressure determinations showed that the heat of sublimation is not a temperature function within the range 254—353°, and the density determinations give the explanation of this behaviour, for they show the dissociation of the saturated vapour to be practically complete over the same range of temperature. Similarly, complete dissociation was found by using the extrapolation method previously described.

* The remarks of Braune and Knoke about the explanation of the behaviour of intensely dried ammonium chloride are incorrect. Our results with the moist material do not affect that explanation at all.

The authors conclude that the results of Smith and his collaborators, giving dissociations of about 60%, must be incorrect—probably for the same reason that their results for the vapour density of ammonium bromide are incorrect. The results of Braune and Knoke are in agreement with those of the authors.

The molecular heat of sublimation for 1 g.-mol. of ammonium chloride is calculated to be $39{\cdot}6 \times 10^3$ cals., and from the derived vapour-pressure formula the sublimation temperature is calculated as 339·3°.

THE UNIVERSITY, AMSTERDAM. [*Received, September 7th*, 1928.]

CCCLXXXVIII.—*Adsorption of Vapour on a Quartz or a Glass Wall.*

By ANDREAS SMITS.

SMITS and PURCELL (this vol., p. 2941) have shown that their "extrapolation method" enables one to find, not only the vapour density of the saturated vapour, but also the extent of adsorption by the walls of the apparatus. In the case of ammonium bromide, the change of the vapour-pressure curve of the saturated vapour into that of the unsaturated vapour (Boyle–Gay-Lussac curve) was not sharp, but took place over a temperature range of several degrees, *i.e.*, the saturated vapour-pressure curve was left at too low a temperature, and the Boyle–Gay-Lussac line was reached at too high a temperature. This continuous curve was found with both rising and falling temperatures, so there is no doubt as to its reality. Both quartz and Jena glass apparatus were used, and in order to keep the wall as smooth as possible, the apparatus had not been allowed to come into contact with water or water vapour.

These experiments were of great interest, since the results of McHaffie and Lenher (J., 1925, **127**, 1559) and of Lenher (J., 1926, 1785; 1927, 272) on the adsorption of water and benzene vapour on glass, silica, and platinum surfaces at temperatures near the saturation temperature had been criticised by Fraser, Patrick, and Smith (*J. Physical Chem.*, 1927, **31**, 897) on the ground that the walls of the apparatus were not plane, but had been etched by acid-cleaning. These authors had observed that for water and toluene the smoothness of the surface was very important, and that no adsorption of toluene on a plane surface could be detected by vapour-pressure determinations. At the time of publication of Fraser, Patrick, and Smith's paper, Rinse was completing investigations (this vol., p. 1442) in the author's laboratory which showed

that mercuric iodide was adsorbed in layers 500 molecules thick at 300°, even though the glass walls had been kept as smooth as possible and had not been in contact with water or water vapour. Still more recently, J. W. Smith (this vol., p. 2045) has shown that a platinum vessel, of which the walls had been amalgamated in order to render them as plane as possible, adsorbs molecular layers, the number of which increases as the saturation temperature is approached: within the range of 30° the maximum number of adsorbed molecular layers was 40 in the case of water and 300 in the case of benzene. Further, de Boer (*Physica*, 1928, **8**, 145) has found that even at room temperature 30 molecular layers of iodine are adsorbed on calcium fluoride, and if it had been possible to approach the saturation temperature more closely, this number would probably have been much higher.

The author's application of the extrapolation method to find the degree of adsorption by the glass wall has been mentioned (Smits and Purcell, this vol., p. 2943) but not yet described. In the paper quoted, Fig. 6 shows the continuous change of the saturated into the unsaturated vapour-pressure curve, and on extrapolation the two lines intersect at a point corresponding to 379° and 49 cm. Hg. The vapour pressure measured at this temperature was, however, 48 cm. Hg, *i.e.*, 1 cm. too low. The bulb of the apparatus had a radius of 5·25 cm., so the surface was 346·36 cm.^{2}, or say 350 cm.^{2}. The bulb contained 0·3404 g. of ammonium bromide, so the decrease of 1 cm. in the vapour pressure corresponded with 0·0068 g., *i.e.*, the number of adsorbed molecules is $4{\cdot}23 \times 10^{19}$. From *X*-ray investigations on ammonium bromide it follows that in a crystal layer a molecule has a cross section of 25×10^{-16} cm.^{2}. On a surface of 350 cm.^{2}, therefore, 14×10^{16} molecules can be arranged in one layer, but since $4{\cdot}23 \times 10^{19}$ molecules were adsorbed, the number of adsorbed molecular layers would be 300. This result is very remarkable and of the same order as that obtained by Rinse and by Smith.

Although this phenomenon is being further investigated in this laboratory with various surfaces and substances, the following points may already be emphasised. Suppose we have a bulb containing a liquid or a solid volatile substance, and adsorption occurs on the wall of the vessel, which is a general phenomenon; the system wall + adsorption layer will then be a part of the whole equilibrium system. Equilibrium cannot be established before the glass wall has adsorbed so many molecular layers that the vapour pressure of the "wall-phase" (as we may call it) is the same as that of the solid or liquid phase in the bulb. Now, the [illegible] experiments seem to show that, depending of course on the nature

of the substance, the wall-phase can consist of a large number of molecular layers, and if we accept this conclusion, the following considerations arise.

On increasing the temperature to the stage at which the last part of the solid or liquid phase has just disappeared, the wall-phase will still have a pressure equal to that of the saturated vapour at that temperature. Further increase of temperature causes the number of adsorbed molecular layers to become smaller and smaller. If the solid or liquid phase had still been present, the number of adsorbed molecular layers would have increased, so that now, the solid (or liquid) phase having disappeared, the number of adsorbed molecular layers is too small to give a pressure equal to that of the saturated vapour at the same temperature. The wall-phase will consequently give a lower vapour pressure, and the deficiency will increase continuously with rising temperature.

Finally, the wall-phase disappears, leaving behind probably a unimolecular layer, and the Boyle–Gay-Lussac line is practically reached.

Summary.

It is shown that experiments of other investigators and also of the author indicate that the adsorption films on a mercury surface and on glass or quartz surfaces, as plane as possible, formed in almost saturated vapour, can consist of a large number of molecular layers.

THE UNIVERSITY, AMSTERDAM. [*Received, September 14th*, 1928.]

CCCLXXXIX.—*A Phase Rule Investigation of Cupric Bromide in Aqueous and Hydrobromic Acid Solutions.*

By SYDNEY RAYMOND CARTER and NORMAN JOSEPH LANE MEGSON.

APART from the desirability of acquiring accurate data for the solubility of copper bromide, a number of interesting problems arise concerning its hydrates and hydrobromides, as well as the remarkable colour effects which are observed in hydrobromic acid solutions containing cupric salts. From its heat of formation, Bodländer (*Z. physikal. Chem.*, 1898, 27, 61) has calculated the solubility of cupric bromide in water as 1·3 equivs. per litre, but this value, which presumably refers to ordinary temperatures, is necessarily only approximate and has not yet been verified.

The salt is known in the anhydrous form and as a tetrahydrate,

the former being obtained by evaporation of solutions on the water-bath, and the latter crystallising as green needles from solutions at about 0°; Kurnakow and Sementschenko (*Z. anorg. Chem.*, 1899, **19**, 337) give 29·0—30·5° as the transition temperature of the system. The tetrahydrate has no analogue in cupric chloride, the stable variety of which is $CuCl_2,2H_2O$. Löwig ("Das Brom und seine chemischen Verhältnisse," 1829) is said to have obtained $CuBr_2,2H_2O$ by evaporation of solutions of cupric bromide, but Berthemot (*Ann. Chim. Phys.*, 1830, **44**, 386), although usually credited with preparing greenish-yellow needles of the same salt, gives no analyses.

Cupric bromide gives a deep violet coloration with hydrogen bromide, which is attributed by Sabatier (*Compt. rend.*, 1894, **118**, 1260) to a hydrated hydrobromide; he prepared this salt in an unstable condition by passing hydrogen bromide into saturated cupric bromide solution, and although analysis gave $3CuBr_2,2HBr,6H_2O$, he considered that, owing to instability, it was really represented by $CuBr_2,HBr,2H_2O$. Dilution tended to destroy the colour, but if the dilution had not been carried too far heating restored it.

Other bromides (*e.g.*, those of potassium, sodium, calcium, and especially lithium) also give this colour with cupric bromide, and Kurnakow and Sementschenko (*loc. cit.*) have isolated a compound $CuBr_2,2LiBr,6H_2O$. Moreover, cupric chloride and sulphate give a similar colour reaction with hydrobromic acid.

Weinland and Knöll (*Z. anorg. Chem.*, 1905, **44**, 116) prepared black, hygroscopic needles, to which they assigned the formula $CuBr_2,HBr,10H_2O$, by leaving a solution of cupric bromide in 40% hydrobromic acid in contact with the product of the action of hydrogen bromide on molybdenum trioxide; if the molybdenum compound was omitted, cupric bromide was the sole product.

Since Foote (*J. Amer. Chem. Soc.*, 1923, **45**, 663), from a study of the system cupric chloride–hydrogen chloride–water, had found $CuCl_2,2H_2O$ to be the only stable solid phase at 25°, whereas at 0°, in high concentrations of acid, the compound $CuCl_2,HCl,3H_2O$ existed in addition, we undertook a similar study of the bromine analogues in order to gain information on the various points raised in the foregoing discussion.

Experimental.

Materials.—Cupric bromide was used in the anhydrous form, but since it was liable to contain a small percentage of cuprous bromide, it was purified by oxidation with hydrogen peroxide, or by recrystallisation.

The hydrobromic acid for the weaker solutions was approximately

6*N*; frequently, however, higher concentrations were required, in which case the gas was prepared by the action of bromine on a solution of naphthalene in xylene (Kastle and Bullock, *Amer. Chem. J.*, 1896, **18**, 105) and purified by red phosphorus suspended in concentrated hydrobromic acid. The purity of the gas was tested by repetition with it of several solubility determinations already obtained by the use of the aqueous hydrobromic acid, and in all cases identical results were obtained.

Analytical Methods.—Copper was estimated volumetrically by titanous chloride, standard ferric alum and a large excess of 10% potassium thiocyanate being used as indicator. The latter contained hydrochloric acid (about 1*N*) to stabilise the cupric and ferric thiocyanates formed, as recommended by Emmett (J., 1927, 2059). Bromide was estimated by Volhard's method. Estimations of the radicals in trustworthy specimens of cupric bromide were quite concordant, and showed that these methods were accurate to within 1 part in 300 or 400 parts.

Solubility Apparatus.—In view of the high solubility of cupric bromide in water, it was desirable to use fairly small quantities of solution. Accordingly, a solubility vessel was devised in which the lower portion was narrow (2·5 cm. diameter; capacity 40 c.c.), whilst the neck was wide enough to take a rubber bung carrying a mercury-sealed stirrer and a sliding glass stopper. A small glass cup was sealed on to the shaft of the stirrer to prevent ground glass and vaseline lubricant falling into the mixtures.

The sliding stopper was used for inserting a tube for the removal of the liquid-phase samples through small sintered-glass filters, into either a pipette or a weighing bottle. The collecting apparatus was suitably water-jacketed at the appropriate temperature when necessary. An approximate density determination of the liquid was obtained at this stage by collecting a further sample in a small pyknometer having a capacity of about 1·0 c.c. The solid phase was finally examined by draining away the remaining liquid and removing a specimen of the moist solid by a flattened glass spatula. The solubility mixtures were usually stirred for 7—8 hours, and this period was shown to be ample for the attainment of equilibrium.

The System $CuBr_2$–H_2O.

Solubility determinations (Table I) were made at a series of temperatures ranging from 0° to 50°, the solid phase being examined in each experiment. The results are stated as g. of anhydrous $CuBr_2$ per 100 g. of solution, and are shown graphically in Fig. 1.

Examination of these figures in conjunction with the graph shows two features of interest. (1) First, the solubility of cupric

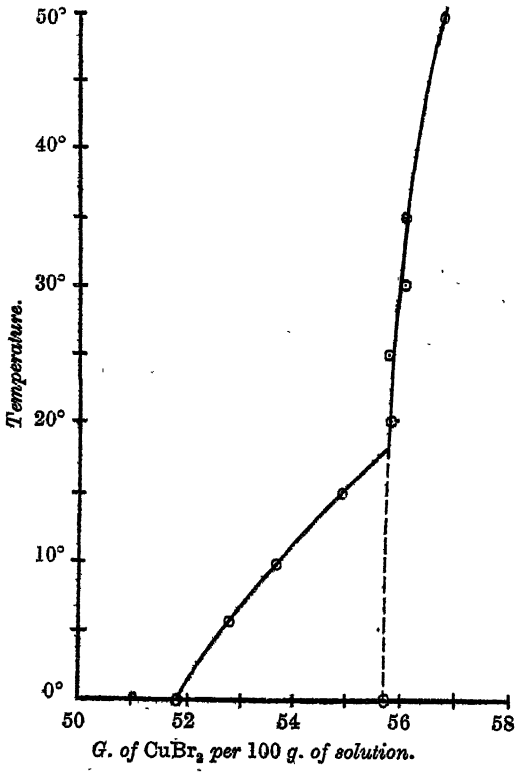

TABLE I.

Temp.	$CuBr_2$, %.	Appearance of solid phase.	Temp.	$CuBr_2$, %.	Appearance of solid phase.
0·0°	51·8	Green needles in deep brown liquid.	20·0°	55·9	Black rhomboids in deep brown liquid.

			50·0	56·8	
			(*Metastable state*)		
			0·0	*55·7	

* This value was obtained by stirring only a slight excess of cupric bromide with water for 5½ hours at 0°, a supersaturated solution being produced.

bromide is considerably greater than the value given by Bodländer (*loc. cit.*): the saturated solution has $d_4^{25°}$ 1·84 (see below), giving the solubility of the anhydrous salt as 1030 g. or 9·2 g.-equivs. per litre. (2) Secondly, there is a distinct break in the curve between 15° and 20°, indicating some change in the solid phase present, and corresponding with the difference in crystalline form noticed under the microscope (see Table I).

FIG. 1.

It was considered that the green needles represented the tetrahydrate described by several workers (*e.g.*, Sabatier, *Bull. Soc. chim.*, 1894, **11**, 677). This was confirmed by draining and drying a sample as rapidly as possible at a low temperature. It was a bright olive-green solid (Found: $CuBr_2$, 75·85. Calc. for $CuBr_2,4H_2O$: 75·63%), darkening on keeping for a few days at room temperature.

On drying a sample of the black rhomboidal crystals on a porcelain tile and filter paper at room temperature, a solid was obtained

apparently identical with the anhydrous cupric bromide (Found : $CuBr_2$, 99·9%). The lower portion of the curve therefore represents the solubility of $CuBr_2,4H_2O$ in water, whilst the upper portion gives the solubility of anhydrous $CuBr_2$. The latter is peculiar in that it has little or no temperature coefficient over the ranges 0—18—25°, and only a slight positive one from 35° to 50°.

The break in the curve at 18·0° obviously corresponds to the transition temperature of the hydrated salt; since this value is about 12° below that given by Kurnakow and Sementschenko (*loc. cit.*), various methods were adopted to substantiate it.

The Transition Temperature of $CuBr_2,4H_2O \rightleftharpoons CuBr_2 + 4H_2O$.

Experiments with the dilatometer indicated that the transition temperature lay between 21° and 14°, but owing to considerable supercooling, the method was unsuitable for more exact values.

A thermometric method gave more information, since the heating and cooling curves exhibited breaks at 19·8° and 16·2°, respectively, indicating a transition temperature of approximately 18°. Several difficulties prevented this determination from being completely successful, however, the chief being the consistency of the solid, which rendered efficient stirring almost impossible.

A more accurate value was obtained by using a modification of the thermometric method, due to Richards (*Z. physikal. Chem.*, 1898, **26**, 690). A specimen of the tetrahydrate was prepared by intimately mixing 12 g. of the recrystallised salt with the theoretical amount of water (4 g.) and cooling the mass in ice with continuous stirring until it became nearly solid. The mixture was drained on porous plate, and allowed to dry in a closed vessel below 10°. The hard green cake so produced showed the characteristic green needles of the tetrahydrate under the microscope, and since analysis indicated almost 100% of that salt, it was used without further purification.

About 12 g. of this salt were introduced into a test-tube fitted with thermometer and glass stirrer, and contained in a wider tube, leaving an annular air space of about 3 mm. The whole was placed in a water-bath at 19·5°, and the inner tube removed and dipped in the warm water until partial melting of the contents occurred; it was then wiped dry, replaced in the jacket, and allowed to stand in the bath. On stirring, the temperature of the mixture fell from 18·5° to 17·97°, where it remained constant for 45 minutes. It then rose slowly to 18·08° after falling to 17·90°, and finally fell with the temperature of the outer bath. The value 17·97° was therefore taken as the transition temperature of the system.

No evidence was found to support the existence of $CuBr_2,2H_2O$ either microscopically or from an examination of the solubility curve. The published analyses of this substance by previous authors were possibly carried out on samples of $CuBr_2,4H_2O$ which had effloresced.

The System $CuBr_2$–HBr–H_2O *at* 25°.

This system was investigated in the hope of elucidating the constitution of the compound prepared by Sabatier (*Compt. rend.*, 1894, **118**, 1260), and also of obtaining some evidence as to the cause of the violet colour produced by strong hydrobromic acid solutions and copper salts.

Various mixtures of hydrogen bromide in water were stirred with cupric bromide for 7—8 hours in the solubility bottle at 25°, and samples of the liquid phase and of the moist solid were then collected and analysed, the results being given in Table II and plotted

TABLE II.

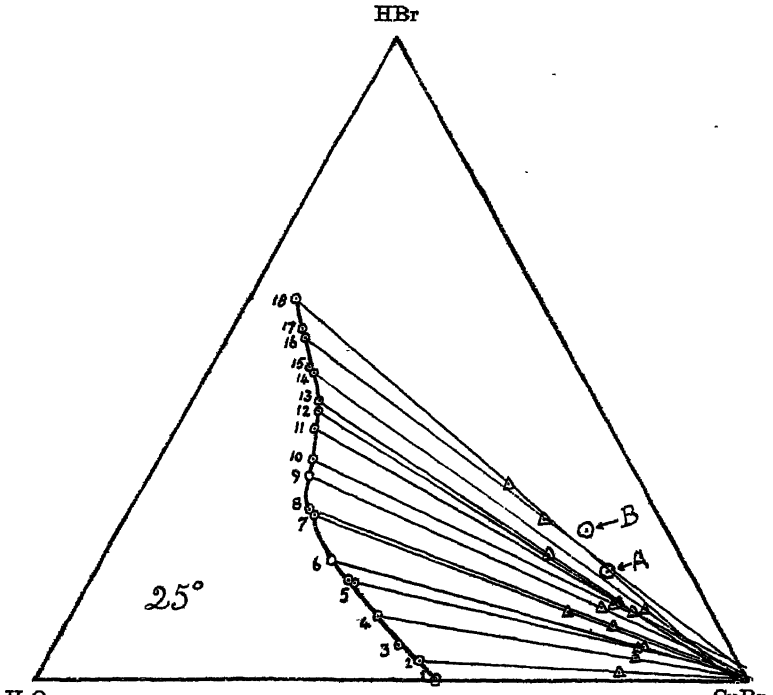
† Under the microscope the solid phase appeared as rhomboids mixed with much amorphous solid.



‡ Under the microscope the solid phase appeared as small, black, non-crystalline particles.

graphically in Fig. 2. From the compositions of the moist residues those of the pure solid phases were deduced by Schreinemakers's

method (*Z. physikal. Chem.*, 1893, **11**, 76), and the experimental values all pointed consistently to anhydrous cupric bromide as the solid in equilibrium throughout the whole range of acid solutions.

In order to obtain solubilities in high concentrations of acid, a saturated solution of hydrogen bromide at 25° was prepared by the method previously described. Attempts were made to move still further along the curve by passing hydrogen bromide into various

FIG. 2.

A = $3CuBr_2,2HBr,6H_2O$. B = $CuBr_2,HBr,2H_2O$.

solutions of aqueous cupric bromide, but these were only successful in special circumstances. When these high concentrations of acid were being dealt with, much fuming took place, and as a precaution, water was initially placed in both weighing bottles to prevent loss of the gas from the samples of phases extracted.

The solubility of the cupric bromide is seen to diminish with increasing concentrations of hydrobromic acid, falling from 55·8% to 7·7% with increase of acid from 0% to 59·3%. The solubility curve shows only one break (at Mixture 7), and the solid phase in equilibrium with the solution is in every case pure cupric bromide.

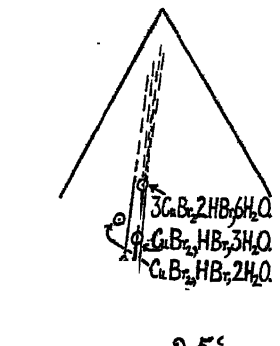
The latter fact had already been foreshadowed for low concentrations of acid by the results from the two-component system.

The density of the solution shows no marked break, but on the other hand has a definite minimum. It descends smoothly from 1·84 to 1·63, then rises regularly again to 1·83. Mixture 7, where the break in the curve occurs, in addition to possessing the minimum density of 1·63, has other important features of interest, first, in relation to the colour of the solution, and, secondly, in connexion with the form of the solid phase.

(1) When hydrogen bromide was introduced in small quantities into the deep brown saturated solution of the copper salt, a violet tinge was imparted to the solution, gradually increasing in intensity with rise in concentration and masking the brown colour. When the concentration of the acid indicated by Mixture 7 was reached, all traces of brown disappeared, and the solution assumed a bright violet colour, which persisted in an intensified degree with increase of acid. In thick layers, these solutions were almost opaque.

(2) Microscopic examination of the solid phase at low concentrations of hydrogen bromide showed black, rhomboidal crystals in a brown or violet-brown solution. These persisted in concentrations of acid up to 26% (Mixture 7) and to a small extent to Mixture 8, after which no definite crystalline form for the solid could be obtained, in spite of many attempts.

Since, throughout the curve, the stable solid phase is anhydrous cupric bromide, it seems probable that the break at Mixture 7 must correspond to a change in the form of that salt. For convenience, these two forms may be designated α-$CuBr_2$ and β-$CuBr_2$, the former being crystalline, and the latter existing in a non-crystalline form in high concentrations of hydrobromic acid.



The Different Forms of Cupric Bromide and the Colours of their Solutions.—It will be noted that the ranges of existence of the brown and of the violet-coloured solutions coincide approximately with the ranges of existence of the α- and β-salts respectively, and it might be thought that the violet coloration is associated in some way with the β-form. The coincidence may be merely accidental, but, on the other hand, it is well known that a change in the solid phase leads to a distinct change in the physical properties of the saturated solution in equilibrium with it. There are very few data in other systems to test whether this principle holds in the case of modifications of the same substance with regard to the colour of their solutions, but it may be mentioned that the various acid ferric phosphates are associated with solutions having different colours (J., 1923, **123**, 2231).

The changes in colour which salt solutions undergo as the [illegible]

of alteration of temperature or the addition of acids or other salts have been extensively studied by Donnan, Sidgwick, Ostwald, and others (for references, see J., 1910, **97**, 957), and they can usually be explained by considerations of hydration, ionisation, or complex formation.

The Possibility of Complexes of Cupric Bromide and Hydrogen Bromide.—Since one of our main objects was the investigation of the possible solid phases, we thought it of interest to seek evidence of complex acid salts which might exist in the solid state. Examination of the solubility curve shows no indication of a stable solid phase having either of the formulæ put forward by Sabatier to represent the composition of the compound prepared by him (see points A and B, Fig. 2). An attempt was made to repeat his experiment of passing hydrogen bromide into a saturated solution of cupric bromide, and the mixture was allowed to cool before being stirred in the thermostat. A modification was also introduced by cooling the solution during the actual passage of the gas. In each case, after stirring for 7—8 hours, the points obtained lay on the solubility curves (14, 16, and 17) and had anhydrous cupric bromide as their stable solid phase.

FIG. 3.

Attempts were also made to obtain analyses before stirring, by draining samples of the solid immediately after preparation by the above method, in a closed vessel, until apparently dry. Very inconsistent results were obtained, varying from practically pure $CuBr_2$ to a compound having the formula $CuBr_2,HBr,3H_2O$. The substance seemed, therefore, both from its appearance while draining (during which it apparently lost water) and from the analysis, to be extremely unstable.

$$-HBr \quad H_2O \longrightarrow$$

Metastable Portion of System $CuBr_2$–HBr–H_2O *at* 25°.—Some determinations were carried out by stirring mixtures obtained as above for short periods of from 1—4 hours at 25° in the hope of gaining evidence of a complex solid phase before the latter had time to break up. Table III and Fig. 3 illustrate the results obtained in these circumstances, the solid phase appearing under the microscope as very irregular particles having slight and indefinite crystalline form.

TABLE III.

Mixture.	$d_{4^\circ}^{25^\circ}$.	Liquid phase.		Moist solid phase.	
		$CuBr_2$, %.	HBr, %.	$CuBr_2$, %.	HBr, %.
A.	1·81	15·3	49·5	52·6	27·9
B.	1·83	14·1	51·1	52·0	28·8
C.	1·83	13·0	52·4	—	—
D.	1·83	11·9	54·3	41·1	36·0
E.	1·83	11·5	55·3	46·7	32·9
F.	1·87	10·4	56·7	58·5	26·6

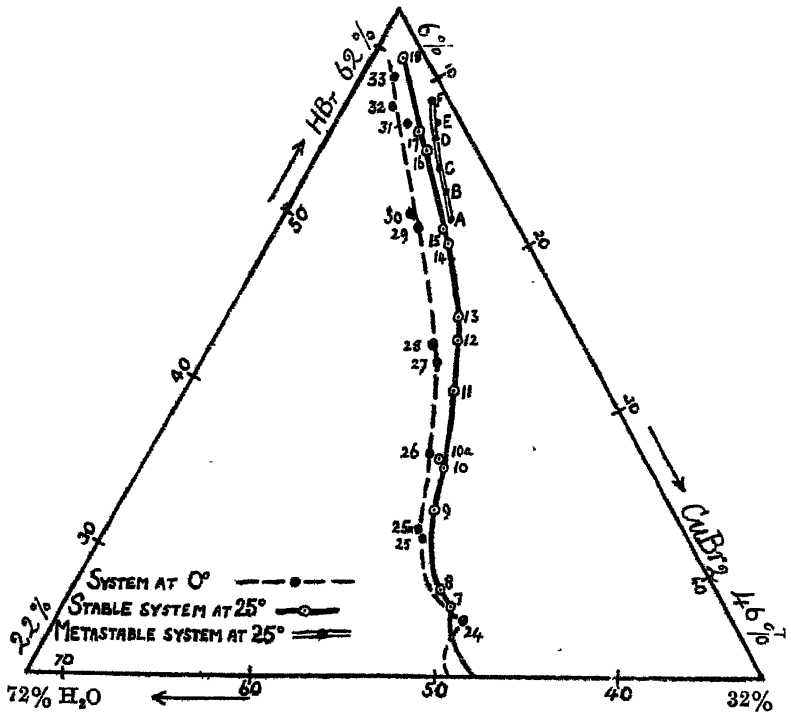
It will be seen from the figure that the tie-lines through the moist solid phases focus probably on the compound

$$3CuBr_2,2HBr,6H_2O.$$

The complex is certainly not $CuBr_2,HBr,2H_2O$, as suggested by Sabatier, although it is possibly $CuBr_2,HBr,3H_2O$; if this were so, it would correspond to the analogous compound, $CuCl_2,HCl,3H_2O$, described by Foote (*loc. cit.*). Evidence that one of the above formulæ really represents the composition of the solid phase is afforded by the fact that the moist solid phase gives points much farther from the apex of the triangle than do moist specimens of cupric bromide alone.

The mixtures themselves lie on a smooth curve, of which the relationship to the main curve (Fig. 2) will be seen from Fig. 4, where a portion of the triangular diagram is drawn to a larger scale; being on the right of the main curve, *i.e.*, nearer the solid phase, this curve must represent the more unstable form. In addition, from the position of the curve subsequently obtained at 0° (shown in Fig. 4), increase of temperature would appear to favour the stability of the compound, which was always destroyed after continued stirring for 7—8 hours at 25°, even in concentrated hydrobromic acid solution.

In this connexion it is of interest to notice that combination between cupric bromide and soluble bromides is already suspected to occur in solution, and the existence of the resulting complex ions has been detected by Denham by migration experiments (*Z. physikal. Chem.*, 1909, **65**, 641; J., 1919, **115**, 1269). The presence of such complex compounds or their resulting ions may be advanced as an alternative explanation of the violet coloration of cupric bromide in hydrobromic acid solutions. If this were the case it would be in agreement with an observation of Sabatier (*loc. cit.*), *viz.*, that the violet colour of a solution which has been just destroyed by dilution may be restored by gentle warming.



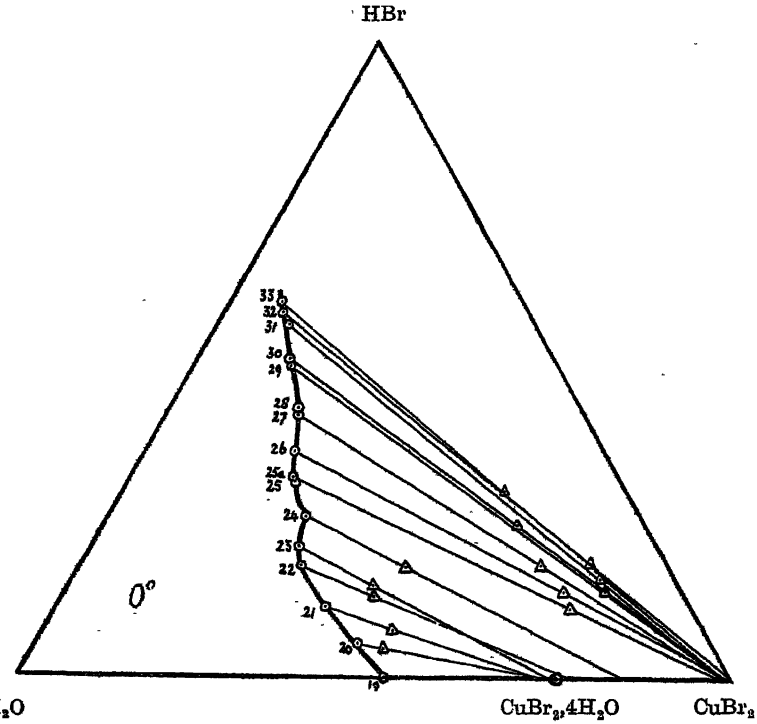
The actual causes of the colour changes in acid solutions of cupric bromide, however, cannot be decided simply by a consideration

of solid phases in equilibrium with them : a study of the solutions themselves would be necessary for a complete explanation.

The System $CuBr_2$–HBr–H_2O *at* 0°.

The system at 0° was investigated in a very similar way to that used at 25°, although some of the experimental details were slightly modified. The temperature of the thermostat was maintained constant by a mixture of water and crushed ice. The liquid phase

FIG. 4.



was extracted by means of the apparatus previously employed, but it was necessary to jacket the filter with ice-cold water. The solid phase was removed precisely as before, but it was found impracticable to carry out density determinations at 0°, partly by reason of the viscous nature of the solutions. For low concentrations of acid, it was deemed advisable to inoculate mixtures with a crystal of $CuBr_2,4H_2O$ after 2—3 hours in the solubility vessel, for otherwise, even after 7—8 hours there was considerable risk of supersaturation occurring, and of anhydrous bromide being left as the stable solid phase. Table IV and Fig. 5 summarise the results obtained for this system.

TABLE IV.

FIG. 5.

As with the curve at 25°, this system at 0° shows a sharp discontinuity, but in this case it is due to the solid phase changing from the tetrahydrate to the anhydrous salt. Mixture 24 is at the break and all points before that have the hydrated salt as their stable solid phase. It has already been determined for Mixture 19 that $CuBr_2 4H_2O$ is the stable phase at 0°. Addition of hydrobromic acid causes a lowering of the melting point of the hydrate,

i.e., it lowers the transition temperature. Hence, when sufficient acid has been added, the transition temperature falls to below 0°, and anhydrous cupric bromide becomes the only stable form.

Microscopic examination of the solid phase for Mixtures 19—22 showed green needles in a violet-brown or brown solution. Mixture 23 showed very few needles, for these decomposed with the heat of the room, their transition temperature probably being 3—4° in the prevailing concentration of acid: they could actually be seen decomposing and producing the characteristic black rhomboids of anhydrous bromide. Mixture 24 is peculiar, in that microscopic examination revealed only rhomboidal crystals, whilst the tie-line through its moist solid phase falls between $CuBr_2$ and $CuBr_2,4H_2O$, indicating that this point is at the junction of the two curves. Both solids are capable of existence here, but owing to temperature difficulties, the hydrate was not sufficiently stable to be seen. From Mixture 25 onwards, the only stable solid phase present was anhydrous cupric bromide; from its appearance under the microscope, it must have been the non-crystalline β-variety.

When the hydrobromic acid concentrations are increased, the cupric bromide solutions at 0° exhibit a sequence of colour changes from brown to violet which are similar to those observed at 25°. It is noteworthy that at high concentrations of acid (*i.e.*, in the region of the violet solutions) the same solid phase (β-$CuBr_2$) persists at both temperatures, whilst in the low acid concentrations (brown solutions) the solid phases at 25° and 0° are α-$CuBr_2$ and $CuBr_2,4H_2O$, respectively. No evidence of the formation of any ternary complex compound at 0° was obtained from the curve.

The general temperature relationships of the curves at 0° and 25° may be judged by an examination of Fig. 4. Over the greater part of the system, cupric bromide evidently possesses a positive temperature coefficient of solubility, and this is still more marked when $CuBr_2,4H_2O$ becomes the stable phase at 0°. In the neighbourhood of Mixture 24, however, on the curve at 0°, the curves cross, indicating that in this region the solubility of the salt in hydrobromic acid decreases with rise of temperature. There can be little doubt of the accuracy of the observation, since Mixtures 28, 27, 26, and 25 all tend towards the curve at 25°, but the region has not been investigated experimentally in greater detail.

Summary.

1. The solubility curve of the system $CuBr_2$–H_2O has been investigated over the range 0—50°, one of two solid phases, $CuBr_2,4H_2O$ and $CuBr_2$, being found according to the temperature of the solution.

2. The transition temperature has been determined as 18·00° ± 0·05°.

3. The solubility curve of the system $CuBr_2$–HBr–H_2O at 25° shows only a solid phase of anhydrous $CuBr_2$. There are two forms—α-$CuBr_2$, which has well-defined rhomboidal crystals, and β-$CuBr_2$, which is non-crystalline. The break between the two forms occurs at 26% of HBr.

4. A metastable portion of the system at 25° has been investigated and found to possess as its solid phase a complex compound of the probable formula $3CuBr_2,2HBr,6H_2O$, the stability of which is probably favoured by increase of temperature.

5. The system $CuBr_2$–HBr–H_2O has been investigated at 0°, and the solubility curve found to exhibit a break corresponding to the two stable phases $CuBr_2,4H_2O$ and β-$CuBr_2$.

6. The characteristic colour changes of cupric bromide in hydrogen bromide solutions have been discussed in the light of this investigation.

7. No evidence has been obtained of the existence of $CuBr_2,2H_2O$ in any of the systems studied.

[*Received, April 5th*, 1928.]

CCCXC.—*Studies in the Composition of Coal. The Rational Analysis of Coal.*

By WILFRED FRANCIS and RICHARD VERNON WHEELER.

A RATIONAL analysis of any coal can be given in terms of the proportions of free hydrocarbons, resinous compounds, organised plant entities, and ulmin compounds that it contains (see, *e.g.*, Cockram and Wheeler, J., 1927, 700), for these are the principal ingredients of the coal substance and they have characteristic properties. Such an analysis is not sufficient, however, to specify completely the quality of the coal, for the ulmin compounds, of which it is mainly composed, are not identical in character in all coals. We have, in fact, shown (J., 1925, **127**, 2236) that the properties of the ulmin compounds, which exist in all coals, from lignites to anthracites, are modified by progressive changes in molecular arrangement. When first formed by the decay of vegetable tissues, the ulmins are readily soluble in alkaline solutions, but the further the " coalification " of the material proceeds the less is its natural content of soluble ulmins and the less easily can such ulmins be " regenerated " by oxidation processes (see *Safety in Mines Research Board, Paper No.* 28, 1926).

Coals can differ from each other in respect of (1) the proportions and (2) the properties of their ingredients. There is sufficient evidence, which cannot be detailed here, that the chemical compositions of the free hydrocarbons, resinous compounds, and organised plant entities (*e.g.*, spore exines and cuticular tissues) do not vary much whether those bodies form part of a lignite, a bituminous coal, or a semi-anthracite. Certainly they do not vary sufficiently to account for the wide differences in properties of such coals. On the other hand, the composition of the ulmin compounds does vary widely, dependent upon the coals from which they are obtained, by reason of differences both in the external groupings of the large and complicated molecule and in its internal, or nuclear, structure.

A preliminary study of a series of coals suggested that a measure of the difference in character as between the ulmin compounds of two coals could be obtained by determining their reactivity; for example, as regards oxidation, from the proportion rendered soluble in alkalis after their subjection to limited oxidation under standard conditions. Such a measure, a "reactivity index" for the ulmins, should be sufficient, in addition to a rational analysis, to specify a coal so that its general properties would be discernible.

We have tested this suggestion by the examination of a series of coals from the same seam, the Pittsburgh seam of the United States of America. Some of the samples were obtained through the courtesy of Dr. David White, of the U.S. Geological Survey, who himself collected them; others were collected by one of us in person. The advantage of carrying out a study of this kind on coals from the same seam lies in the elimination of a possible complication due to wide differences in character of the vegetation from which the coals were formed.

The Pittsburgh seam extends conformably over wide areas in Pennsylvania, Ohio, West Virginia, and Maryland, and the coal varies in carbon content from 78% at its westernmost limit, where it is a sub-bituminous coal (Seyler's ortho-per-lignitous) to 90% in the Georges Creek region of Maryland, where it is a semi-anthracite (Seyler's sub-meta-bituminous). When the coal measures of the Allegheny formation were deposited, there existed over these areas a vast coastal plan, or an area of subsidence, upon which a series of almost continuous stretches of vegetation accumulated, each in turn to be gradually covered by detrital matter carried by the encroachment of water (see White, Bull. 38, *U.S. Bureau of Mines*, 1913). The Pittsburgh seam, which lies above the coals of the Allegheny formation, was formed under similar conditions. The variations in composition of the seam would thus appear to be due

mainly to changes in temperature and pressure caused by earth movements during the coalification process.

In addition to the Pittsburgh seam, coals were collected from the lignite fields of Montana, North Dakota, and Wyoming, from the bituminous fields near Price, in Utah, and from the Yampa Valley in Colorado, where local earth movements have transformed coals of comparatively recent formations into semi-anthracites. With the coals of the Pittsburgh seam, the earth movements responsible for their regional metamorphism were those resulting in the Allegheny mountains, the greatest upheavals being in the George's Creek district of Maryland (*e.g.*, the Ocean coal) and the least in Ohio (*e.g.*, the Bailey's Mills coal). In Montana and North Dakota, the earth movements which caused the change of rank of the coals were those which formed the Rocky Mountains. In places where the uplift of the mountains was not felt, as in North Dakota, the coal is a lignite. There is a general tendency for the rank of the coal to increase in a westerly direction (toward the Rocky Mountains), whilst it is highest in the neighbourhood of local upheavals.

The method of examination, in addition to the usual forms of analysis and the determination of the proportions of the principal ingredients, has been to measure the reactivity with oxygen of the ulmin constituents. This has been done both directly, from the amount of oxygen combining with them in a given time, and indirectly from the rate of production of alkali-soluble ulmins under standard treatment with an oxidising agent. It has been found that the order of reactivity of the ulmins as measured by each method is substantially the same. In Table I the rational analyses of the coals examined are recorded, together with their carbon contents. A "reactivity index" for the ulmins (obtained as described in the experimental part of this paper) is also included, and the coals are arranged (those of the Pittsburgh seam being grouped together) in two groups of decreasing reactivity.

In the rational analyses, the hydrocarbons and resins have been grouped together. These are oil-yielding constituents of high hydrogen content, and their presence in the coal in suitable amount affects (but is not wholly responsible for) its coking power. There is no general relationship between the quantity of hydrocarbons and resins extractable from a coal and its age or degree of coalification; nor is this to be expected, since the concentration, in the original coal-forming materials, of the substances that yielded them must have been to a certain extent accidental. Their quality also (*e.g.*, in the Pittsburgh seam) is but little altered by such changes of conditions as have had a marked effect on the ulmins;

They remain soluble in organic solvents, for example, except in that part of the seam that has been subjected to extreme tectonic disturbance, as in the Westmoreland and Somerset Counties of Pennsylvania and the George's Creek region of Maryland. In the samples obtained from these regions (the Vogele, Berkley, and Ocean Mines, Table I), the proportions of chloroform-soluble material have greatly diminished, and it can be assumed that the effects of the violent earth movements have been either to remove part of the hydrocarbons and resins (by distillation) or to render them insoluble.

Similarly, there is no connexion between the degree of coalification of the seam and the proportion of organised plant entities that it may contain. In the Pittsburgh seam the proportions of these bodies (which other researches have shown to be extremely resistant to decay and to the processes of coalification) vary at haphazard between 3 and 16%, dependent no doubt, as with the

resins, on their original, accidental, concentration in the coal-forming materials. The spore exines and cuticular tissues, which form the bulk of the morphologically organised plant entities, are of high hydrogen content and are oil-yielding constituents of the coal, the oils consisting mainly of paraffins and unsaturated hydrocarbons.

Regarding these non-ulmic organic constituents as impurities, it is desired to trace a relationship between the "reactivities" of the ulmin constituents and the chemical compositions of the coals as determined by ultimate analysis. It will be understood that, since the proportions of the non-ulmic constituents, of higher hydrogen content than the bulk of the coal, vary between rather wide limits (4·6—23·2% in the Pittsburgh seam), any such relationship can only be partial. The percentage of carbon, being high throughout the series of coals, should be least affected by the presence of varying quantities of materials of high hydrogen content. Table I shows that there is, in fact, a general relationship between the carbon content of the coal as a whole and the "reactivity" of the ulmins it contains, a relationship which is remarkably close when, in addition to the fact that the ultimate analysis shows no more than the mean carbon content of all the organic constituents of the coal, it is remembered that the accuracy of coal analyses, calculated, as is usual, on an ash-free, dry basis, suffers from the fact that the inorganic impurities differ in composition and amount from the ash they yield on incineration. For these reasons we consider the "reactivity index" of the ulmins to be a better measure of the degree of coalification than the carbon content of the coal as a whole can be, though the latter may often be a sufficiently close measure. For example, if care be taken to choose only the vitrain portion of a seam, the fact that this portion can readily be freed from all but a small percentage of mineral matter and is essentially free from spore exines and cuticles, causes the analysis to be nearly representative of the ulmin constituents alone. Thus, in Table II a comparison is made between the carbon contents of four coals and those of the vitrains separated from them. It will be seen that the "reactivity index" of the ulmins corresponds with the carbon content of the vitrain from the coal rather than with that of the coal as a whole.

What we have termed the "degree of coalification" of a coal is sometimes (following David White, *e.g.*, *U.S. Bureau of Mines*, Bull. No. 38, 1913) termed its "rank," a coal of lowest rank being one in which the processes of coalification (in whatever way induced, *i.e.*, whether by time, temperature, or pressure) have [illegible] result, and a coal of highest rank one in which such pro[illegible]

been the most effective. We have shown elsewhere (*loc. cit.*) that the external groupings of the ulmin molecules are modified with increasing rank of the coal. The present work affords additional evidence of this. From the results in Table III, which records the amounts of oxygen that combined with the coals at 150° (one method of determining the reactivity of the ulmins), it will be seen that the ratio between the oxygen that remained combined with the coal and the total consumed increases as the rank of the coal increases. In order that a given quantity of oxygen shall combine with an ulmin of low rank (forming acidic groupings), a greater total quantity must be consumed than with a high-rank ulmin, presumably because the nuclear groupings of the ulmin molecule of low rank are of smaller mass in comparison with that of the external groupings. These external groupings are the first points of attack by the oxygen (yielding water and oxides of carbon), and they confer high reactivity on the low-rank ulmins.

As the rank of the ulmins increases, the amount of oxygen that must combine with them, forming acidic groupings which confer on them solubility in alkaline solutions, also increases, whilst the ratio C : O in the soluble ulmins produced becomes greater (see Table III). This suggests that the nuclear structure of the ulmin molecules increases in magnitude with their rank, and that polymerisation or condensation takes place during the coalification process.

An important inference to be drawn from the examination of the Pittsburgh seam is that all coal ulmins which have the same "reactivity index" are alike in constitution and properties. Exceptions are apparent amongst coals of younger formations, explicable by reason of the widely distant geological periods during which the coal-forming materials accumulated, but there seems no reason why coals from the upper (and, perhaps, the middle) carboniferous period should differ materially in character from those of the Pittsburgh seam. For any such coal, a determination of the "reactivity index" of the ulmins, together with an estimation of the principal ingredients, should give more valuable information as to its properties than other forms of analysis. We are accumulating such data with regard to a number of British coals, using the methods now to be described.

Experimental.

For convenience, the coals are identified by the name of the mine at which the seam is worked. The positions of the mines are recorded in Table VI. The Pittsburgh seam varied in thickness from 4 to 10 ft., the others from 6 to 80 ft. With few exceptions (recorded in Table I), the samples, of about 10 lb. weight, were taken from the middle of the seam at a newly-exposed face. The blocks of coal were immediately wrapped in sheets of lead foil to prevent exposure to the air. In the laboratory, the coarsely ground samples were dried in a vacuum oven and extracted with pyridine in large Soxhlet apparatus in an atmosphere of nitrogen, and the γ_1- and γ_2-fractions separated by treatment with chloroform. The α- and β-compounds were then dried in a vacuum at 105°, ground, and sieved. All the oxidation experiments were made on samples so treated.

Rate of Oxidation.—To determine the rates of oxidation of the samples, 10 g. of each, sieved so as to pass a 100- and remain on a 200-mesh sieve (Tyler U.S. standard), were placed in glass tubes in a constant-temperature oven at 150°, and pure dry air was drawn through them for several weeks. The time taken for complete conversion of the coal ulmins into alkali-soluble compounds varied with the character of the coals, being as long as 40 weeks for those of highest carbon content. The quantities of water and oxides of carbon formed during the reaction were measured, as well as the changes in weights of the coals. The amounts of oxygen that remained combined with the residues, and the total oxygen consumed, could thus be estimated. The results for the first two weeks are recorded in Table III, the amounts of oxygen being expressed in c.c. per g. of ulmins free from unoxidisable plant entities and mineral matter.

So far as the coals of the Pittsburgh seam are concerned, their carbon contents follow closely the rates of oxidation of the ulmins, but amongst the other coals there are notable exceptions. For example, the ulmins of Colstrip coal react with less oxygen in a given time than do those from Wadge coal, though the carbon content of the former coal is the lower by 4%. There are possibilities of experimental error with such low-rank coals, both in the analyses, because of their high moisture contents, and in the measurements of rates of oxidation, because their avidity for oxygen might cause them to absorb appreciable quantities during their preliminary treatment. From superficial examination of these coals, however, one would judge the Colstrip to be of lower rank than the Wadge, the former having the dark brown, streaky appearance characteristic of sub-bituminous coals, and the latter being a brilliant black

Rate of Formation of Soluble Ulmins.—(a) *By atmospheric oxidation.* Samples were exposed in thin layers in an air-oven at 150° for several weeks. At the end of each week 1 g. of each was withdrawn and extracted during ½-hour with 150 c.c. of a boiling 1% potassium hydroxide solution. The solutions were filtered while hot, and the ulmins precipitated by hydrochloric acid, filtered through tared papers, washed, dried, and weighed.

The results are recorded in Table IV. In order to compare the reactivities of the coals, it is convenient to calculate the times taken for 50% production of soluble ulmins, figures readily obtainable from the data recorded with an accuracy within 1%. The coals are arranged on this basis in Table IV in order of decreasing activity. The order is substantially the same as that given by their rates of oxidation (Table III), and it will be noticed that those coals, of the younger formations (Colstrip, Owl Creek, and

Gantar), which were there placed low in order of reactivity (for their carbon contents) are again so placed.

One marked discrepancy between Tables III and IV is caused by the Knife River coal, which was one of the youngest studied. In appearance it resembled dark brown wood, the seam containing complete tree trunks. When mined, its content of soluble ulmins was 24%, but on drying at 104° this was reduced to 4% (despite the fact that about 35% of moisture was driven off). Even this moderate temperature, therefore, caused either dehydration or condensation of the ulmin molecules, an effect which heating in air at 150° would no doubt intensify, despite the fact that soluble ulmins were simultaneously formed by oxidation. With such coals the rate of formation of soluble ulmins during atmospheric oxidation cannot be used as a measure of their rank.

(b) *By chemical oxidants.* After a number of chemical oxidising agents had been tried, the most suitable was considered to be a mixture of hydrochloric acid and potassium chlorate (Hoffmeister's reagent). With this reagent a measure of the reactivity of the ulmins can be obtained fairly rapidly. The coals, freed from hydrocarbons and resins as previously described, were ground so as just to pass through a 150-mesh (Tyler U.S. standard) sieve, care being taken to avoid the production of fine dust. Several 0·5-g. samples of each of the treated coals were heated with 50 c.c. of *N*-hydrochloric acid and different weighed amounts of potassium chlorate in stoppered pressure bottles (370 c.c. capacity) in a bath of boiling water, during 6 hours. The bottles were allowed to cool over-night before being opened, and their contents were then filtered and the proportions of insoluble material determined. In recent work, this method has been modified in minor details.

A convenient measure of the reactivity of the coal ulmins, as determined by chemical oxidation, is given by the calculated percentage production of soluble products caused by 0·5 g. of potassium chlorate, such as is recorded in Table I as the " reactivity index." Such determinations may not be as accurate as those given by atmospheric oxidation, but they are more readily obtained, and for that reason we have chosen them for use in our table of " rational analyses." They are sufficiently accurate for practical purposes. This method of measuring the reactivity of the coal ulmins (see Table V) arranges the coals in nearly the same order as do the methods employing atmospheric oxidation, the younger coals, Colstrip, Owl Creek, and Gantar, again proving exceptions to the general relationship between reactivity and carbon content.

Determination of Hydrocarbons and Resins.—For some of the determinations, the usual method of separating the γ_1- and γ_2-compounds (see Cockram and Wheeler, *loc. cit.*) was simplified. The coals were extracted with pyridine in Soxhlet apparatus, in an atmosphere of nitrogen, during 16 hours. The pyridine solution was concentrated to small bulk, excess of chloroform added, and the pyridine neutralised with dilute hydrochloric acid, thus causing precipitation of the insoluble β-compounds and the dispersed γ_3- and γ_4-compounds. The γ_1- and γ_2-compounds, in solution, were estimated by evaporating off the chloroform and weighing.

Determination of Organised Plant Entities.—When the production of soluble ulmins is effected by atmospheric oxidation of the coals (freed from hydrocarbons and resins) at 150°, the determination of the proportion of organised plant entities is straightforward, for they, together with any mineral matter, constitute the residue remaining insoluble in alkaline solutions when the oxidation has

been carried to completion. This takes several weeks, however, and some more convenient method of estimation is essential. As the result of extensive tests in comparison with the results obtained by atmospheric oxidation, the following procedure, which gives reasonably accurate estimations, was adopted.

A sample (0·5 g.) of the coal (freed from hydrocarbons and resins) was boiled during 7 hours under a reflux condenser with one or other of the solutions specified in the accompanying table, according to its carbon content.

Carbon content of coal (% on ash-free, dry basis).	Oxidising solution. Nitric acid, c.c.	Water, c.c.	$KClO_3$, g.

CCCXCI.—*The Addition of Halogens to Unsaturated Acids and Esters. Part II. The Addition of "Bromine Chloride" to Phenylpropiolic Acid.*

By NORMAN WILLIAM HANSON and THOMAS CAMPBELL JAMES.

IT has been shown in Part I (this vol., p. 1955) that an equimolecular mixture of bromine and chlorine, dissolved in carbon tetrachloride ("bromine chloride" solution), reacts additively with cinnamic acid to form the two externally compensated stereoisomerides corresponding to the formula $C_6H_5\cdot CHCl\cdot CHBr\cdot CO_2H$.

Similar experiments with phenylpropiolic acid in the place of cinnamic acid have now given a mixture from which, by fractional crystallisation from light petroleum, two, and only two *acids* have been isolated. These are the geometrical isomerides which theory demands from the structural formula $C_6H_5\cdot CCl{:}CBr\cdot CO_2H$.

By exposure of a chloroform solution of the higher-melting acid (129°), mixed with a little bromine, to direct sunlight, this was almost entirely converted into its lower-melting isomeride (112°). The latter acid was unaffected by such treatment.

This transformation is parallel to that of the other [illegible]

cinnamic acids, since, under similar conditions, the higher-melting (m. p. 139°) αβ-dibromocinnamic acid is partly transformed into its lower-melting (m. p. 100°) isomeride (Roser and Haselhoff, *Annalen*, 1888, **247**, 140), and the lower-melting (m. p. 101°) αβ-dichlorocinnamic acid undergoes isomerisation into the higher-melting (m. p. 121°) acid (Stoermer and Heymann, *Ber.*, 1913, **46**, 1349). The stable transformation products in both of these cases possessed the *cis*-configuration, as will be shown.

The interconvertibility of the β-chloro-α-bromocinnamic acids is indicative of their geometrically, and not structurally isomeric relationship; thus the addition of " bromine chloride " corresponds to that of bromine to phenylpropiolic acid in non-hydroxylic solvents, since in this case also a mixture of the two geometrically isomeric αβ-dibromocinnamic acids is formed (Roser and Haselhoff, *loc. cit.*).

The corresponding addition of chlorine, however, gives rise to only one product, namely, *cis*-αβ-dichlorocinnamic acid (m. p. 121°) (Nissen, *Ber.*, 1892, **25**, 2665), but this apparent anomaly can probably be explained by the extremely labile nature of the lower-melting (100°) *trans*-isomeride (Stoermer and Heymann, *loc. cit.*).

The positions occupied by the respective halogen atoms in the chlorobromocinnamic acids have been determined by a study of the chlorobromoindone which is produced when the lower-melting (112°) isomeride is treated with cold concentrated sulphuric acid; this reaction, moreover, establishes the *cis*-configuration of this acid. The higher-melting acid is therefore the *trans*-isomeride, and this conclusion is borne out by the fact that it is not affected by treatment with sulphuric acid.

Indeed, it has been found most convenient to prepare the chlorobromoindone directly from the product of the interaction of phenylpropiolic acid and " bromine chloride," since the indone was readily separable from the residual *trans*-acid by solution in hot light petroleum.

Although this indone has the same melting point (105°) as that of the compound shown by Roser and Haselhoff (*Annalen*, 1888, **247**, 148) to be 2-chloro-3-bromo-1-ketoindene, yet an examination of its reactions has led to the conclusion that it is isomeric with the latter, and possesses the structure designated by *3-chloro-2-bromo-1-ketoindene*. The evidence adduced for such a structure is based on the fact, definitely established by Schlossberg (*Ber.*, 1900, **33**, 2425), that the halogen atom which occupies the α-position to the phenylene group (*i.e.*, the 3-position) is the more readily replaceable by univalent atoms or radicals.

The chlorobromoindone obtained from *cis*-chlorobromocinnamic

acid condensed readily with aniline, to form an anilido-derivative identical with that obtained by Roser and Haselhoff (*loc. cit.*) from 2 : 3-dibromoindone, which was therefore 2-bromo-3-anilidoindone.

The fact that as a result of this condensation hydrogen chloride is eliminated (as a quantitative experiment proved) establishes the structure of the substance as 3-chloro-2-bromoindone. Additional evidence favouring such a structure is afforded by the fact that the analogous piperidyl derivative was identical with that prepared by Roser and Haselhoff from 2 : 3-dibromoindone and piperidine.

Furthermore, an authentic specimen of 2-chloro-3-bromoindone, prepared by boiling 2 : 3-dichloroindone with alcoholic potassium bromide (Roser and Haselhoff) proved to be non-identical with the new chlorobromoindone, as was evinced by a mixed melting point, and by the non-identity of their *oximes*.

Consequently, the new indone must be formed by the elimination of water from *cis*-β-chloro-α-bromo-β-phenylacrylic acid, m. p. 112°, and since this is directly obtainable from its isomeride, m. p. 129°, the latter must possess the *trans*-configuration. The following table summarises the physical properties of these new chlorobromocinnamic acids and the already known αβ-dihalogenocinnamic acids :

Cinnamic acid.		M. p.	Crystalline form.	Solubility.	Stability.
β-Chloro-α-bromo-	*cis*	112°	Needles	More sol.	Stable
	trans	129	Plates	Less ,,	Labile
αβ-Dibromo-	*cis*	100	Needles	More ,,	Stable
	trans	139	Plates	Less ,,	Labile
αβ-Dichloro-	*cis*	121	Plates	Less ,,	Stable
	trans	100	Rhombic tablets	More ,,	Labile

The new chlorobromocinnamic acids are seen to possess physical properties analogous in every respect with those of their dibromo-congeners.

The positions taken up by the constituent atoms of the " bromine chloride " molecule when this unites with phenylpropiolic acid—the more negative atom uniting with the β-carbon atom—are the same as in the case where cinnamic is substituted for phenylpropiolic acid.

By a series of experiments conducted as described in Part I, " bromine chloride " has been found to react with phenylpropiolic acid at a much more rapid rate than either bromine or chlorine alone, the reaction being of the bimolecular type, without an inhibition period. Thus in yet another way is the reaction parallel to that for cinnamic acid and " bromine chloride."

The action of bromine and chlorine dissolved in carbon [illegible] chloride on the *cis*-isomerides of the three pairs of αβ-dihalogeno-

cinnamic acids above described (the *trans*-isomerides were not employed owing to their ready transformation into the *cis*-acids) is interesting.

The nature and extent of these reactions were determined by a series of experiments conducted as already described by Williams and James (this vol., p. 344). The mixed solutions of acid and halogen were sealed up in colourless glass bulbs and exposed to dull light, the residual halogen after definite time-intervals being determined by breaking the bulbs under potassium iodide and titrating the liberated iodine with standard thiosulphate.

The results obtained with bromine showed that in all three cases the amount of this halogen which disappeared was extremely small even after several weeks, and may even then have been due to substitution in the phenyl radical, so that no bromine addition products could be prepared.

αβ-Dichlorocinnamic acid formed an addition product with chlorine, *viz.*, *ααββ-tetrachloro-β-phenylpropionic acid*, m. p. 130°. This is the one product expected on theoretical grounds; it contains *no* asymmetric carbon atoms and is therefore not potentially optically active.

The results for αβ-dibromocinnamic acid and chlorine indicated that some replacement of the bromine in the acid by chlorine occurred, but no recognisable product could be isolated and there was no further reaction when the concentration of the total halogen was approximately half its initial value. This attainment of an approximate "equilibrium" may be ascribed either to the formation of an actual equilibrium between original acid, replaced acid, chlorine and bromine, or to the total disappearance of the chlorine by its substitutive and additive reactions, in which case the residual halogen would be the bromine liberated by replacement, which would be practically inert towards these acids.

A similar partial replacement of bromine by chlorine, and attainment of an approximate "equilibrium," occurred in the reaction between β-chloro-α-bromocinnamic acid and chlorine, but in this case about five-sixths of the halogen had disappeared at that stage. The main product of this reaction was the dichloride of the chlorobromo-acid, *viz.*, *αββ-trichloro-α-bromo-β-phenylpropionic acid*, m. p. 127°, but a small quantity of ααββ-tetrachloro-β-phenylpropionic acid was also formed.

The former of these products is the only addition compound expected on theoretical grounds: it contains only one asymmetric carbon atom, and may therefore be resolvable.

Corresponding experiments with "bromine chloride" in place of the pure halogens indicated that it did not react as a molecule of

such in these cases, the chlorine portion only appearing to be reactive.

The properties of the dichloro- and chlorobromo-cinnamic acids of forming addition products with chlorine but not with bromine, and of the replacement of part of the bromine by chlorine in the case of the latter acid, are not unique. For instance, tetraphenylethylene forms no addition product with bromine (Behr, *Ber.*, 1870, **3**, 753) but yields with chlorine a dichloride (Norris, Thomas, and Brown, *Ber.*, 1910, **43**, 2940). Further it has recently been shown by Meisenheimer (*Annalen*, 1927, **456**, 142) that triphenylbromoethylene, although it does not unite with bromine, reacts with excess of chlorine with replacement of the bromine atom and formation of a dichloride of the resulting product, triphenyltrichloroethane.

Experimental.

When a suspension of phenylpropiolic acid in carbon tetrachloride was treated at 0° and in the dark with " bromine chloride " (1 mol.) dissolved in the same solvent, the acid gradually went into solution. After a few hours the solvent was removed by evaporation in a vacuum, and the resulting crystalline mass dissolved in hot chloroform. On adding light petroleum to this solution until cloudy and allowing it to cool, colourless crystalline plates and clusters of straw-coloured needles were deposited. The mother-liquid was decanted, and the mixture of crystals warmed with light petroleum; the needles alone went into solution. The plates, after being washed with more hot light petroleum, melted at 129° (Found: Br, 30·0; Cl, 13·8. $C_9H_6O_2ClBr$ requires Br, 30·6; Cl, 13·6%). The hot petroleum from the first extraction deposited, on cooling, clusters of long, straw-coloured needles, m. p. 112° (Found: Br, 30·0; Cl, 13·7%). The proportion of the higher- to the lower-melting *chlorobromocinnamic acid* was approximately 1 : 4. A successful separation of the two acids could not be accomplished by any of the other methods commonly employed in similar cases.

When the mixed chlorobromocinnamic acids obtained by addition of " bromine chloride " to phenylpropiolic acid were rubbed with excess of cold concentrated sulphuric acid, a dark brown solution was formed, which, when poured into a large volume of cold water, yielded a quantity of golden-yellow flocks. Hot light petroleum dissolved the coloured constituent of the dried product, leaving undissolved a small proportion (about one-fifth of the original mixture) of small colourless plates of the higher-melting chlorobromocinnamic acid (m. p. 129°). The petroleum extract deposited *3-chloro-2-bromo-1-ketoindene* in clusters of golden-yellow

m. p. 105° (Found: Br, 32·7; Cl, 10·9. C_9H_4OClBr requires Br, 32·9; Cl, 10·8%).

The indone, when warmed with excess of aniline in alcoholic solution, yielded bright scarlet needles of 2-bromo-3-anilidoindone, m. p. 170°, as described by Roser and Haselhoff (*loc. cit.*). That hydrogen chloride was eliminated by this condensation is proved by the following results:

0·204 G. of the indone was treated with alcoholic aniline, and the anilido-compound removed. The filtrate gave 0·1220 g. of silver halide, which was not reduced in weight when warmed in a stream of chlorine, and was hence silver chloride (Calc. for 100% evolution of hydrogen chloride: AgCl, 0·1200 g.).

The chlorobromoindone, when treated with piperidine as for aniline, gave bright red tables of 3-piperidyl-2-bromo-1-ketoindene, m. p. 117° (decomp.) (Roser and Haselhoff, *loc. cit.*).

By boiling the indone in alcoholic solution with hydroxylamine hydrochloride, pouring the mixture into water, and crystallising the precipitated yellow powder from alcohol, *3-chloro-2-bromo-1-keto-indene oxime* was obtained as silky yellow needles, m. p. 194° (decomp.) (Found: Br, 30·1; Cl, 14·1. $C_9H_5ONClBr$ requires Br, 30·9; Cl, 13·7%).

2-Chloro-3-bromo-1-ketoindene, prepared as described by Roser and Haselhoff, melted at 105°; a mixture of this and the above-described 3-chloro-2-bromo-1-ketoindene melted indefinitely at 65—100°. The *oxime* of the former compound, prepared as described for the latter, melted at 184° (decomp.) (Found: Br, 30·3; Cl, 13·6%).

The results of kinetic experiments with phenylpropiolic acid and "bromine chloride," bromine, and chlorine, respectively, are summarised in the table. The corresponding figures for cinnamic acid and these reagents are given for comparison purposes. Experiments were conducted at 0°, in the dark, and in carbon tetrachloride solution. The bimolecular velocity coefficient $k = 1/t \,.\, x/a(a - x)$, is calculated on the basis of t in hours and concentrations (a and x) in g.-mols. per litre.

	Bromine	0·173—0·041	0·146
	Chlorine	0·265—0·153	0·209

Although phenylpropiolic acid is more unsaturated than cinnamic acid, the halogens react with the former at a slower rate than with the latter. The hydrogen atoms in the cinnamic acid side chain probably play an important part in this connexion.

cis-αβ-Dichlorocinnamic acid, treated with chlorine (1 mol.) in carbon tetrachloride solution, and exposed to diffused light for 5 weeks, yielded a product which crystallised from carbon tetrachloride in colourless prisms, m. p. 130° (Found: Cl, 48·8. $C_9H_6O_2Cl_4$ requires Cl, 49·2%). The product is therefore *ααββ-tetrachloro-β-phenylpropionic acid.*

cis-β-Chloro-α-bromocinnamic acid reacted with chlorine, with partial replacement of bromine by chlorine, and formation of the corresponding addition product, ααββ-tetrachloro-β-phenylpropionic acid in small amount, the main product being the dichloride of the original chlorobromo-acid, *viz.*, *ααββ-trichloro-α-bromo-β-phenylpropionic acid*, m. p. 127° (Found: Br, 24·0; Cl, 31·7. $C_9H_6O_2Cl_3Br$ requires Br, 24·0; Cl, 32·0%). The products were separated by fractional crystallisation from carbon tetrachloride.

One of us (N. W. H.) desires to record his indebtedness to the Department of Scientific and Industrial Research for a maintenance grant.

CCCXCII.—*Studies in Complex Salts. Part I. The Preparation and Properties of Some Selenitopentamminecobalt Salts.*

By HARRY LISTER RILEY.

ALTHOUGH carbonatopentammine compounds have been described (Werner and Goslings, *Ber.*, 1903, **36**, 2378), the carbonate ion appears to have a greater tendency to occupy two positions in the complex, as judged from a consideration of methods of preparation and relative yields. Complex salts have been described containing sulphato-, sulphito- (Riesenfeld, *Z. anorg. Chem.*, 1924, **132**, 99), chromato- (Briggs, J., 1919, **115**, 67), and selenato- (Meyer, *Z. anorg. Chem.*, 1921, **118**, 1) groups, and in the case of the first three groups both pentammine and tetrammine compounds have been prepared. Riesenfeld pointed out (*loc. cit.*) that the sulphito-group almost invariably occupies only one position in the co-ordination complex, and advanced experimental evidence in favour of a tetrahedral structure for those compounds where this group has been represented as occupying two positions in the complex. The tetrammine sulphato- and chromato-compounds were prepared from the corresponding carbonato- or diaquo-tetrammine compound,

no record of these compounds having been prepared in a manner similar to that employed in the case of the carbonatotetrammine compound (Jörgensen, *Z. anorg. Chem.*, 1892, **2**, 282).

The reason for this difference in the properties of these ions becomes apparent on the basis of modern electronic theory. The tendency of a molecule or ion to enter the co-ordinated complex depends on its possession of a "lone pair" of electrons and upon the distribution of the charges within the molecule or ion. A comparison of the structure of the various ions under consideration at once suggests an explanation of their differences in behaviour.

Carbonato-. Co-ordinate valency usually 2.

Sulphato-. Sulphito-. Co-ordinate valencies usually 1.

The effect of the positive charges on the sulphur atom is to cause the electrons round the oxygen atoms to be held much more firmly and to reduce their tendency to form a co-ordinate link. When one link is formed, the tendency to form a second will be less still. In the carbonato-ion the carbon atom is electrically neutral, so the negative oxygen atoms will possess a greater tendency to form a co-ordinate link than if the carbon atom were positively charged. The formation of one co-ordinate link will reduce the tendency to form a second.

In order to test the above ideas, it was decided to attempt the preparation of some selenito-complex salts (which have not previously been described) by a method similar to that employed in the preparation of carbonato-tetrammine and -pentammine compounds, examining the product of oxidation for both pentammine and tetrammine compounds.

EXPERIMENTAL.

Preparation of Selenitopentamminecobaltic Chloride.—To 18 g. of freshly precipitated cobaltous hydroxide were added 22 g. of selenium dioxide (prepared from metallic selenium by oxidation with nitric acid and subsequent sublimation), and 11 g. of ammonium chloride, followed by a little water and a large excess of ammonia (*d* 0·880). The whole was well stirred until everything soluble had dissolved. A rapid current of air was passed through the filtered solution until it no longer contained free ammonia (about 12 hrs.), its colour changing from brownish-red to a deep ruby-red. The solution (about 400 c.c.) was evaporated to 100 c.c. in a vacuum over concentrated sulphuric acid. As no crystallisation had occurred

at this stage, 250 c.c. of alcohol were slowly added with continuous stirring. A deep red, oily liquid separated which slowly solidified to a crystalline mass. The clear supernatant liquid was decanted, and on being tested with barium chloride showed the presence of selenite ions. The solid mass was dissolved in 100 c.c. of water and again precipitated with 250 c.c. of alcohol. The supernatant liquid, which was again decanted, gave no precipitate with barium chloride. The solid was dissolved in 80 c.c. of water, 150 c.c. of alcohol were added, and the mixture was kept for 2 days, a few c.c. of alcohol being added from time to time. It was thus possible to grow quite large crystals, some of them about 2 cm. long, which on examination under the microscope, proved to be not single crystals but aggregates of small crystals belonging to either the rhombic or the tetragonal system. The large crystals were deep brownish-red, whereas the small, rapidly precipitated crystals were much lighter in colour. A yield of over 80% of *selenitopentammine-cobaltic chloride* (of above 98% purity) was obtained (Found: Co, 19·36; SeO_3, 40·81; NH_3, 27·34; Cl, 11·72; Co : SeO_3 : NH_3 : Cl = 1·02 : 1·00 : 5·01 : 1·03. $[Co(SeO_3)(NH_3)_5]Cl$ requires Co, 19·22; SeO_3, 41·49; NH_3, 27·72; Cl, 11·57%). Some of the crystals, after being air-dried, were placed in a vacuum desiccator over sulphuric acid for 2 days. No loss in weight occurred.

Analysis.—The following method was adopted for the analysis of the crystals. *Selenium.* About 0·3 g. of the substance was dissolved in 100 c.c. of water, 2—3 c.c. of concentrated hydrochloric acid were added, and then 30 c.c. of saturated sulphurous acid solution, and the whole was boiled for 5 hours, with the addition of more sulphurous acid from time to time. The precipitated selenium was washed, dried at 90—95°, and weighed.

Cobalt. The filtrate from the selenium was evaporated to dryness with the addition of a slight excess of sulphuric acid. The cobalt sulphate formed was heated at 400—450° and weighed. Ammonia and chlorine were estimated by the usual methods.

The reactions of the compound proved conclusively that it possessed the assigned constitution. Its solution in water, in which it is extremely soluble, gives no precipitate with barium chloride in the cold, showing the absence of selenite ions. On boiling, a precipitate containing barium, cobalt, and selenium is thrown down. Sulphur dioxide precipitates selenium from a hot solution containing hydrochloric acid, but the precipitation is complete only after prolonged boiling (see analysis, above). A concentrated solution of the salt containing a little sulphuric acid gives a precipitate with ferrous sulphate solution only after a few minutes' boiling. Hydrogen sulphide gives an immediate precipitate of sulphur and

Silver nitrate precipitates the chlorine completely from a cold solution. Sodium hydroxide only precipitates the cobalt on boiling, ammonia being evolved. When a solution of the compound is boiled with dilute hydrochloric acid (1 : 3), a ruby-red, crystalline substance is precipitated; this was shown to be chloropentammine-cobaltic chloride: $[Co(SeO_3)(NH_3)_5]Cl + 2HCl = [CoCl(NH_3)_5]Cl_2 + H_2SeO_3$. Molecular-weight determinations (cryoscopic in water) indicated that the compound is a binary electrolyte of the above formula, dissociating to the extent of 80% in 0·23*N*-solution and 97% in 0·1*N*-solution.

Another series of experiments was made in which various fractions, obtained by precipitating the original oxidised solution with alcohol, were analysed: in no case was the ratio $NH_3 : SeO_3$ less than 5 : 1. The high solubility of these selenito-compounds makes it impossible to be sure that no tetrammine compound is formed, but the above experiments prove that, if it is formed at all, it can only be present in very small amounts.

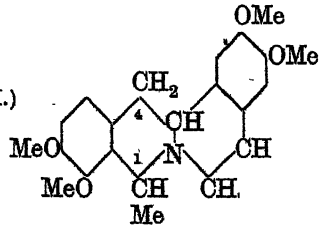
Selenitopentamminecobaltic Selenite.—An attempt to prepare this compound was made by the following method: To 18 g. of freshly precipitated cobaltous selenite were added 6 g. of selenium dioxide, a little water, and a large excess of ammonia (*d* 0·880). The resulting clear solution was oxidised by a rapid current of air until free from excess of ammonia (12 hrs.). The solution was evaporated in a vacuum over concentrated sulphuric acid. No crystallisation occurred, but a thick, oily syrup resulted. This was dissolved in a little water, and the filtered solution precipitated with alcohol, the process being carried out five times. The resulting syrup was evaporated in a vacuum over concentrated sulphuric acid for several days, and then solidified to a dark red, crystalline mass [Found: Co, 16·51; SeO_3, 52·75; NH_3, 23·28; H_2O (by diff.), 7·46. $[Co(SeO_3)(NH_3)_5]_2SeO_3,3H_2O$ requires Co, 16·29; SeO_3, 52·74; NH_3, 23·50; H_2O, 7·46%], which was extremely deliquescent, rapidly changing to a viscous liquid on exposure to the atmosphere. The aqueous solution rapidly became turbid. Barium chloride precipitated barium selenite along with some cobalt selenite from the cold solution. On removing this precipitate and reducing the acidified filtrate with hydroxylamine hydrochloride, selenium was precipitated, thus indicating the presence of both ionised and co-ordinated selenite groups. Water was shown to be present in the compound qualitatively; it was not removed by long exposure to sulphuric acid in a vacuum. The compound analysed was probably appreciably decomposed.

An attempt to estimate ionised and co-ordinated selenium separately led to inconclusive results. Hydrolysis always occurred

during attempts to dissolve the substance even in ice-cold water. The analysis showed, however, that the substance does contain the selenito-group in the complex and that the ratio $NH_3 : SeO_3$ is 5 : 1·5, which is in agreement with the proposed formula. The high solubility and rather unstable nature of the substance make it impossible to obtain it pure.

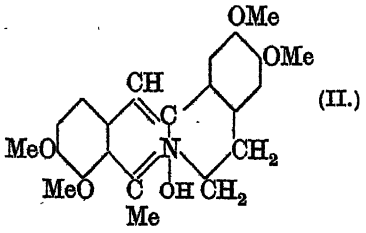
Summary.

Ions which possess an electrovalency of two show varying co-ordination valencies. The carbonate ion usually occupies two positions, but sometimes only one. Ions of the sulphate and sulphite types possess a greater tendency to occupy one position in the complex. An explanation of this behaviour is advanced, and evidence in agreement with this explanation is obtained from a study of the properties of two selenitopentamminecobaltic salts which were specially prepared for this purpose.



IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY,
SOUTH KENSINGTON. [*Received, July 17th*, 1928.]

CCCXCIII.—*Synthesis of Oxydehydrocorydaline.*



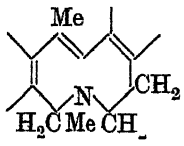
By JOSEPH BLAKE KOEPFLI and WILLIAM HENRY PERKIN, jun.

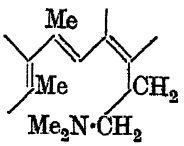
CORYDALINE, $C_{22}H_{27}O_4N$, the principal alkaloid occurring in *Corydalis cava* and *Corydalis tuberosa*, was first isolated by Wackenroder (*Berz. Jahr.*, 1826, **7**, 220); it melts at 133° and has $[\alpha]_D^{20°}$ + 300° (in chloroform). Our knowledge of the constitution of this alkaloid is very largely due to the researches of Dobbie and Lauder (J., 1902, **81**, 148), who, mainly as the result of the study of the substances obtained on oxidation and the comparison of these with the corresponding substances derived from berberine under like conditions, concluded that the constitution (I) must be assigned to corydaline.

(I.)

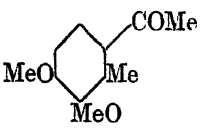
(II.)

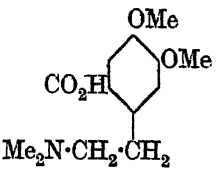
This formula represents corydaline as the methyl derivative of tetrahydropalmatine containing the methyl group in the position





This view of the constitution of the alkaloid held the

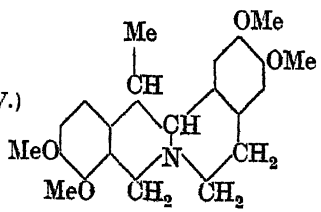


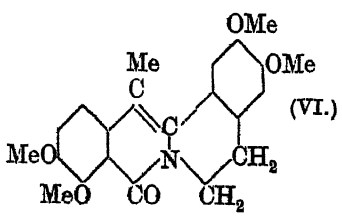


several years and was also adopted by Gadamer (*Arch. Pharm.*, 1910, **248**, 205) after the careful consideration of several alternative expressions. Perhaps the most characteristic property of corydaline is its conversion by mild oxidising agents with loss of four atoms of hydrogen into the yellow base dehydrocorydaline, $C_{22}H_{25}O_5N$, which closely resembles berberine in appearance and in several of its properties and was therefore assumed to be the methylpalmatine (II) containing the methyl group again in position 1. Confirmation of this view was thought to be disclosed by the fact that, for a long time, it was not found possible to convert dehydrocorydaline chloride into derivatives corresponding with oxyberberine and dihydroberberine, and the failure to undergo this characteristic reaction was assumed to be due to the presence of the methyl group in the position 1.

However, in 1922, Gadamer and von Bruchhausen (*Arch. Pharm.*, **259**, 249) succeeded in bringing about this change by treating dehydrocorydaline acetate with sodium hydroxide, and this important result was the first clear indication that the methyl group in corydaline could not be situated in position 1. Further evidence on this point was also furnished by Späth and Lang (*Ber.*, 1921, **54**, 3074), who converted palmatine iodide, by the action of magnesium methyl iodide and subsequent reduction, into two isomeric methyltetrahydropalmatines, neither of which was identical with *dl*-corydaline. Since, however, the researches of Freund and Beck (*Ber.*, 1904, **37**, 4674) have shown that, when the Grignard reagent reacts with salts of berberine, it is the hydrogen atom (1) which becomes replaced, and it may be assumed that the salts of palmatine will behave in a similar manner, the methyltetrahydropalmatines obtained by Späth and Lang should both contain the methyl group in position 1 and one of them should be identical with *dl*-corydaline (I), which, however, is not the case. More conclusive evidence in support of this view and indicating that position 4 must be assigned to the methyl group was subsequently brought forward by von Bruchhausen (*Arch. Pharm.*, 1923, **261**, 31).

This author achieved a partial synthesis of *d*-corydaline by methylating palmatine acetone with methyl iodide and reducing the methylated product with zinc and sulphuric acid. Since the researches of Freund and Speyer (*Annalen*, 1913, **397**, 1) and Freund and Fleischer (*ibid.*, 1915, **409**, 194) have shown that, when substances of the dihydroberberine type, to which palmatine acetone is supposed to belong, interact with methyl iodide, it is the hydrogen atom in position 4 which is reactive and becomes replaced by methyl, von Bruchhausen maintains that his synthesis is strong evidence that, in corydaline, the methyl group must occupy the position 4.

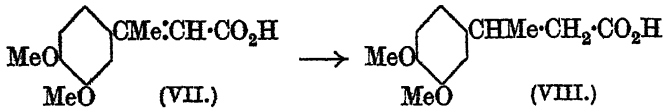




More recently still, von Bruchhausen and Stippler (*Arch. Pharm.*, 1927, **265**, 152) converted corydaline methochloride into the anhydro-base (III) [compare anhydromethyltetrahydropalmatine (A), J., 1927, 2262], reduced the methosulphate of this with sodium amalgam to (IV), and showed that this substance on oxidation with permanganate yields methylacetoveratrone and, with ozone, 4 : 5-dimethoxy-2-dimethylaminoethylbenzoic acid. Not only is this interesting series of decompositions (compare J., 1916, **109**, 821), which may be represented by the partial formulæ

(III.)  (IV.) 

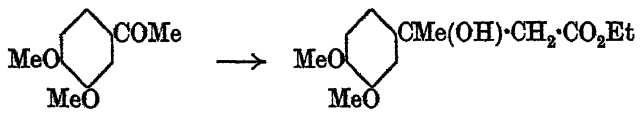
 and 



valuable general evidence of the constitution of corydaline, but, in particular, the formation of methylacetoveratrone may be taken as supporting the view that the methyl group in corydaline occupies the position 4.

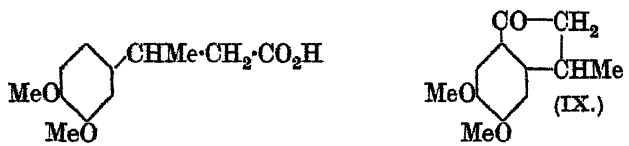
This brief sketch shows that the evidence which gradually accumulated had become strongly in favour of the view that the constitution of corydaline must be represented by (V) and not by the

(V.)   (VI.)



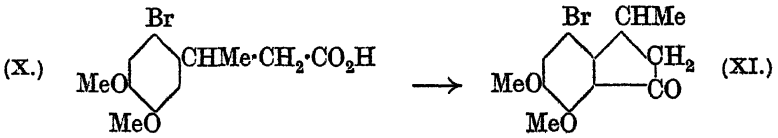
formula (I) of Dobbie and Lauder but, in order definitely to settle this matter, it seemed to us that it would be of interest to attempt to carry out a complete synthesis either of corydaline itself or of some highly characteristic derivative of the alkaloid. The derivative selected in the first place was oxydehydrocorydaline (VI), and the experience gained in the course of previous synthetical work in this group of alkaloids suggested that the best starting point for the synthesis would be β-veratrylbutyric acid (VIII). This we suggested

to obtain by reducing the corresponding β-*veratrylcrotonic acid* (VII). But the acid (VII) proved difficult to prepare : among the unsuccessful attempts to obtain it may be mentioned the condensation of

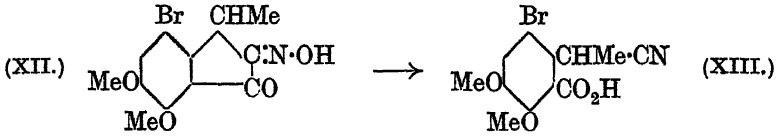


acetoveratrone with malonic acid and acetic anhydride (Massot, *Ber.*, 1894, **27**, 1225) or acetic anhydride and sulphuric acid (Meldrum, J., 1908, **93**, 598), and various processes involving the Claisen condensation.

Ultimately, acetoveratrone was found to interact readily with ethyl bromoacetate in the presence of zinc (Lindenbaum, *Ber.*, 1917, **50**, 1270) :

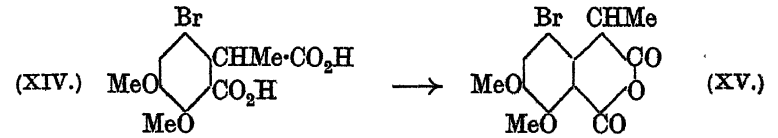


the crude ethyl β-veratryl-β-hydroxybutyrate, when distilled under reduced pressure, decomposed with the loss of water and formation of *ethyl* β-*veratrylcrotonate*. The free acid (VII), readily obtained from the ester by hydrolysis, was reduced by sodium amalgam to β-*veratrylbutyric acid* (VIII) and this, on treatment with sulphuric acid, yielded 5 : 6-*dimethoxy*-3-*methyl*-1-*hydrindone* (IX), a substance

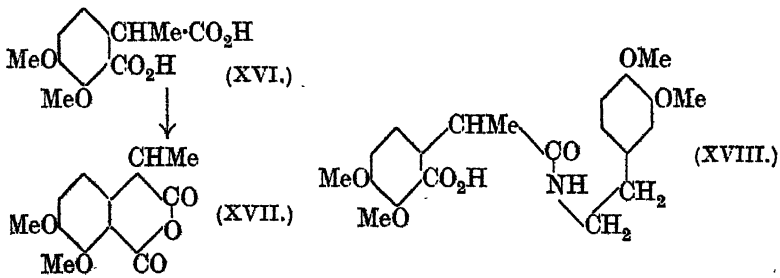


which was carefully characterised by conversion into the *oxime* and iso*nitroso*-derivative.

The formation of the hydrindone (IX) as the sole product of the dehydration is due to the well-known tendency to ring closure in the 6-position, para to one of the methoxy-groups. As it was necessary for the purpose of the synthesis of oxydehydrocorydaline that this should not occur but that the hydrindone formation should take place in the position 2, the 6-position was protected by the introduction of a bromine atom (Haworth, Perkin, and Stevens, J., 1926, 1764; Haworth, Koepfli, and Perkin, J., 1927, 548). 6-*Bromo*-β-*veratrylbutyric acid* (X), obtained by treating the acid (VIII) in glacial acetic acid solution with bromine, readily suffered

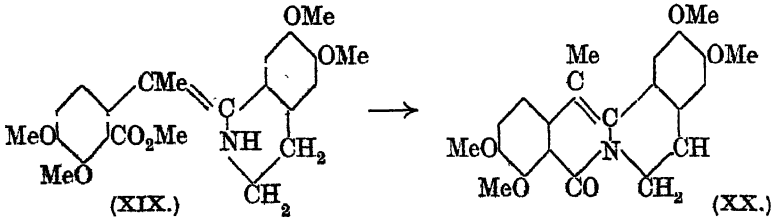


ring closure when warmed with sulphuric acid and yielded 4-*bromo*-6 : 7-*dimethoxy*-3-*methyl*-1-*hydrindone* (XI).



When the iso*nitroso*-derivative (XII) of this hydrindone, dissolved in sodium hydroxide, was treated with toluene-*p*-sulphonyl chloride, it underwent the Beckmann transformation and a good yield of 6-bromo-2-carboxy-3 : 4-dimethoxy-α-phenylpropionitrile (XIII) was obtained.

This was converted, on hydrolysis, into 6-bromo-3 : 4-dimethoxy-α-methylhomophthalic acid (XIV), a gum from which the crystalline *anhydride* (XV) was obtained by the action of acetyl chloride.



The anhydride was hydrolysed in alkaline solution and debrominated with sodium amalgam, and the crude 3 : 4-dimethoxy-α-methylhomophthalic acid (XVI) converted into the *anhydride* (XVII) by the action of acetyl chloride.

The anhydride (XVII) was now combined with β-veratrylethylamine (Haworth, Perkin, and Pink, J., 1925, **127**, 1709) by boiling the two substances together in benzene solution, the *N*-β-veratryl[illegible] 3 : 4-dimethoxy-α-methylhomophthalamic acid (XVIII) obtained was converted into the methyl ester, and this treated with phos-

phorus oxychloride in the expectation that methyl alcohol as well as water would be eliminated with the formation of oxydehydrocorydaline just as, for example, the methyl ester of *N*-β-veratrylethyl-3 : 4-dimethoxyhomophthalamic acid passes so easily under the same conditions directly into oxypalmatine (Haworth, Koepfli, and Perkin, J., 1927, 549).

However, in the present instance, the methyl ester lost only water on treatment with phosphorus oxychloride and yielded a substance, $C_{23}H_{27}O_6N$, which was clearly 6 : 7 : 3′ : 4′-*tetramethoxy*-9-*methyl*-2′-*carbomethoxy*-3 : 4-*dihydroprotopapaverine* (XIX),* because when heated at 150—170° it yielded oxydehydrocorydaline (XX) with elimination of methyl alcohol.

It has already been pointed out (p. 2990) that oxydehydrocorydaline was first prepared by Gadamer and von Bruchhausen from dehydrocorydaline acetate by the action of sodium hydroxide, and these investigators describe it as crystallising from acetic acid in pale yellow, four-sided tablets, m. p. 228—228·5°. The substance which we obtained synthetically, after repeated crystallisation from alcohol, was nearly colourless and melted at 235—236°. We are much indebted to Dr. von Bruchhausen for kindly sending us a specimen of the oxydehydrocorydaline obtained from dehydrocorydaline acetate. After two crystallisations from alcohol, this was still pale yellow but the m. p. had risen to 234—236°, and a mixture with the synthetical substance showed no depression in melting point. There can therefore be no doubt that the two specimens are identical and that the substance obtained synthetically is in fact oxydehydrocorydaline. This synthesis of the substance clearly demonstrates that the constitution of corydaline must be that represented by formula (V).

Preliminary experiments made with the object of converting oxydehydrocorydaline into *dl*-corydaline by electrolytic reduction seem to indicate that this process does not take place so readily as the conversion of oxyberberine into tetrahydroberberine (Perkin, J., 1918, **113**, 737). When larger amounts of material are available it will be possible to decide whether the change can be brought about

* For nomenclature, see Buck, Perkin, and Stevens (J., 1925, **127**, 1462).

in this way or whether some other process of reduction must be employed.

EXPERIMENTAL.

Acetoveratrone, $C_6H_3(OMe)_2 \cdot COMe$.—Veratrole (290 g.), prepared by the action of methyl sulphate on guaiacol (Perkin and Weizmann, J., 1906, **89**, 1649), was dissolved in carbon disulphide (750 c.c.) and mixed with acetyl chloride (197 g.). Aluminium chloride (290 g.) was added to the ice-cold mixture in small portions with constant shaking, and the reaction completed by warming at 50° for a short time. The magenta-coloured crystalline mass was separated from the carbon disulphide and decomposed with ice, the whole extracted with chloroform, and the chloroform solution washed with dilute sodium hydroxide solution and with water and dried over calcium chloride. After removal of the solvent on the steam-bath, the residue was distilled under reduced pressure, acetoveratrone being obtained as a colourless oil (297 g.), b. p. 160—162°/10 mm., which crystallised on standing.

Ethyl β-Veratrylcrotonate (formula as VII).—Acetoveratrone (45 g.) and ethyl bromoacetate (50 g.) in dry benzene (280 c.c.) were placed in a 1·5-litre flask together with zinc turnings (20 g.) and heat was applied until the reaction commenced. After this had subsided, the liquid was boiled under reflux for ¾ hour, cooled, decanted from undissolved zinc, and shaken with dilute sulphuric acid. The yellow benzene solution was dried over anhydrous sodium sulphate, the solvent removed on the steam-bath, and the residual light yellow oil, consisting of crude ethyl β-veratryl-β-hydroxybutyrate (p. 2992), distilled twice under diminished pressure; the resulting *ethyl β-veratrylcrotonate* (50 g.), b. p. 195—196°/10 mm., crystallised from ligroin in large colourless prisms, m. p. 51—52° (Found: C, 67·1; H, 7·1. $C_{14}H_{18}O_4$ requires C, 67·2; H, 7·2%).

In another experiment, ethyl β-veratryl-β-hydroxybutyrate (50 g.) was refluxed in dry benzene (200 c.c.) with phosphorus oxychloride (15 c.c.) for 30 minutes. The benzene solution, which turned dark red, was washed with water and dried over sodium sulphate, and the solvent removed on the steam-bath. The dark red oil, distilled under diminished pressure, gave ethyl β-veratrylcrotonate (30 g.), and a residue which could not be distilled without decomposition. This was hydrolysed with alcoholic potassium hydroxide and the solution was diluted with water, concentrated under diminished pressure on the steam-bath, and acidified; an amorphous mass then separated which, after solution in bicarbonate, extraction with ether and chloroform, and reprecipitation, could ultimately be obtained crystalline from [illegible] alcohol, separating in colourless prisms, m. p. 225—226° [illegible].

C, 64·8; H, 6·5; *M*, in camphor by Rast's method, 482. $C_{24}H_{28}O_8$ requires C, 64·8; H, 6·3%; *M*, 444). This *substance*, which does not appear to be reduced by sodium amalgam, is evidently produced from two molecules of veratrylhydroxybutyric acid by the elimination of two molecules of water ($2C_{12}H_{16}O_5 - 2H_2O = C_{24}H_{28}O_8$). The amount of available material was, however, so small that no further experiments were made with the substance.

β-*Veratrylcrotonic acid* (VII) was prepared by refluxing the ester (155 g.) with alcohol (500 c.c.), water (40 c.c.), and potassium hydroxide (42 g.) for 2 hours. The solution was diluted with twice its bulk of water, concentrated under diminished pressure on the steam-bath, and acidified with hydrochloric acid; the crude brown *acid* (120 g.) obtained crystallised from benzene in pointed prisms, m. p. 138—140° (Found: C, 64·7; H, 6·3. $C_{12}H_{14}O_4$ requires C, 64·8; H, 6·3%). It is sparingly soluble in water but readily soluble in the usual organic solvents with the exception of petroleum. The solution in concentrated sulphuric acid is yellow and exhibits a greenish fluorescence on standing.

The aqueous and the benzene mother-liquor (above) contain considerable quantities of a second acid which has not yet been carefully examined; it melts at 90—95° and is probably a stereoisomeride (compare Johnson and Kon, J., 1926, 2749).

β-*Veratrylbutyric Acid* (VIII).—β-Veratrylcrotonic acid (90 g.), dissolved in water (2·5 l.) and sodium hydroxide (17 g.), was treated with sodium amalgam (4 kg. of 4%) at 85—90° with mechanical stirring. After 12 hours, the cooled and filtered solution was nearly neutralised with hydrochloric acid, and a cold aqueous solution of permanganate (100 c.c. of 1%) added. After a few minutes, sulphur dioxide in excess was passed in and the white precipitate of the acid was collected, washed well, dried in a vacuum desiccator, and crystallised from benzene, separating in pointed prisms (Found: C, 64·2; H, 7·1. $C_{12}H_{16}O_4$ requires C, 64·3; H, 7·1%).

β-*Veratrylbutyric acid* melts at 84—85° and is very soluble in methyl alcohol but sparingly soluble in water or petroleum. It separates from dilute acetic acid in slender elongated prisms containing $1H_2O$: these melt at about 60—61° and lose water at 100°; the solid remaining melts at 84—85° (Found: loss at 100°, 8·3. $C_{12}H_{16}O_4,H_2O$ requires H_2O, 7·5%).

5 : 6-*Dimethoxy*-3-*methyl*-1-*hydrindone* (IX).—β-Veratrylbutyric acid (7 g.) was mixed with concentrated sulphuric acid (30 c.c.) at 60°. The temperature rose to 73° and was maintained at that for 3 minutes; the deep red solution was then poured on ice and extracted with chloroform. After being washed with sodium carbonate solution, the extract was dried over anhydrous potassium carbonate

and the solvent removed; the colourless gum obtained soon crystallised and separated from very dilute methyl alcohol, on long standing, in almost colourless prisms, m. p. 90—91° (Found: C, 69·6; H, 6·8. $C_{12}H_{14}O_3$ requires C, 69·9; H, 6·8%).

This *hydrindone* is very soluble in organic solvents with the exception of petroleum. The *oxime*, prepared by the action of hydroxylamine hydrochloride and potassium acetate on an alcoholic solution of the hydrindone, is readily soluble in methyl alcohol and separates, on the addition of water, as a felted mass of colourless elongated prisms, m. p. 128—129° with previous softening (Found: N, 6·4. $C_{12}H_{15}O_3N$ requires N, 6·3%). The iso*nitroso*-derivative was prepared by the action of methyl nitrite on an alcoholic solution of the hydrindone containing a little hydrochloric acid. It separated from methyl alcohol, in which it was rather sparingly soluble, in faintly lemon-coloured prisms, m. p. 225—226° (decomp.) (Found: N, 5·6. $C_{12}H_{13}O_4N$ requires N, 6·0%).

6-*Bromo*-β-*veratrylbutyric Acid* (X).—β-Veratrylbutyric acid (75 g.) was dissolved in glacial acetic acid (150 c.c.) and acetic anhydride (50 c.c.) at 0° and mechanically stirred while bromine (55 g.) in glacial acetic acid (50 c.c.) was slowly added. The product was poured into water containing a little sulphurous acid. The almost colourless oil (100 g.) obtained gradually solidified; after being washed, it was dried in a desiccator and a portion was crystallised from acetic acid and a little water, separating in colourless stout prisms, m. p. 106—107° (Found: C, 47·5; H, 5·0. $C_{12}H_{15}O_4Br$ requires C, 47·5; H, 5·0%). This *bromo-acid* is very soluble in organic solvents with the exception of petroleum and may be crystallised from a mixture of this and benzene.

4-*Bromo*-6 : 7-*dimethoxy*-3-*methyl*-1-*hydrindone* (XI).—6-Bromo-β-veratrylbutyric acid (10 g.) was treated with concentrated sulphuric acid (50 c.c.) at 75° for 5 minutes and the orange-red solution was then poured on ice and extracted with chloroform. After being washed with sodium carbonate solution, the extract was dried over anhydrous potassium carbonate, and the solvent removed. The light green gum obtained partly crystallised when rubbed with a glass rod. After draining on porous porcelain and several crystallisations from dilute methyl alcohol, the *bromohydrindone* was obtained in lemon-coloured, flat prisms (2 g.), m. p. 82—83° (Found: C, 50·5; H, 4·6. $C_{12}H_{13}O_3Br$ requires C, 50·5; H, 4·6%). The *oxime* separated from methyl alcohol in stout prisms, m. p. 187—188° (Found: N, 4·5. $C_{12}H_{14}O_3NBr$ requires N, 4·7%).

4-*Bromo*-2-iso*nitroso*-6 : 7-*dimethoxy*-3-*methyl*-1-*hydrindone* (XII).—A solution of the bromohydrindone (5 g.) in methyl alcohol (30 c.c.) and concentrated hydrochloric acid (2 c.c.) was saturated

with methyl nitrite, the temperature being maintained at 35°. The yellow solution obtained slowly deposited crystals of the iso*nitroso*-derivative, which separated from alcohol, in which it was but slightly soluble, in small, pale yellow, elongated prisms (3·5 g.), m. p. 217° (decomp.) (Found: N, 4·3. $C_{12}H_{12}O_4NBr$ requires N, 4·4%). The acid mother-liquor, on being concentrated in a vacuum, deposited a crystalline substance (1 g.), which separated from methyl alcohol in colourless prisms, m. p. 155—156°, but was not further examined.

6-*Bromo*-3 : 4-*dimethoxy*-α-*methylhomophthalic Anhydride* (XV). —The *iso*nitroso-derivative (3·7 g.) was dissolved in water (25 c.c.) and sodium hydroxide (1·7 g.), toluene-*p*-sulphonyl chloride (2·7 g.) added to the deep red solution, and the mixture well shaken. On raising the temperature gradually to 50°, all went into solution, and at 60° the liquid became colourless. It was cooled, filtered, and acidified and the colourless syrupy 6-bromo-2-carboxy-3 : 4-dimethoxy-α-phenylpropionitrile (XIII), which did not crystallise, was extracted with ether. After removal of the solvent, the gummy nitrile was gently boiled with aqueous sodium hydroxide (50 c.c. of 8%) for 3 hours or until evolution of ammonia could no longer be detected. The filtered and well-cooled solution deposited, on addition of hydrochloric acid, crude 6-bromo-3 : 4-dimethoxy-α-methylhomophthalic acid (XIV) as a sticky mass; this was extracted with ether, and the ethereal solution dried over anhydrous sodium sulphate and evaporated. The colourless gummy acid was refluxed on the steam-bath with excess of acetyl chloride for ½ hour, the excess of acetyl chloride removed under diminished pressure, and the pale yellow *anhydride* (XV) crystallised from dry benzene, separating in minute, colourless, flat prisms (2·8 g.), m. p. 128—129° (Found: C, 45·7; H, 3·5. $C_{12}H_{11}O_5Br$ requires C, 45·7; H, 3·5%).

3 : 4-*Dimethoxy*-α-*methylhomophthalic Anhydride* (XVII).—The bromo-anhydride just described (2 g.) was dissolved in a little dilute aqueous sodium hydroxide, and the yellow solution warmed for a few minutes on the steam-bath until colourless. It was then diluted with water (100 c.c.) and heated on the steam-bath with sodium amalgam (100 g. of 4%) for 6 hours until a small filtered test portion showed only a faint cloudiness on treatment with hydrochloric acid. The whole was then acidified, extracted several times with ether, saturated with ammonium sulphate, and again repeatedly extracted, and the combined extracts were carefully dried over anhydrous sodium sulphate. The colourless gummy 3 : 4-dimethoxy-α-methylhomophthalic acid remaining after evaporation of the ether was refluxed with excess of acetyl chloride for ½ hour. After removal of the excess of acetyl chloride under diminished pressure,

the pale brown 3 : 4-*dimethoxy*-α-*methylhomophthalic anhydride* (XVII) was dissolved in boiling dry benzene and the solution was decolorised with norite and concentrated; the anhydride then separated in colourless prisms (1·2 g.), m. p. 131—133° (Found: C, 60·8; H, 5·1. $C_{12}H_{12}O_5$ requires C, 61·0; H, 5·1%).

6 : 7 : 3′ : 4′-*Tetramethoxy*-9-*methyl*-2′-*carbomethoxy*-3 : 4-*dihydroprotopapaverine* (XIX).—3 : 4-Dimethoxy-α-methylhomophthalic anhydride (1·5 g.) and β-veratrylethylamine (1·3 g.) were refluxed together in dry benzene (30 c.c.) for 2 hours. The well-cooled, pale yellow solution was extracted with aqueous sodium hydroxide (25 c.c. of 5%) and the orange-yellow alkaline liquid was extracted with ether and then made acid with hydrochloric acid. The precipitated, colourless, gummy *N*-β-veratrylethyl-3 : 4-dimethoxy-α-methylhomophthalamic acid (XVIII) was dried in a desiccator, and the brittle amorphous solid obtained, which could not be crystallised, was dissolved in a solution of sodium bicarbonate (0·7 g.) in water (10 c.c.). Addition of silver nitrate (3 g. in 10 c.c. of water) to the filtered solution precipitated the silver salt, which was washed once with water, dried in a vacuum over phosphoric oxide, and refluxed with methyl iodide (3 c.c.) in dry ether (50 c.c.) for 12 hours. The filtered ethereal solution was evaporated to dryness and the crude gummy methyl ester (2 g.) was gently boiled with freshly distilled phosphorus oxychloride (20 c.c.) for 10 minutes. The excess of oxychloride was removed by distillation under reduced pressure, the residue warmed with water (60 c.c.), and the clear solution made alkaline with sodium hydroxide; the orange amorphous precipitate which then separated crystallised from methyl alcohol in colourless prisms (1·1 g.); m. p. 136—137° with previous softening (Found: C, 66·7; H, 6·5. $C_{23}H_{27}O_6N$ requires C, 66·8; H, 6·5%). This *substance*, the properties of which show that it has the constitution (XIX), is soluble in dilute acids and precipitated unchanged by alkalis. It does not appear to be readily hydrolysed by methyl-alcoholic sodium hydroxide.

Oxydehydrocorydaline (XX).—When the methyl ester (XIX) just described (1 g.) was heated in a test-tube at 150—170° for 10 minutes, the colourless substance, after melting, turned yellow, evolution of methyl alcohol could be detected, and the residue became quite dry and apparently crystalline. The substance was dissolved in much boiling alcohol, in which it was very sparingly soluble; almost colourless, cube-like prisms separated on slow cooling, and a further quantity was obtained by concentrating the mother-liquor. After recrystallisation, the substance (0·5 g.) melted at 235—236°, and micro-analysis gave C, 69·0; H, 6·0, whereas $C_{22}H_{22}O_5N$ requires C, 69·2; H, 6·0%. This substance is insoluble in dilute alkalis or

alkalis, but dissolves readily in warm glacial acetic acid, and crystallises unchanged on the addition of water. It is soluble in sulphuric acid (50%), on warming, and the addition of a drop of concentrated nitric acid produces an almost black coloration, which changes to deep wine-red in a few minutes and then very slowly fades to yellow. There could be no doubt that this substance, which has properties so very similar to those of oxyberberine, is oxydehydrocorydaline (XX), and this view was confirmed, as has already been explained in the introduction (p. 2994), by direct comparison with a specimen of oxydehydrocorydaline from corydaline for which we are indebted to Dr. von Bruchhausen.

CCCXCIV.—*The Dependence of Rotatory Power on Chemical Constitution. Part XXXIII. The Resolution of* dl-m-*Carboxyphenyl Ethyl Sulphoxide and of* dl-m-*Carboxyphenylethylsulphine*-p-*toluenesulphonylimine.*

By JOSEPH HOLLOWAY, JOSEPH KENYON, and HENRY PHILLIPS.

THE resolution of the sulphoxide (I) and the sulphilimine (II) derived from *m*-carboxyphenyl ethyl sulphide substantiates the

(I) $\bar{O}—\overset{+}{S}<\begin{matrix}C_6H_4\cdot CO_2H\\C_2H_5\end{matrix}$ $\qquad$ $C_6H_4Me\cdot SO_2\cdot\bar{N}—\overset{+}{S}<\begin{matrix}C_6H_4\cdot CO_2H\\C_2H_5\end{matrix}$ (II)

results previously recorded (Harrison, Kenyon, and Phillips, J., 1926, 2079; Clarke, Kenyon, and Phillips, J., 1927, 188), which provided independent experimental evidence for the existence of semipolar double bonds.

The brucine salt of m-*carboxyphenyl ethyl sulphoxide*, after recrystallisation from ethyl alcohol until no further increase in rotatory power occurred, had $[\alpha]^{25°}_{5461}$ +70° in chloroform solution. It gave on decomposition with aqueous sodium hydroxide *d*-*m*-carboxyphenyl ethyl sulphoxide the specific rotatory powers of which are recorded in Table I.

The quinidine salt of the *dl*-sulphoxide, after recrystallisation from benzene, containing a little ethyl alcohol, until constancy of rotatory power—$[\alpha]^{25°}_{5461}$ +102°—was reached, gave on decomposition *l*-*m*-carboxyphenyl ethyl sulphoxide with $[\alpha]^{25°}_{5461}$ −232° in chloroform solution. The satisfactory agreement between the specific rotatory powers of the two enantiomorphs is good evidence that both were obtained optically pure.

* This solution was prepared by diluting to the required volume a solution of a known weight of the *d*-sulphoxide in the calculated quantity of standard potassium hydroxide.

The specific rotatory powers of *d-m*-carboxyphenyl ethyl sulphoxide under the experimental conditions employed are all greater than those of *d-m*-carboxyphenyl methyl sulphoxide (Harrison, Kenyon, and Phillips, *loc. cit.*), but in common with the optically active sulphoxide previously described it exhibits complex rotatory dispersion and gives solutions which show no sign of mutarotation even after standing for several months. It can be concluded that the *dl*-sulphoxide is a racemic compound, since its m. p. and its solubilities in various solvents differ widely from those of the optically active enantiomorphs. The *d*-sulphoxide on oxidation yields optically inactive m-*carboxyphenylethylsulphone*.

Under experimental conditions which lead to the replacement of the oxygen atom of the *d*-sulphoxide, racemisation occurs. For example, when the sulphoxide is treated in chloroform solution with hydrogen bromide, the resulting m-*carboxyphenyl ethyl sulphide dibromide* is optically inactive. Further, the rotatory power of a solution of the *d*-sulphoxide in 1·1*N*-hydrobromic acid remains practically unchanged during 1588 hours, but in the same time, owing presumably to more complete reversible replacement of the oxygen atom by bromine, a similar solution in 3·3*N*-hydrobromic acid loses its optical activity as shown in Table II.

TABLE II.

Specific rotatory powers of *d-m*-carboxyphenyl ethyl sulphoxide in 3·3*N*-hydrobromic acid solution at 25°.

Specific rotatory power of the sodium salt of *l-m*-carboxyphenylethylsulphine-*p*-toluenesulphonylimine.

Water *	1·7950	—	—	318	363	662

* This solution was prepared by diluting to the required volume a solution of a known weight of the *l*-sulphilimine in the calculated quantity of standard sodium hydroxide.

The more soluble portions of the brucine salt on decomposition gave a sulphilimine with $[\alpha]_{5461}$ +270°. This sulphilimine was combined with strychnine, and the strychnine salt crystallised repeatedly from ethyl alcohol until its rotatory power remained unchanged. It then had $[\alpha]^{25°}_{5461}$ +152° and on decomposition gave *d-m*-carboxyphenylethylsulphine-*p*-toluenesulphonylimine with $[\alpha]^{25°}_{5461}$ +373° in ethyl-alcoholic solution.

The physical properties of both optically active and the inactive sulphilimines are similar, in marked contrast to the wide divergence between the physical properties of the optically active and inactive sulphoxides. Hence the *dl*-sulphilimine is probably a mixture of the two enantiomorphs and not a racemic compound. The specific rotatory power of the optically active sulphilimine is but slightly influenced by solvents and remains unchanged when the solutions are kept for several months. The rotatory dispersion is less complex than that exhibited in corresponding solvents by the sulphoxide: in ethyl-alcoholic solution the sulphilimine exhibits simple rotatory

dispersion, since a straight line is obtained when $1/\alpha$ is plotted against λ^2.

d + *dl-m*-Carboxyphenylethylsulphine - *p* - toluenesulphonylimine was converted by the action of dilute hydrochloric acid into a mixture of *p*-toluenesulphonamide, *m*-carboxyphenyl ethyl sulphide, and *dl-m*-carboxyphenyl ethyl sulphoxide, and with hydrogen peroxide the *dl*-sulphilimine gave as sole products *p*-toluenesulphonamide and *m*-carboxyphenylethylsulphone.

EXPERIMENTAL.

Preparation and Resolution of dl-m-*Carboxyphenyl Ethyl Sulphoxide.*

m-*Ethylthiolbenzoic Acid.*—*m*-Thiolbenzoic acid (78 g.), prepared by the reduction of *m*-chlorosulphonylbenzoic acid (Smiles and Stewart, J., 1921, **119**, 1792), was dissolved in sodium hydroxide solution (1000 c.c. of 10%) and added to a solution of ethyl *p*-toluenesulphonate (200 g.) in ethyl alcohol (500 c.c.). The mixture was heated under reflux on a steam-bath until a sample remained clear on dilution with water (6—8 hrs.). m-*Ethylthiolbenzoic acid*, precipitated from the cold reaction mixture by hydrochloric acid, was recrystallised twice from aqueous alcohol, from which it (73 g.) separated as shining leaflets, m. p. 99—100° (Found: equiv., by titration, 181. $C_9H_{10}O_2S$ requires equiv., 182).

dl-m-*Carboxyphenyl Ethyl Sulphoxide.*—*m*-Ethylthiolbenzoic acid (78 g.) and 2*N*-nitric acid (780 c.c.) were heated on a steam-bath until solution was almost complete and the evolution of nitrous fumes had ceased. The cold filtered solution was extracted several times with chloroform. The dl-m-*carboxyphenyl ethyl sulphoxide* obtained on evaporation of the dried chloroform extract was crystallised from either benzene or a mixture of chloroform and ligroin; it (52 g.) then had m. p. 104—106° (Found: C, 54·6; H, 5·1; S, 16·2; equiv., by titration, 199. $C_9H_{10}O_3S$ requires C, 54·5; H, 5·0; S, 16·1%; equiv., 198). It is moderately easily soluble in hot water, more easily soluble in warm alcohol, acetone, or chloroform, and fairly readily soluble in warm benzene, cold chloroform, or cold alcohol.

d-m-*Carboxyphenyl Ethyl Sulphoxide.*—When a solution of the *dl*-sulphoxide (27·5 g.) and brucine (55 g.) in hot ethyl alcohol (50 c.c. of 99%) was allowed to cool, the brucine salt, m. p. 98—101°, separated as rosettes of needles. After five recrystallisations from alcohol, subsequent recrystallisation produced no further change in the rotatory power of the salt, which then had m. p. 125—126° (after desiccation for 3 days) and $[\alpha]_{5461}$ +69° (c = [illegible], $l = 2$) in chloroform solution.

The brucine salt was decomposed with dilute sodium hydroxide

solution, the liberated brucine removed by filtration, and the filtrate acidified and extracted three times with chloroform. *d-m*-Carboxyphenyl ethyl sulphoxide, obtained from the dried chloroform extract, set to a hard mass of crystalline needles, m. p. 71°, and $[\alpha]_{5461}^{25°}$ +236° ($l = 2$, $c = 2{\cdot}230$) in chloroform solution.

l-m-*Carboxyphenyl Ethyl Sulphoxide*.—The *dl*-sulphoxide (15 g.) and quinidine (25 g.) were dissolved in hot benzene (150 c.c.) containing a few drops of ethyl alcohol. The quinidine salt (10 g.), which separated on standing, had m. p. 189°, $[\alpha]_{5461}$ +130° ($l = 2$, $c = 1{\cdot}25$) in chloroform solution. After five further recrystallisations, the optically pure salt was obtained with m. p. 198—199° and $[\alpha]_{5461}$ +102° ($l = 2$, $c = 1{\cdot}25$) in chloroform solution. *l-m*-Carboxyphenyl ethyl sulphoxide, obtained by the decomposition of this quinidine salt, had $[\alpha]_{5461}^{25°}$ −232°, $[\alpha]_{5790}^{25°}$ −207°, $[\alpha]_{4359}^{25°}$ −440° ($l = 2$, $c = 1{\cdot}25$) in chloroform solution.

m-*Carboxyphenylethylsulphone*.—The calculated quantity of perhydrol was added to a solution of *m*-ethylthiolbenzoic acid in aqueous potassium carbonate. When reaction was complete, the solution was cooled, filtered, and acidified with concentrated hydrochloric acid. The precipitated m-*carboxyphenylethylsulphone*, after crystallisation from hot water, had m. p. 162—164° (Found: equiv., by titration, 210. $C_9H_{10}O_4S$ requires equiv., 214), and was identical with the inactive sulphone, prepared in a similar manner from *d-m*-carboxyphenyl ethyl sulphoxide.

m-*Carboxyphenyl ethyl sulphide dibromide* separated as clusters of yellowish-red needles, m. p. 102°, when bromine (13 g.) was added to *m*-ethylthiolbenzoic acid (9 g.) in carbon disulphide (100 c.c.) (Found: Br, 45·3. $C_9H_{10}O_2SBr_2$ requires Br, 46·8%). Its bromine content decreases on exposure to air.

Preparation and Resolution of dl-m-*Carboxyphenylethylsulphine*-p-*toluenesulphonylimine*.

dl-m-*Carboxyphenylethylsulphine*-p-*toluenesulphonylimine*.—To a solution of *m*-ethylthiolbenzoic acid (110 g.) in warm alcohol (550 c.c.), made just alkaline to phenolphthalein by the addition of 3*N*-sodium hydroxide, chloramine-T (197 g.; 1·1 mols.) in warm water (550 c.c.) was added, and the mixture heated under reflux on a steam-bath for 2 hours. Dilute hydrochloric acid was added to the resulting solution when cold; dl-m-*carboxyphenylethylsulphine*-p-*toluenesulphonylimine* (100 g.) separated, and was obtained as small needles, m. p. 149°, by crystallisation from aqueous alcohol (Found: C, 54·8; H, 4·8; N, 3·9; S, 18·0; equiv., by titration, 349. $C_{16}H_{17}O_4NS_2$ requires C, 54·7; H, 4·8; N, 4·0; S, 18·2%; equiv., 351).

l-m-*Carboxyphenylethylsulphine*-p-*toluenesulphonylimine*.—To the *dl*-sulphonylimine (45 g.) in acetone (150 c.c.) containing a little ethyl alcohol, brucine (55 g.) was added, and the mixture warmed until solution was complete. The brucine salt, which crystallised in rosettes of fine needles, m. p. 160—161°, on cooling, was recrystallised from four successive quantities (about 150 c.c. in each case) of acetone containing a little alcohol. Subsequent recrystallisation produced no further alteration in the rotatory power of this salt, which then had m. p. 161°, and $[\alpha]^{20°}_{5461}$ −157° and $[\alpha]^{20°}_{4359}$ −287° ($l = 2$, $c = 1{\cdot}100$) in ethyl-alcoholic solution.

The brucine salt, dissolved in warm alcohol, was added to dilute hydrochloric acid, and a current of air drawn through the resulting clear solution. The l-m-*carboxyphenylethylsulphine*-p-*toluenesulphonylimine* which separated crystallised from alcohol in small prismatic needles, m. p. 149—150°, and had $[\alpha]^{25°}_{5461}$ −368° ($l = 2$, $c = 2{\cdot}543$) in ethyl-alcoholic solution (Found: C, 54·8; H, 4·8%).

Isolation of d-m-*Carboxyphenylethylsulphine*-p-*toluenesulphonylimine*.—(a) *By means of cinchonidine*. The *d* + *dl*-*m*-carboxyphenylethylsulphine-*p*-toluenesulphonylimine recovered from the alcohol–acetone mother-liquor from the first crystallisation of the brucine salt described above had $[\alpha]_{5461}$ +243°. That obtained from a second preparation of the brucine salt had $[\alpha]_{5461}$ +279°. These two lots (17·8 g.) of highly dextrorotatory sulphilimine, together with cinchonidine (14·9 g.), were dissolved in hot alcohol (500 c.c.). On cooling, the cinchonidine salt separated in bulky clusters of prismatic needles. It was recrystallised eight times from alcohol, but purification was rather slow and, towards the end, somewhat erratic. The almost optically pure *l*-cinchonidine *d*-*m*-carboxyphenylethylsulphine-*p*-toluenesulphonylimine obtained had m. p. 198—199° and $[\alpha]^{20°}_{5461}$ +50° ($l = 2$, $c = 1{\cdot}050$) in chloroform solution. On decomposition, as previously described, it gave *d* + *dl*-*m*-carboxyphenylethylsulphine-*p*-toluenesulphonylimine, m. p. 149—150°, $[\alpha]^{20°}_{5461}$ +364° ($l = 2$, $c = 2{\cdot}070$) in ethyl-alcoholic solution.

(b) *By means of strychnine*. On cooling a solution of the *d* + *dl*-sulphilimine (5·3 g.; $[\alpha]_{5461}$ +270°) and strychnine (5·0 g.) in alcohol (20 c.c.), the strychnine *d*-salt, m. p. 165°, separated. It was recrystallised ten times from alcohol (90—50 c.c.), its rotatory power then being constant, and was thus obtained as glistening prismatic needles, m. p. 174° (decomp.), $[\alpha]^{25°}_{5461}$ +152° ($l = 2$, $c = 0{\cdot}9566$) in ethyl-alcoholic solution. On decomposition with dilute sulphuric acid it gave *d*-*m*-carboxyphenylethylsulphine-*p*-toluenesulphonylimine, m. p. 150—151°, $[\alpha]^{25°}_{5790}$ +323°, $[\alpha]^{25°}_{5461}$ +373°, $[\alpha]^{25°}_{4359}$ [illegible] ($l = 2$, $c = 2{\cdot}3425$) in ethyl-alcoholic solution.

It is somewhat curious that, although strychnine forms a beauti-

fully crystalline salt—hard rosettes of fine needles—m. p. 162—164°, with the *dl*-sulphilimine, yet crystallisation of this salt from methyl alcohol effects no separation of the diastereoisomeric forms.

The Interaction of l + dl-m-*Carboxyphenylethylsulphine*-p-*toluenesulphonylimine and Hydrochloric Acid.*—The clear, deep red solution obtained by heating *l* + *dl*-sulphilimine (6 g.) with concentrated hydrochloric acid (18 c.c.) on a steam-bath for 5 minutes was neutralised with sodium carbonate solution, and the precipitated *p*-toluenesulphonamide (2·5 g., m. p. 138°) removed. The filtrate was acidified and the *m*-ethylthiolbenzoic acid liberated (1 g.), after crystallisation from aqueous alcohol, had m. p. 99°. By extraction five times with chloroform, the *m*-carboxyphenyl ethyl sulphoxide (1·0 g., m. p. 102—104°) remaining in the filtrate was isolated: 0·5 g. made up to 20 c.c. with chloroform gave a solution which was optically inactive when examined in a 2-dcm. tube in light of λ5461. The total yield of hydrolytic products was 75% of the calculated quantity.

The Interaction of dl-m-*Carboxyphenylethylsulphine*-p-*toluenesulphonylimine and Hydrogen Peroxide.*—A mixture of the *dl*-sulphilimine (4 g.) and perhydrol (35 c.c.), heated on a steam-bath with occasional shaking, gave a clear solution in 15 minutes. The crystalline material (3 g., m. p. indefinite) which separated on cooling was recrystallised from a small bulk of ethyl alcohol, glistening leaflets (1·5 g., m. p. 162—164°) of *m*-carboxyphenylethylsulphone being obtained. After dilution, the filtrate yielded a second crop of crystals (0·5 g.) which proved to be *p*-toluenesulphonamide, m. p. 138°.

The authors desire to express their thanks to the Government Grant Committee of the Royal Society for a grant which has helped to defray the cost of this investigation.

BATTERSEA POLYTECHNIC, S.W. 11. [*Received, September 20th*, 1928.]

CCCXCV.—*The Influence of Solvents on the Rotation of Optically Active Compounds. Part XXVI. The Optical Activity of Malic Acid in the Presence of Sodium Molybdate.*

By THOMAS STEWART PATTERSON and CHARLES BUCHANAN.

IN connexion with earlier work by one of us on the general problem of the rotation of optically active compounds, in which the influence of inactive solvents upon the rotation of active compounds was

studied, we thought it worth while to investigate some of those remarkable cases discovered by Biot and by Gernez in which substances such as borax and salts of molybdic and tungstic acids greatly influence the rotation of certain compounds like malic acid and tartaric acid. Perhaps the most remarkable effects of this character are those recorded by Gernez (*Compt. rend.*, 1889, **109**, 769), who studied solutions in which, to a fixed quantity of malic acid, gradually increasing amounts of sodium molybdate were added. He found the rotation to vary in such a manner that two minima of negative rotation and one positive maximum were developed, whilst between these three different concentrations were observed at which the rotation was zero. Gernez accounted for this behaviour by assuming that each maximum or minimum corresponds to the formation of a definite additive compound having a composition represented by the relative amounts of malic acid and sodium molybdate in solution at that particular concentration.

A summary of further work on this subject is given by Darmois (*J. Phys. Radium*, 1923, **4**, 49), who claims to have isolated three compounds: $(MoO_4)_2C_4H_6O_4Na_2,3H_2O$, with $[\alpha]_{5780}$ $+184°$ ($c = 0{\cdot}95$); $MoO_3,2C_4H_6O_5,2NaOH$, $[\alpha]_{5780}$ $-55{\cdot}1°$ ($c = 20$); and $MoO_3,2C_4H_6O_5,4NaOH$, for which no rotation value seems to be given.

The interesting phenomena described by Gernez have hitherto only been examined by means of light of one refrangibility and, with one exception, at the ordinary temperature,* and we deemed it of interest to investigate a number of these solutions at different temperatures and for different colours of light, especially for those concentrations at which the rotation changes from a positive to a negative value through zero, and *vice versa*, with increasing concentration of molybdic acid.

Preparation of Solutions.—The malic acid used was recrystallised from water and made thoroughly anhydrous. It had m. p. 100—103°, $[\alpha]^{17°}_{5790}$ $-1{\cdot}99°$ (1·861 g. in 20 c.c. of water); Gernez found $-2{\cdot}0°$ at the same temperature for *sodium* yellow (λ 5890).

Our first series of solutions was made up to correspond to those of Gernez, who used 1·1166 g. of malic acid in 12 c.c. of water. A

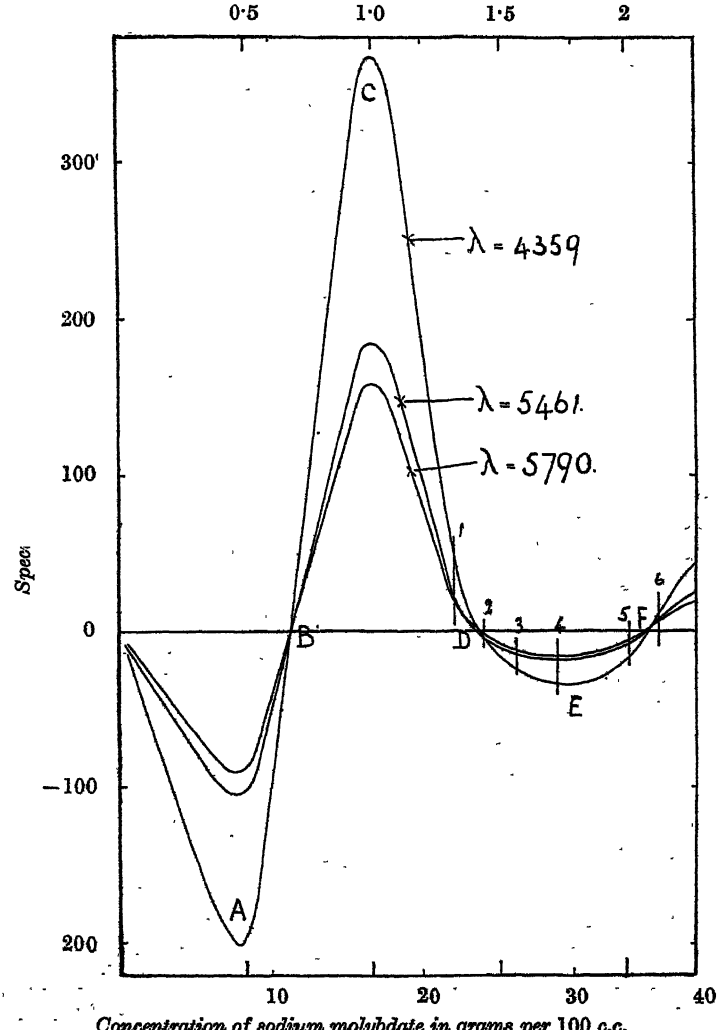
* Grossman and Pötter (*Z. physikal. Chem.*, 1906, **56**, 577) examined solutions containing malic acid and sodium molybdate up to temperatures of 95° and concluded that various complexes are formed, some dextro and some lævo, which on dilution decompose, yielding a complex of one molecule of Na_2MoO_4 and one molecule of malic acid. The work to be described, however, shows that above 60° such solutions undergo permanent change. They turn blue, and on cooling the rotation does not revert to its original value. Darmois (*loc. cit.*, pp. 63, 69) states that he used three different colours of light, but he records only dispersion ratios.

solution of malic acid in water was prepared of as nearly as possible 18·61 g. in 100 c.c. of solution, and its strength determined accurately by titration. Various quantities of sodium molybdate ($Na_2MoO_4,2H_2O$; recrystallised from water) were weighed into a 20 c.c. graduated flask to which 10 c.c. of the malic acid solution were added, and the solution was made up to 20 c.c. with water. The rotation of each solution was then examined for several colours of light and usually at different temperatures. The specific rotation was calculated relative to the amount of malic acid in the solution: $[\alpha] = 100\alpha/ldp$, where p = g. of malic acid per 100 g. of solution, or $[\alpha] = 100\alpha/lc$, where c = g. of malic acid per 100 c.c.

Fig. 1* shows the specific rotation for three colours of light at 17° plotted relative to *concentration of sodium molybdate*, the quantity of malic acid present remaining, of course, constant throughout.

The specific rotation of the malic acid solution without addition is so small that it can hardly be indicated on the diagram, but the addition of sodium molybdate increases the negative rotation very rapidly, and almost linearly, for all three colours of light, until the first minimum is reached with the addition of a quantity of sodium molybdate corresponding to approximately 0·5 mol. per mol. of malic acid present in the solution (*A* in Fig. 1). On further addition of molybdate the rotation then rapidly becomes less negative and reaches zero at a concentration of sodium molybdate corresponding to about 0·7 mol. per mol. of malic acid. Zero rotation is not reached, however, at exactly the same concentration of molybdate for each colour of light; the three curves do not all intersect on the line of zero rotation (*B* in Fig. 1).

With further addition of molybdate the rotation rapidly rises again, almost linearly, and reaches a positive maximum at or near a concentration of 1 mol. of molybdate per mol. of malic acid (*C* in Fig. 1). The rotation then rapidly diminishes, passing through zero rotation at *D*, where the concentration of molybdate is 1·4 mols. per mol. of malic acid, but it is difficult to decide whether the zero for all three colours is at the same concentration. The three curves appear to intersect in a region where the rotation has a slight negative value of about −4°; the diagram does not show this very well. With further addition of molybdate, a second minimum, *E*, is reached at a concentration of about 1·75 mols. of molybdate to 1 mol. of acid and, later, a third passage through zero rotation takes place at a concentration of about 2·07 mols. of molybdate to 1 of acid. The rotation then increases steadily until no more molybdate can be got into solution.



* To avoid confusion we have not indicated the individual experimental data on the diagrams.

These phenomena are very difficult to account for. It is easy to say that various compounds are formed in solution between the malic acid and the molybdate; but even on this hypothesis it is

FIG. 1.

Malic acid: c = 9·3; t = 17°.

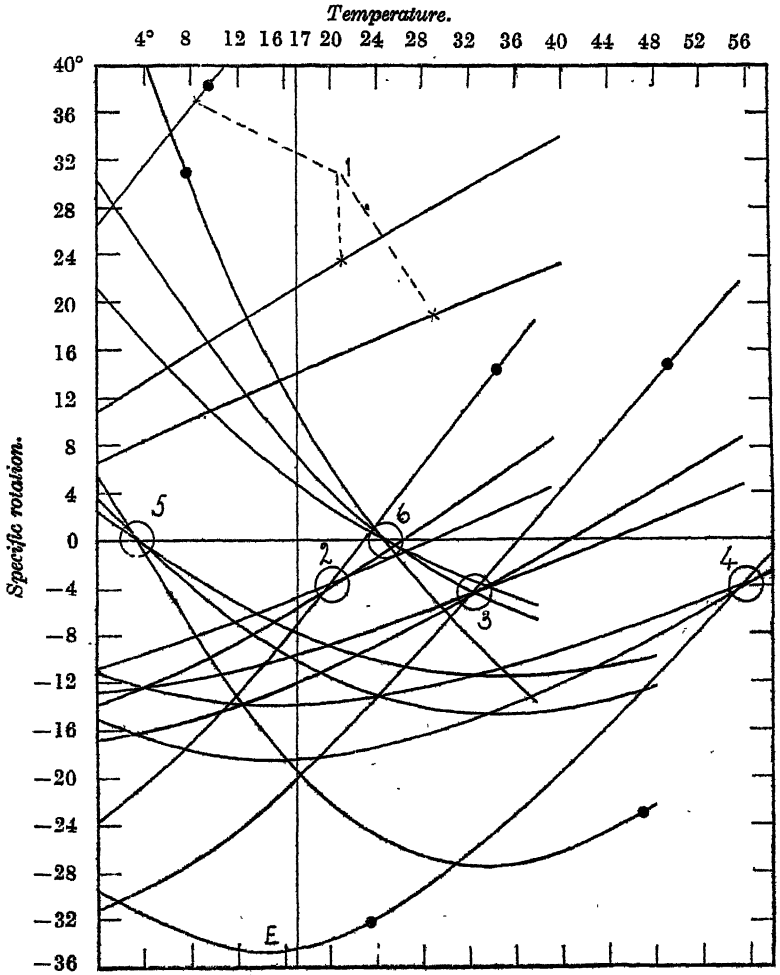
Concentration of sodium molybdate in molecules per molecule of malic acid.

difficult to give any consistent explanation of the phenomena. It might seem that at least four different kinds of combination must be postulated, with a reversal of sign of rotation between

form. Any discussion of the matter can only be undertaken by making so many quite arbitrary assumptions that for the present we do not propose to enter on it. The strongest argument in favour of this idea is that compounds of malic acid and sodium molybdate can be isolated in the solid form, Darmois claiming to have isolated three, as already mentioned. An alternative suggestion is that the sodium molybdate produces this effect by ordinary solvent action, and to show that this is not utterly improbable we may point to the facts that (1) salts such as barium chloride, potassium bromide, ammonium sulphate, etc., have very powerful depressing effects upon the rotation of aqueous solutions of ethyl tartrate (J., 1912, **101**, 1834), and (2) ethyl tartrate dissolved in benzene, in toluene and in *o*- and *m*-xylene apparently exhibits in dilute solution both a maximum and a minimum value in a manner not altogether unlike this, although, of course, in very different degree (J., 1902, **81**, 1099).

We wished particularly to examine the rotations of solutions in the neighbourhood of the points *B*, *D*, and *F* (Fig. 1) as regards the effect of temperature change, since from our previous work we should have expected, at these points, rapid change of rotation in correspondence with the very rapid change of rotation due to alteration in concentration of the sodium molybdate.

Fig. 2* shows some of these temperature–rotation curves which are numbered to correspond to the numbers shown in Fig. 1. It will be noticed that in all cases change of temperature does produce rapid alteration of rotation, and also that this alteration of rotation with change in temperature is consistent.



The general behaviour will be understood by considering the solutions marked 1, 2, 3, 4, 5, and 6 in Fig. 1. Of these, solution 2 may be first considered. The data shown on Fig. 1 are those for a temperature of 17° as marked by a vertical line in Fig. 2. When this solution is cooled, the rotation diminishes and the curves spread out from one another, but when it is heated above 17° the curves rapidly approach each other and intersect at, or very near, a point where the temperature is 20° and the specific rotation for the various colours is in the neighbourhood of −4·0°. It is difficult to decide whether the curves meet accurately at a point or over a slight range of temperature. On further heating of the solution, the rotation for all colours of light increases and the curves spread apart.

When solution 1 is heated the rotation for all the various colours of light rapidly increases, but clearly if it were possible to cool the solution much beyond zero, these curves would intersect one another

* It should be noted that only two of the curves in Figs. 1 and 2 are for the same wave-lengths. In Fig. 1, the third curve is for $\lambda = 5790$ (yellow) and in Fig. 2, for $\lambda = 6234$ (red). This is not likely, however, to cause any confusion.

at a lower temperature, which, since extrapolation would have to be carried out over a considerable range, cannot be estimated with accuracy.

FIG. 2.

Temperature–rotation curves for certain aqueous solutions of l-*malic acid and sodium molybdate, for* $\lambda = 6234, 5461, 4359$. *The curve for* $\lambda = 4359$ *is, in each case, marked with a black circle; the other two can then easily be identified.* *See also note on p.* 3010.

In solution 3 we find that, on heating from 0°, the rotation rapidly increases in such a way that the curves intersect one another at a temperature of approximately 33° and at a rotation value in the neighbourhood of −4°, after which the rotation continues to increase, the curves spreading out as in other cases.

The data shown for solution 4 (the point *E* in Fig. 1) lie at the minimum of the concentration curve, and are represented at *E* in Fig. 2, and are of a particularly interesting character. On cooling, the rotation of this solution diminishes (becomes more negative) to show a distinct minimum and then rises again on further cooling to zero temperature. On heating, the curves show a behaviour very similar to that exhibited by those already dealt with: the rotation rapidly increases, and again the various curves intersect one another at the same rotation as before, namely —4°, but at a temperature of 55°. Thus when the three solutions 4, 3, and 2 are heated, the curves for the different colours of light are found to intersect at practically the same rotation value, but at gradually diminishing temperatures.

In solution 5 we find, as in the last case, distinct minima in the curves, but here the data shown in Fig. 1 at 5 lie on the left of the minimum in Fig. 2, whereas for solution 4 they lie to the right (point *E*, Fig. 2). On cooling, the curves for solution 5 gradually approach one another and intersect at a temperature of about —4° and a rotation value in the neighbourhood of zero; on heating, the rotation diminishes and reaches a distinct minimum value, after which the curves rise again, but could not be followed to higher temperatures on account of the liability of the solution to decompose.

The temperature–rotation curves for solution 6 are also shown. In this case the rotation rapidly diminishes with rising temperature, and the curves intersect one another apparently over a slight range of temperature in the neighbourhood of zero rotation.

Thus, the behaviour throughout is entirely consistent; on heating the solutions 2, 3, and 4, the curves are made to intersect one another at practically the same rotation, —4°, but at different temperatures, *viz.*, 20°, 33°, and 55° respectively. It seems indisputable that, on heating, these solutions are brought into the condition represented on Fig. 1 at the point *D*, and, from analogy, it will probably be admitted that when solution 1 is cooled, its temperature–rotation curves would be caused to intersect at this same point. On the other hand, by cooling solution 5 and by heating solution 6, the curves are caused to intersect at a rotation value at or very close to zero, but at temperatures of 4° and 24° respectively, and this region of intersection is that represented at *F* in Fig. 1.

We had hoped that with one of these solutions, such as number 4, we should be able to demonstrate both of these regions of intersection of the temperature–rotation curves: that by heating the solution we should be able to reach the point *D* on Fig. 1 and, by cooling it, reach the point *F*, but in this we were disappointed, as it

is not possible to heat any of these solutions over a sufficient range of temperature.

It appears from this, however, that the behaviour of these solutions is closely similar to that of other simple active compounds dissolved in "indifferent" solvents, for it has been shown by one of us that, although the temperature–rotation curves of an active compound may be very greatly modified either by different solvents or by change of concentration in one solvent, yet the rotation value at which any two such curves intersect one another has, in general, one definite value, although it may occur at very different temperatures.

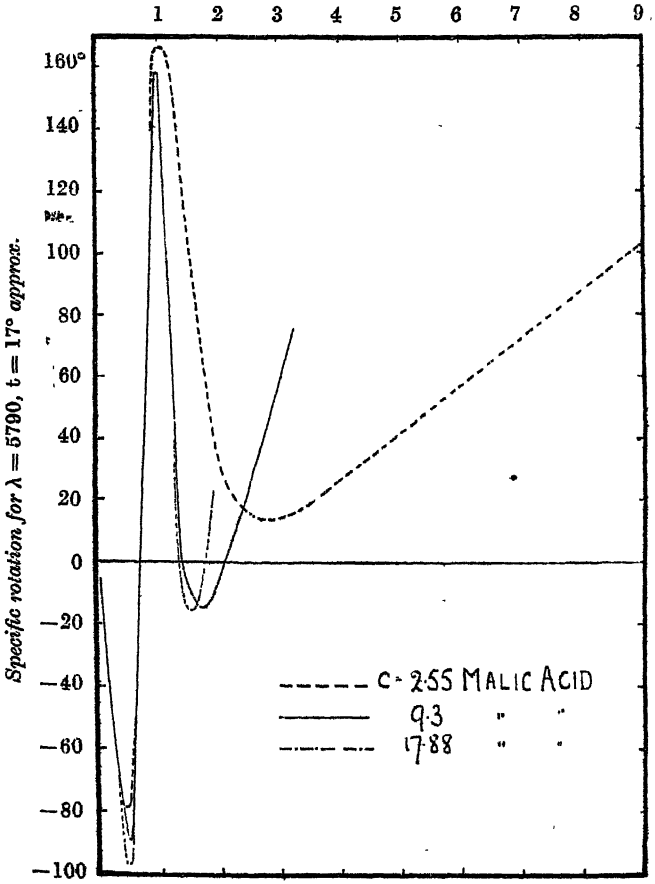
The data we have collected furnish interesting and unique material in connexion with the characteristic diagram. In a previous paper by one of us (J., 1916, **109**, 1202), it was suggested that in consequence of the apparently periodic character of the temperature–rotation curves for active compounds, "any given substance may very probably have several characteristic diagrams and several rational zeros. If these rational zeros are very different in value it might be possible readily to detect the trend of the two separate diagrams." And in a later paper (*Proc. Roy. Soc. Edinburgh*, 1918—19, **39**, 27) indications of the existence of two characteristic diagrams in the case of *iso*butyl dibenzoyltartrate were described. In the present instance, since there are four points (including the point of origin of the diagram) at which the rotation becomes zero, it might be possible to draw four separate characteristic diagrams. There should be one from the point of origin up to the region *A*; another from the region *A* through *B* to the region *C*; a third from the region *C* through *D* to the region *E*; and another from *E* through *F* onwards. Since the points of intersection lie so close to zero, it is not easy to distinguish clearly between these separate characteristic diagrams, but on account of the fact that the intersections at *D* and at *F* lie, quite definitely, (Fig. 2) at different rotation values, it is also certain that the two characteristic diagrams which could be drawn for these two regions of the curves are different. We do not wish to dwell upon the point now; we may have occasion to refer to it in connexion with later work. We may add, however, that in consequence of intersection taking place very near zero rotation in each case, dispersion ratios remain fairly constant throughout, the constancy being somewhat improved by calculating from the rational zero in each case.

If these curves are considered from the point of view of a combination of malic acid and sodium molybdate in solution, they might possibly be interpreted by supposing that heating the solutions has the effect of dissociating any compound which may be formed, and that cooling has the opposite effect.

The portion of the curve in the neighbourhood of the second minimum is possibly the most interesting on account of the comparatively easy recognisability of the two regions of intersection. We have not examined the other portions of the curve in so complete a fashion, but, except for solutions represented on the part of the curve from the origin up to *A*, it appears that heating the solutions causes a change of rotation similar to that obtained by travelling along the concentration curve to the left as in the cases referred to above. For solutions from the origin up to *A*, a different behaviour is noticeable: on heating such solutions it might be expected from the previous observations that the rotation should diminish, whereas the opposite takes place—the rotation increases slightly.

Since the number of colours of light used by us is only small, we have not examined very specially the dispersion curves for these solutions—they seem to us much like these for most other active compounds. By plotting λ^2 against $1/\alpha$ we find for the solution indicated by 1 in Figs. 1 and 2, at 16° and 36°, an approximately linear relationship, but for 2 and 3 at zero, 4 at 17° and 5 at 30°, this is not the case.

The foregoing experiments were carried out with practically the same concentration of malic acid as was used by Gernez, the concentration of sodium molybdate being increased as far as possible. In order to increase the proportion of molybdate to malic acid to a still greater extent, we used a more dilute solution of malic acid ($c = 2{\cdot}55$ g./100 c.c. of solution), the rotation being examined for three different colours of light at approximately 20°. The results for mercury yellow (λ 5790) are shown in Fig. 3. The curve obtained shows that the variation of the rotation for this proportion of malic acid with gradual increase in the quantity of molybdate present is, on the whole, similar to that previously described. The first minimum occurs very near the same position as before, but seems to have a slightly less negative value, whilst the first maximum has a slightly higher value. A greater difference is to be observed in the second minimum which, for this solution, has a positive instead of a negative value. There is no definite indication, however, of a second maximum although the quantity of molybdate to malic acid was more than twice as much as in the previous case.



We also examined a solution of greater concentration as regards malic acid, and its behaviour is also shown in Fig. 3. The curve obtained is, on the whole, very similar to the first one described, and, in general, it may perhaps be said that increase in concentration of the malic acid compresses the whole concentration curve towards the left of the diagram, increased dilution having the opposite effect.

Since these changes have been attributed to formation of com-

pounds of sodium molybdate and malic acid, we examined for comparison a solid compound obtained by dissolving 9 g. of malic acid and 8·1 g. of sodium molybdate in a small quantity of water, and then adding warm alcohol until a slight turbidity was produced. On standing, light crystals filled the liquid and were

FIG. 3.

Molecules $Na_2MoO_4,2H_2O$ *to* 1 *molecule* $C_4H_6O_5$.

filtered off, $[\alpha]_g^{17°}$ −48·55 (c = 2·5). On recrystallisation from aqueous alcohol, the rotation rose to −50·45° and remained constant on further recrystallisation, but analytical results agreed only approximately with the formula $2C_4H_6O_5,Na_2MoO_4$. A rough estimate of the change of rotation with concentration indicated that the specific rotation decreases on dilution.

Attempts were made to find an organic solvent for this compound,

but without success. The rotation was therefore observed in aqueous solution for six colours of light at different temperatures. The temperature–rotation curves showed no very characteristic peculiarity; the rotation increased in much the same way as for solutions in the neighbourhood of *A*, Fig. 1.

We thought it worth while also to ascertain whether, on mixing solutions of malic acid and of sodium molybdate, any gradual change of rotation with lapse of time—any lag—could be observed. In our first experiment, the two separate solutions were kept at room temperature for a considerable time, then mixed and immediately placed in the polarimeter. The rotation showed quite a considerable and steady change during about ½ hour. We found, however, that this was, in fact, a temperature effect. On mixing the two solutions there is a rise of temperature—which, of course, may indicate the formation of some compound—and, as the solution cooled, its rotation changed, in the manner of one of the curves in Fig. 2. If, after mixing, the solutions were quickly cooled to the original temperature by immersing the containing flask in water, no lag could be observed.

Experimental Data.

The colours of light used were the following and, to save space, will be denoted in the sequel by letters:

UNIVERSITY OF GLASGOW. [*Received, July 14th*, 1928.]

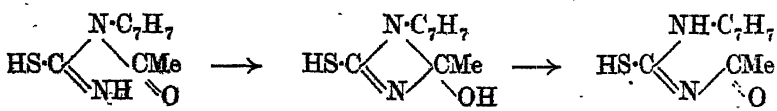
CCCXCVI.—*Aminobenzthiazoles. Part X. The Mobility of the 1-Amino-3-methylbenzthiazole System.*

By ROBERT FERGUS HUNTER and ERIC ROFE STYLES.

IN Part III (J., 1926, 1385) it was shown that rational syntheses of 1-aminobenzthiazole and of 1-imino-1 : 2-dihydrobenzthiazole led to a single individual which gave almost quantitatively the 1-imino-2-alkyl-1 : 2-dihydro-derivative on alkylation and 1-acetamidobenzthiazole on acetylation. On the basis of those experiments, the mobility of the symmetrical triad system in 1-aminobenzthiazole was regarded as being established.

That experimental evidence, however, is somewhat slender to carry the superstructure of the theories which have been suggested in Parts V to IX. Moreover, the criticism has still to be met, that the isolation of the second alkyl derivative of 1-aminobenzthiazole was left doubtful; for Pyman (J., 1923, **123**, 367, 3359) has shown that mobile open-chain amidines invariably react in two tautomeric forms on methylation. It was therefore decided to establish the mobility of a typical substituted 1-aminobenzthiazole by means of evidence of the symmetry type (Ingold and Piggott, J., 1922, **121**, 2381) and of the substitution type (*idem*, J., 1923, **123**, 1470) about which there could be no question. The example chosen was 1-amino-3-methylbenzthiazole (I ⇌ II).

(I.)  (II.)



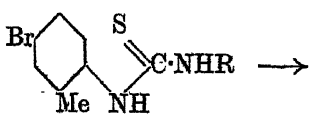
The symmetry test of mobility was first applied. By the rational syntheses mentioned below, 1-*acetamido*-3-*methylbenzthiazole* (III) and

1-*imino*-2-*acetyl*-3-*methyl*-1 : 2-*dihydrobenzthiazole* (IV) were prepared, and these yielded the same tautomeric base (I $\rightleftharpoons$ II) on hydrolysis. Moreover, (III) was obtained in almost quantitative yield by direct acetylation of 1-amino-3-methylbenzthiazole with acetic anhydride.

Under the usual conditions, bromination of stable acetyl-*o*-tolylthiocarbamide, C_7H_7·NH·CS·NHAc (Hugershoff, *Ber.*, 1899, **32**, 3649; Wheeler, *Amer. Chem. J.*, 1902, **27**, 270) readily produced a *tetrabromide* of 1-acetamido-3-methylbenzthiazole, which gave the expected base (III) on reduction with sulphurous acid. Bromination of labile acetyl-*o*-tolylthiocarbamide, C_7H_7·NAc·CS·NH_2, under carefully controlled conditions led to the production of a *tribromide* (compare Hunter, J., 1926, 1395), which gave the isomeric iminoacetyldihydrobenzthiazole (IV) on reduction.

When the temperature was allowed to rise, or when a considerable excess of bromine was employed, during the bromination of *labile* acetyl-*o*-tolylthiocarbamide, the product consisted, not of the expected iminoacetyldihydrobenzthiazole tribromide, but of the tetrabromo-addition compound obtainable by bromination of the isomeric *stable* acetyl-*o*-tolylthiocarbamide. This result was evidently due to conversion of the labile into the stable acetylthiocarbamide under the influence of bromine, similar to the isomerisation which these compounds are known to undergo under the influence of alkalis (Wheeler, *loc. cit.*), followed by thiazole ring formation in the usual way (Hunter and Soyka, J., 1926, 2958). This curious isomerisation may be explained by assuming the formation of an intermediate, unstable, four-membered, heterocyclic compound of the 1 : 3-dimethindiazine type obtained by Ingold and Piggott (J., 1922, **121**, 2797) by the additive union of suitable azomethines (compare also Ingold and Piggott, J., 1923, **123**, 2746; Ingold, J., 1925, **127**, 1141):

The substitution test completely supported the symmetry test of mobility (compare Ingold and Piggott, J., 1923, **123**, 1471), for methylation of the single individual (I $\rightleftharpoons$ II) gave rise to a mixture of 1-*methylamino*-3-*methylbenzthiazole* (V) and 1-*imino*-2 : 3-*dimethyl*-1 : 2-*dihydrobenzthiazole* (VI) containing about 1% of the former. (V and VI are III and IV, respectively, with Me in place of Ac.)



The addition of methyl iodide to mobile and to static amidines (Burtles and Pyman, J., 1923, **123**, 362; Pyman, *ibid.*, pp. 367, 3359) appears to indicate that the first action of methyl iodide on the former is one of direct addition to the double-bonded nitrogen atoms of both phases of the tautomeric system, with the production of isomeric methiodides which pass into the hydriodides of the methyl derivatives derived from the isomeric forms of the mobile individual:

$$\begin{array}{cccccccc} -[H]N\cdot C{:}N & & -[H]N\cdot C{:}N(MeI) & & -N{:}C\cdot N[H](MeI) & & -N{:}C\cdot NMe(HI) \\ \downarrow\uparrow & \longrightarrow & + & \longrightarrow & + & \longrightarrow & + \\ -N{:}C\cdot N[H] & & -(MeI)N{:}C\cdot N[H] & & -(MeI)N[H]\cdot C{:}N & & -(HI)NMe\cdot C{:}N \end{array}$$

The suggestion (Hunter, J., 1926, 1389) that iminomethyldihydrobenzthiazole is obtained from the iminodihydro-phase by direct replacement of the mobile hydrogen atom (compare von Pechmann, *Ber.*, 1897, **30**, 481; Lander, J., 1903, **83**, 320; Cohen and Marshall, J., 1910, **97**, 329) must therefore be modified (compare Young and Crookes, J., 1906, **89**, 59; Tschitschibabin and Konowalowa, *Ber.*, 1921, **54**, 814). The methylation of semi-cyclic amidines in which one of the nitrogen atoms of the triad system is part of an aromatic heterocyclic nucleus, as in aminothiazoles and α-aminopyridines, is evidently dependent on the aromatic conjugation of the system, a topic which will be more fully discussed in a future paper.

The bromo-addition compounds of 1-amino-3-methylbenzthiazole and its derivatives were reduced by hydriodic acid in acetic acid, but owing to the readiness with which they changed into bromo-substitution compounds it was impossible to estimate the labile bromine iodometrically.

The bromo-substitution compounds were shown to be 5-*bromo*-1-*alkylamino*-3-*methylbenzthiazoles* (VIII) by rational syntheses of the 1-amino-, 1-*n*-propylamino-, and 1-*n*-heptylamino-compounds from the corresponding *p*-bromo-*o*-tolylthiocarbamides (VII).

(VII.)  (VIII.)

EXPERIMENTAL.

(Tautomeric substances are named on the basis of the amino-formulæ.)

Synthesis of 1-*Amino*-3-*methylbenzthiazole from* 1-*Imino*-2-*acetyl*-3-*methyl*-1 : 2-*dihydrobenzthiazole* (IV).—A solution of 5·5 g. labile acetyl-*o*-tolylthiocarbamide (m. p. 140°) in 50 c.c. of chloro-

form was gradually treated at 0° with bromine (2·5 c.c.) in chloroform (7 c.c.). The liquid was rapidly filtered and kept for 10—15 minutes at about 0° in a vacuum. The yellow needles of the *tribromide* produced, m. p. 173° (decomp.), after drying in a vacuum (Found: Br, 53·5. $C_{10}H_{10}ON_2Br_2S,HBr$ requires Br, 53·8%), were suspended in sulphurous acid and treated with sulphur dioxide and thereafter with ammonia (*d* 0·880). The 1-*imino*-2-*acetyl*-3-*methyl*-1 : 2-*dihydrobenzthiazole* obtained crystallised from absolute methyl alcohol in pale yellow prisms, m. p. 170° (Found: N, 13·4; S, 15·5. $C_{10}H_{10}ON_2S$ requires N, 13·6; S, 15·5%). It was refluxed with 25% hydrochloric acid for 24 hours, and the cooled solution neutralised with ammonia. The 1-amino-3-methylbenzthiazole produced crystallised from alcohol in small white plates which, alone or mixed with a genuine specimen, melted at 136° (Found: S, 19·7. Calc.: S, 19·5%).

Synthesis from 1-*Acetamido*-3-*methylbenzthiazole*.—A suspension of stable acetyl-*o*-tolylthiocarbamide (m. p. 187°) (2 g.) in chloroform (15 c.c.) was slowly treated with bromine (2 c.c. in 3 c.c. of chloroform), and the resulting solution refluxed for 10 minutes. On cooling, a *tetrabromide* separated in orange needles, which were dried in a vacuum; m. p. 140° (decomp.) (Found: Br, 61·1. $C_{10}H_{10}ON_2Br_4S$ requires Br, 60·8%). 1-*Acetamido*-3-*methylbenzthiazole*, obtained from this by reduction with sulphurous acid, separated from ethyl acetate in lustrous needles, m. p. 258° (Found: N, 13·8; S, 15·7. $C_{10}H_{10}ON_2S$ requires N, 13·6; S, 15·5%); it was identical with the acetyl derivative obtained by boiling a solution of 1-amino-3-methylbenzthiazole in acetic anhydride for a few minutes. On hydrolysis with 25% hydrochloric acid, 1-amino-3-methylbenzthiazole was obtained and identified in the usual way.

Bromination of 1-acetamido-3-methylbenzthiazole (0·5 g. in 25 c.c. of chloroform; 0·6 c.c. of bromine) yielded an unstable *hexabromide*, which crystallised in glistening orange plates, m. p. 255—258° (decomp.; loss of bromine at about 130°) (Found: Br, 69·8. $C_{10}H_{10}ON_2Br_6S$ requires Br, 70·0%).

Synthesis from 1-*Amino*-3-*methylbenzthiazole Dibromide Hydrobromide*.—A suspension of 2 g. of *o*-tolylthiocarbamide in 16 c.c. of chloroform was treated with bromine (2 c.c. in 3 c.c. of chloroform); the thiocarbamide dissolved and a yellow precipitate separated and redissolved with evolution of heat and hydrogen bromide, the solution boiling spontaneously. After a few minutes' refluxing, the *dibromide hydrobromide* crystallised in large, lustrous, orange-yellow plates, m. p. 129° (decomp. with efferv.) [Found: Br, 59·9; Br (labile), 35·0. $C_8H_8N_2Br_2S,HBr$ requires Br, 59·3; Br (labile), 39·5%]. The low titration value is due to a certain

amount of the bromo-addition compound passing into 5-bromo-1-amino-3-methylbenzthiazole hydrobromide, a change which has been observed by Prof. R. W. West and his collaborators (private communication) in the case of perbromides of aromatic bases having a free *para* position (compare also Fries, *Annalen*, 1906, **346**, 128). The bromide dissolved in 80% alcohol, from which *5-bromo-1-amino-3-methylbenzthiazole hydrobromide* crystallised in small white needles, m. p. 280—290° (with charring) (Found: Br, 49·1. $C_8H_7N_2BrS,HBr$ requires Br, 49·4%). Treatment of the bromide with sulphurous acid and subsequent basification, however, gave a quantitative yield of 1-amino-3-methylbenzthiazole, m. p. 136°.

When prepared as above, in large crystals, the dibromide hydrobromide can be preserved in a sealed vessel for more than a year. Small crystals (having the same crystalline structure and m. p. as before), obtained by alteration in the conditions of concentration and separation, are sensitive to moisture; one specimen, on exposure to the laboratory atmosphere for 30 hours, was completely converted into *1-amino-3-methylbenzthiazole hydrobromide* (m. p. 220°), identical with the hydrobromide prepared by concentrating a solution of 1-amino-3-methylbenzthiazole in 20% hydrobromic acid; this crystallised in small needles, m. p. 220—222° (Found: Br, 32·0. $C_8H_8N_2S,HBr$ requires Br, 32·6%).

1-Amino-3-methylbenzthiazole Tetrabromide.—When a solution of 0·6 g. of 1-amino-3-methylbenzthiazole in 10 c.c. of chloroform was gradually treated with a solution of bromine (0·4 c.c. in 5 c.c. of chloroform) a *tetrabromide* was obtained in yellowish-brown prisms, m. p. 302° (loss of colour at 130—140°) (Found: Br, 65·9. $C_8H_8N_2Br_4S$ requires Br, 66·1%).

Methylation of 1-Amino-3-methylbenzthiazole and the Isolation of 1-Methylamino-3-methylbenzthiazole and of 1-Imino-2:3-dimethyl-1:2-dihydrobenzthiazole.—A mixture of 1-amino-3-methylbenzthiazole (3·5 g.) and methyl iodide (2·5 c.c.) was heated at 100° for 24 hours; the product was basified with ammonia and extracted with ether. The clear oil obtained after removal of the ether solidified on keeping (sometimes with considerable difficulty) and was fractionally crystallised from methyl alcohol. The first crop of crystals (about 0·02 g.) had m. p. 126°, which rose to 128° on recrystallisation and was unaltered by admixture with a genuine specimen of 1-methylamino-3-methylbenzthiazole prepared from *s-o*-tolylmethylthiocarbamide. (A mixture of 1-methylamino-3-methylbenzthiazole and 1-amino-3-methylbenzthiazole melted at 103—105° after softening at about 100°.) The more soluble [illegible] were dissolved in dilute methyl alcohol and the solution [illegible] concentrated at 16°/20 mm.; slightly impure 1-imino-2:3-dimethyl-

1 : 2-dihydrobenzthiazole then separated. This product had m. p. 83—84°, and m. p. 84—85° when mixed with a genuine specimen of 1-imino-2 : 3-dimethyl-1 : 2-dihydrobenzthiazole prepared from *as*-*o*-tolylmethylthiocarbamide; on recrystallisation the m. p. rose to 85—86°. The crude iminomethyl base was acetylated with acetic anhydride, and the product fractionally crystallised from alcohol; the bulk of the acetyl derivative consisted of the 1-acetimido-compound, which had m. p. 143°, and m. p. 145° when mixed with a genuine specimen of 1-acetimido-2 : 3-dimethyl-1 : 2-dihydrobenzthiazole. The mother-liquor from the acetylation, however, yielded a high-melting fraction, which, after recrystallisation, had m. p. 258° alone and when mixed with 1-acetamido-3-methylbenzthiazole.

Synthesis of 1-*Methylamino*-3-*methylbenzthiazole and of* 1-*Imino*-2 : 3-*dimethyl*-1 : 2-*dihydrobenzthiazole from the Corresponding Tolylmethylthiocarbamides.*—*o*-Tolylthiocarbimide was conveniently prepared in 80—90% yield (b. p. 238—240°/760 mm.) by refluxing quantities of 50 g. of *s*-di-*o*-tolylthiocarbamide with acetic anhydride (60 c.c.) for 10 minutes, being isolated by distillation in steam. *o*-Tolylthiocarbamide separated from 50% alcohol in glistening white needles, m. p. 160° (Dyson and George, J., 1924, **125**, 1703, recorded m. p. 156°).

s-*o*-*Tolylmethylthiocarbamide*, prepared by treating 5 g. of *o*-tolylthiocarbimide in 20 c.c. of absolute alcohol with a 30% excess of 33% methylamine in the same solvent, crystallised in glistening prisms, m. p. 161° (Found: S, 17·8. $C_9H_{12}N_2S$ requires S, 17·8%).

Bromination. A suspension of 2 g. of *s*-*o*-tolylmethylthiocarbamide in 10 c.c. of chloroform was treated with bromine (2 c.c. in 3 c.c. of chloroform) and the liquid was refluxed vigorously for 10 minutes and then concentrated in a vacuum at laboratory temperature; a *tetrabromide* crystallised in glistening red needles, m. p. 75° (decomp.) (Found: Br, 64·4. $C_9H_{10}N_2Br_4S$ requires Br, 64·2%). This compound was extremely sensitive to moist air and became yellow with loss of bromine on being exposed to the laboratory atmosphere for a few minutes.

When the bromination was carried out as above, but instead of being vigorously boiled, the solution was gently warmed on the steam-bath, a *tribromide* was obtained on concentration in a vacuum, which was probably the dibromide of a hydrobromide analogous to the compound obtained from *o*-tolylthiocarbamide itself. It formed glistening yellow prisms, m. p. 113° (Found: Br, 57·6. $C_9H_{10}N_2Br_2S,HBr$ requires Br, 57·3%). Attempts to determine its molecular weight in boiling chloroform (previously dried) were unsuccessful owing to dissociation with the liberation of free

bromine; on prolonged boiling in chloroform, hydrogen bromide also was liberated.

Both the tetrabromide and the tribromide dissolved in sulphurous acid, and on basification with ammonia, 1-*methylamino*-3-*methylbenzthiazole* separated, which crystallised from alcohol in lustrous needles, m. p. 130° (Found: N, 15·9; S, 18·2. $C_9H_{10}N_2S$ requires N, 15·7; S, 18·0%). The *acetyl* derivative, prepared as in the case of the isomeric iminodihydro-derivative, crystallised from alcohol–ethyl acetate in white needles, m. p. 133° (Found: S, 14·6. $C_{11}H_{12}ON_2S$ requires S, 14·5%).

as-o-*Tolylmethylthiocarbamide*.—Addition of methyl-*o*-toluidine in chloroform to thiocarbonyl chloride in water (compare Dyson and George, *loc. cit.*) gave a thiocarbamyl chloride which yielded uncrystallisable oils on treatment with ammonia. The thiocarbamide was therefore prepared by way of the thiocyanate. A solution of 10 g. of methyl-*o*-toluidine hydrochloride and 7 g. of potassium thiocyanate in 50 c.c. of water was heated for 3 hours on a steam-bath and then extracted with chloroform. The gum obtained by evaporation of the chloroform crystallised from methyl alcohol in small, white needles (3·5 g.), m. p. 107—108° (Found: S, 17·6%).

Bromination. The solution obtained from 1 g. of the thiocarbamide, 7 c.c. of chloroform, and 1 c.c. of bromine was refluxed for 3 minutes and then concentrated under reduced pressure at laboratory temperature. The orange bromo-addition compound obtained was dissolved in sulphurous acid and the filtered solution was basified and extracted with chloroform. The gum obtained by evaporation of the chloroform was dissolved in 80—90% methyl alcohol, and the solution concentrated at 16°/20 mm.; 1-*imino*-2 : 3-*dimethyl*-1 : 2-*dihydrobenzthiazole* crystallised in small white plates, m. p. 86° (Found: S, 18·1%). The *acetyl* derivative separated from alcohol in glistening plates, m. p. 147° (Found: S, 14·7%).

5-*Bromo*-1-*amino*-3-*methylbenzthiazole*.—A suspension of 0·9 g. of 5-bromo-*o*-tolylthiocarbamide (m. p. 194°. Dyson and George, J., 1924, **125**, 1706, give 186°) in chloroform (10 c.c.) was treated with bromine (1·1 c.c. in 1 c.c. of chloroform), and the solution refluxed for 10 minutes; a *dibromide hydrobromide* crystallised in orange, glistening prisms, which turned white at 130—140° but were unmelted at 250° (Found: Br, 66·3. $C_8H_7N_2Br_3S,HBr$ requires Br, 66·1%). On treatment with sulphurous acid and ammonia, it yielded 5-bromo-1-amino-3-methylbenzthiazole, which crystallised from alcohol in needles, m. p. 212°, and was identical with the base liberated from the hydrobromide obtained by the action of alcohol on 1-amino-3-methylbenzthiazole dibromide hydrobromide (Found: Br, 32·7. Calc.: Br, 32·9%).

s-o-*Tolyl*-n-*propylthiocarbamide* was prepared by warming a solution of *o*-tolylthiocarbimide in alcohol with 30% excess of *n*-propylamine. It separated from the solution after concentration and crystallised from alcohol in colourless prisms, m. p. 66° (Found: S, 15·5. $C_{11}H_{16}N_2S$ requires S, 15·4%).

1-n-*Propylamino*-3-*methylbenzthiazole Tetrabromide*.—A solution of 2 g. of *s-o*-tolyl-*n*-propylthiocarbamide in 10 c.c. of chloroform was treated with bromine (2 c.c. in 3 c.c. of chloroform), and the liquid vigorously refluxed for 10 minutes. On concentration in a vacuum the *tetrabromide* crystallised in brilliant red needles, m. p. 71° (efferv. at 130°) (Found: Br, 60·6. $C_{11}H_{14}N_2Br_4S$ requires Br, 60·8%). On treatment with sulphurous acid followed by ammonia the *base* was obtained; it crystallised from methyl alcohol in colourless needles, m. p. 62° (Found: S, 15·7. $C_{11}H_{14}N_2S$ requires S, 15·5%). The *hydrobromide* crystallised from ethyl acetate in prisms, m. p. 179° (decomp. after previous sintering) (Found: N, 10·0. $C_{11}H_{14}N_2S,HBr$ requires N, 9·8%).

The *acetyl* derivative formed colourless prisms, m. p. 61° (Found: S, 13·0. $C_{13}H_{16}ON_2S$ requires S, 12·9%).

When a solution of the tetrabromide in alcohol was diluted with a small quantity of water and concentrated, the *hydrobromide* of the bromo-substitution derivative separated; this crystallised from alcohol in tufts of fine white needles, m. p. 259° (Found: Br, 45·0. $C_{11}H_{13}N_2BrS,HBr$ requires Br, 43·7%).

s-5-*Bromo*-o-*tolyl*-n-*propylthiocarbamide*, prepared from 5-bromo-*o*-tolylthiocarbimide and *n*-propylamine, crystallised from methyl alcohol in slender white needles, m. p. 79° (Found: S, 11·4. $C_{11}H_{15}N_2BrS$ requires S, 11·2%).

5-*Bromo*-1-n-*propylamino*-3-*methylbenzthiazole*.—A solution of 1 g. of the bromotolylthiocarbamide in chloroform (10 c.c.) was refluxed with 1·2 c.c. of bromine for 15 minutes, cooled, and concentrated in a vacuum; an ill-defined bromo-addition compound separated (m. p. about 140°), which was reduced with sulphurous acid in the usual way. On recrystallisation from methyl alcohol, 5-*bromo*-1-n-*propylamino*-3-*methylbenzthiazole* was obtained, m. p. 82°, which was identical with the base (m. p. 82°) liberated from the last-mentioned hydrobromide (Found: Br, 28·3. $C_{11}H_{13}N_2BrS$ requires Br, 28·1%).

s-o-*Tolyl*-n-*heptylthiocarbamide* was prepared from *o*-tolylthiocarbimide and *n*-heptylamine and obtained as a viscous oil which gradually solidified in a vacuum. It crystallised from alcohol in large, colourless prisms, m. p. 98° (Found: S, 12·3. $C_{15}H_{24}N_2S$ requires S, 12·1%).

Bromination. When 2 g. of the heptylthiocarbamide were

brominated as in the case of the propyl compound, an unstable *hexabromide* was obtained in orange-red needles, m. p. 53° (sintering at 45°) (Found: Br, 64·4. $C_{15}H_{22}N_2Br_6S$ requires Br, 64·7%).

1-n-*Heptylamino*-3-*methylbenzthiazole* crystallised with difficulty from dilute methyl alcohol in white prisms, m. p. 57° (Found: S, 12·4. $C_{15}H_{22}N_2S$ requires S, 12·2%). The *acetyl* derivative formed stellate aggregates of needles, m. p. 73° (Found: S, 10·6. $C_{17}H_{24}ON_2S$ requires S, 10·5%).

The hexabromide dissolved in aqueous alcohol, giving the *hydrobromide* of the bromo-substitution derivative, which crystallised from alcohol in small, white plates, m. p. 220° (Found: Br, 37·6. $C_{15}H_{21}N_2BrS,HBr$ requires Br, 37·9%).

s-5-*Bromo*-o-*tolyl*-n-*heptylthiocarbamide* separated from dilute methyl alcohol in small white needles, m. p. 71° (Found: S, 10·1. $C_{15}H_{23}N_2BrS$ requires S, 9·3%).

5-*Bromo*-1-n-*heptylamino*-3-*methylbenzthiazole*.—The bromo-addition compound obtained from the bromotolylthiocarbamide was reduced and the 5-*bromo-base* produced was crystallised from dilute methyl alcohol; it had m. p. 75° alone and when mixed with the base (m. p. 75°) liberated from the preceding hydrobromide (Found: N, 8·6; Br, 23·7. $C_{15}H_{21}N_2BrS$ requires N, 8·2; Br, 23·5%).

The authors desire to express their gratitude to Professor J. F. Thorpe, F.R.S., for his kind interest in this work, to the Ramsay Memorial Fellowship Trust for the award of a Fellowship to one of them (R. F. H.), and to the Trustees of the Dixon Fund of the University of London for a grant which has helped to defray the cost of the materials.

CCCXCVII.—*The Interaction of Acids and Neutral Salts with Stannic Oxide and its Relation to Electrical Charge.*

By BHUPENDRA NATH GHOSH.

IN a previous paper (J., 1926, 2605) the inadequacy of the chemical theory to account for the development of an acid reaction when hydrated oxides of manganese are treated with solutions of neutral salts has been pointed out. It has also been shown how Mukherjee's theory of exchange adsorption (*Phil. Mag.*, 1922, [illegible] *J. Indian Chem. Soc.*, 1925, **2**, 191) satisfactorily explains [illegible]

According to this theory, the liberation of hydrogen ions is to be attributed to their displacement from the double layer by the kations in solution. Like the oxides of manganese, hydrated stannic oxide is also known to liberate acids when brought in contact with solutions of neutral salts. As early as 1812, from his investigations on the properties of stannic oxide prepared by various methods, Berzelius concluded that the substance is acidic in nature and exists in two forms—the α- and β-stannic acids. There is, however, considerable controversy over the actual existence of these different forms. The so-called α-acid may be prepared by the hydrolysis of stannic chloride or sulphate solution, or by the action of alkalis on them in the cold; the β-acid may be obtained by the action of concentrated nitric acid on metallic tin. The existence of definite hydrates of the two acids has also been reported by different investigators (compare Weiser, *J. Physical Chem.*, 1922, **26**, 654). Van Bemmelen ("Die Absorption," 1910, 59, 66) studied the dehydration of stannic oxide prepared by different methods, but his results do not confirm the existence of any definite hydrate of either acid. Mecklenburg (*Z. anorg. Chem.*, 1912, **74**, 207) measured the adsorption of phosphoric acid by stannic oxide prepared at different temperatures, and showed that by suitable variation of temperature it is possible to obtain samples having all grades of properties intermediate between the α- and the β-acid. Hence he concluded that both acids are colloidal in nature and that the difference in their properties is mainly due to the difference in the size of their particles, the α-acid being the more finely divided. Recently the question of the formation of stable hydrates of stannic oxides has again been raised by Willstätter and his collaborators (*Ber.*, 1924, **57**, 63). Their views have, however, been adversely criticised by Posnjak (*J. Physical Chem.*, 1926, **30**, 1073), who investigated the X-ray spectra of both the α- and the β-oxide. His results seem strongly to support the views of Mecklenburg, for the lines from the α-acid are wider than those from the β-acid, showing that the former possesses particles of finer size than the latter. In view of these controversies, the interaction of the α- and β-stannic oxides with electrolytes was investigated.

EXPERIMENTAL.

β-Stannic acid, prepared by the action of concentrated nitric acid on pure metallic tin, was washed by decantation with boiling water, and then with boiling conductivity water. The final washing was done under suction on a Buchner funnel until the p_H of the wash liquid rose to 6·0. When 5 g. of this sample were shaken with 100 c.c. of water its p_H changed from 6·4 to 5·8.

The α-acid was obtained by adding dilute ammonia to a solution of stannic chloride at 5°. The precipitate was washed several times with cold water, then with dilute nitric acid to remove the last traces of ammonia, and finally with conductivity water until the p_H of water in contact with it was 6·0.

Estimation of the Total Amount of Hydrogen Ions replaceable by the Kation of a Neutral Salt.—The α- and the β-oxide are known to form alkali salts of the form R_2O,SnO_2 and $R_2O,5SnO_2$, respectively (compare J. N. Friend, "Text Book of Inorganic Chemistry," Vol. V, p. 533). Since the samples that we are dealing with liberate hydrogen ions in contact with neutral salts, the question naturally arises as to what will be the final composition of the substances when all the hydrogen ions are removed by washing with the solution of a salt such as barium chloride. A definite weight of hydrated stannic oxide was therefore shaken with a known volume of saturated barium chloride solution (p_H 6·6) in a Pyrex-glass bottle for 15 minutes. After 24 hours as much as possible of the clear upper liquid was withdrawn and its p_H determined by either the *E.M.F.* or the indicator method. A measured volume of fresh barium chloride solution was added and the whole process repeated many times. With the progress of washing the p_H of the solution rose continuously as shown by the following data for 3 g. of the β-oxide (water content, 55%):

Vol. of solution added, c.c.	Vol. of solution withdrawn, c.c.	Final p_H of solution.
200	160	3·1
200	160	3·2
200	200	3·3

Towards the end, however, the hydrogen-ion concentration changed very slowly, and a small quantity of 0·2*N*-barium hydroxide was therefore added to bring the p_H of the solution to 6·6. In this way it is found that for every 6·6 g.-mols. of the β-oxide there is 1 g.-atom of replaceable hydrogen.

The total amount of replaceable hydrogen ions was also estimated by a different method. To a large volume of saturated barium chloride solution in contact with stannic oxide barium hydroxide solution was added in small quantities at a time, each addition being followed by a vigorous shaking. Here also, with both the α- and the β-oxide, the p_H of the solution was found to increase regularly with increasing amounts of alkali added. The addition of alkali was continued until the p_H of the barium chloride solution had risen to about 6·7. By this method it is found that every 6·3 g.-mols. of the β-oxide contain 1 g.-ion of replaceable hydrogen, which agrees fairly closely with the value obtained by the [illegible] method.

In the case of the α-oxide, it is found that for every 4·9 g.-mols. of SnO_2 there is 1 g.-ion of replaceable hydrogen. This shows that for every molecule of SnO_2 the α-oxide contains more replaceable hydrogen ions than the β-oxide. In both cases, however, the stoicheiometric ratio SnO_2 : H is fractional. Further, the increase in p_H observed with repeated washing by barium chloride solution or with successive additions of small quantities of alkali cannot be satisfactorily explained from the chemical point of view of insoluble salt formation. This has been discussed in detail in the previous paper (*loc. cit.*).

Electrical Adsorbability of the Kations and their Capacity to liberate Hydrogen Ions.—20 G. of the β-oxide were shaken with 200 c.c. of the electrolyte solution as before. After 24 hours the clear supernatant solution was withdrawn, and its p_H measured by the *E.M.F.* method. In this way the concentration of hydrogen ions liberated by different salts at the same gram-molecular concentration was determined. The electrical charge of the substance was measured by the electro-endosmotic method. The arrangement used is an improvement of that previously described by the author (*loc. cit.*). The electro-endosmotic flow of a liquid through a porous diaphragm depends, among other factors, directly on the potential across the latter. In the present arrangement a definite potential as indicated by a voltmeter was applied between the electrodes, and could be maintained constant within $\pm$ 1 volt by means of an adjustable resistance. The potential across the diaphragm was determined in the following way. The total resistance, consisting of that of the diaphragm and the electrolyte, was measured by the conductivity method. The electrodes were then lowered so as just to touch the ends of the diaphragm and the resistance was measured again. If T and D be the total and the diaphragm resistances, respectively, then the potential across the diaphragm is given by the expression DV/T, where V is the potential indicated by the voltmeter when the electrodes were in their original position (*i.e.*, when the resistance between them was T). In order that the potential across the diaphragm should remain constant during the electro-endosmotic experiment it is necessary that D/T should remain constant: the maximum variation in this ratio before and after the experiment was always within 3%, and the mean was used in calculating the potential. The value of D/T was, however, found to increase with increasing concentration of the electrolytes, even when the other factors, such as the length of the diaphragm or the distance between the electrodes, were constant; for the same concentration of different electrolytes, however, it was almost the same, as seen from the following results:

Concentration of electrolyte.	Values of D/T for KCl.	LiCl.	NaCl.
0·0002*N*	0·53	0·54	0·53
0·001	0·55	0·55	0·54
0·002	0·56	0·57	0·56
0·004	0·57	0·57	0·56

This increase in the ratio of D/T is probably to be attributed to the relatively high value of the surface conduction in the capillaries, especially when the concentration of the electrolyte inside them is very low (compare Smoluchowski, *Physikal. Z.*, 1905, **6**, 529; Freundlich, " Kapillarchemie," 2nd edtn., p. 249).

Owing to this surface conduction the resistance of the diaphragm does not diminish proportionately as the electrolyte concentration increases. The total resistance T, on the other hand, is determined mainly by that of the electrolyte, and hence it diminishes almost in proportion to the increase in the electrolyte concentration. The consequence is that the ratio D/T increases with the increasing concentration of the electrolyte. The variation of D/T brings about a corresponding change in the value of the potential across the diaphragm. It is therefore evident that a strict comparison of the results at different concentrations of the electrolytes is only possible when the necessary correction due to this variation has been introduced. In Table I the distance moved by the air bubble corresponds to a potential of 100 volts across the diaphragm. The plus and the minus signs indicate the charge of the diaphragm.

TABLE I.

β-Stannic oxide (water content, 55%).

0·002	3·78	3·81	3·82	—	—	—

Concentration of electrolyte (g.-mols.).	Distance moved by the air bubble (cm. in 2 mins.). $MgCl_2$.	$BaCl_2$.	$SrCl_2$.	LiCl.	NaCl.	KCl.
0·0	−0·43	−0·43	−0·43	−0·43	−0·44	−0·44
0·0003	+0·70	+0·35	+0·30	−1·03	−1·20	−1·35
0·001	+1·20	+1·0	+0·90	−0·82	−0·93	−1·0
0·002	+1·30	+1·1	+1·0	−0·48	−0·54	−0·6
0·004	+1·37	+1·35	+1·1	−0·32	−0·30	−0·3
0·008	+1·40	+1·35	—	−0·16	−0·22	−0·2

It will be seen from the above data that the capacity of the kations to liberate hydrogen ions is in the order $Mg^{\cdot\cdot} > Ba^{\cdot\cdot} > Sr^{\cdot\cdot} > Li^{\cdot} > Na^{\cdot} > K^{\cdot}$. The electro-endosmotic experiments show that hydrated stannic oxide is charged negatively in contact with water, and that the capacity of the kations to diminish the negative charge of the surface, as indicated by the movement of the air bubble, is in the same order. In the case of the alkali-metal chlorides at low concentrations the negative charge of the surface is greater than with pure water. The bivalent kations reverse the negative charge of the surface at as low a concentration as 0·0003*M*. The concentration of the liberated hydrogen ions, however, increases continuously up to a concentration of 1*M* of the bivalent kations. This shows that hydrogen ions continue to be liberated even after the surface has become positively charged.

The Adsorption Theory and the Liberation of Hydrogen Ions by Kations.—As stannic oxide is negatively charged, it follows from Mukherjee's theory (*loc. cit.*) that the hydrogen ions are held in the neighbourhood of the surface by electrostatic attraction. Hence, the greater the capacity of a kation to diminish the negative charge the greater should be its effect on the liberation of hydrogen ions, and that is what has been observed. The observed reversal of electrical charge of stannic oxide by bivalent kations, and the change in p_H on repeated washing with barium chloride solution can be explained in exactly the same way as before (Ghosh, *loc. cit.*, p. 2611). The rise in p_H with successive additions of alkali also admits of a simple explanation. The addition of alkali in small amounts simply removes the liberated hydrogen ions, and therefore produces the same effect as that of withdrawing the original acidic barium chloride solution and replacing it by a fresh one of p_H 6·6. That the α-oxide contains more replaceable hydrogen ions, mol. for mol., than the β-oxide, only shows that the former consists of finer particles and hence possesses greater active surface than the latter.

The Adsorption of Anions.

Reference to the electro-endosmotic data shows that at low concentrations of the chlorides of the univalent kations the negative charge of hydrated stannic oxide increases. This may be due either (1) to the primary adsorption of the anion, or (2) to a redistribution of the kations in the " double layer " leading to an increase in the number of " uncovered " primarily adsorbed anions (which in this case may be the SnO_3H' ion) (compare Mukherjee and Iyer, *J. Indian Chem. Soc.*, 1926, **3**, 321). Among the kations, potassium has been found to be least effective in diminishing the negative charge of the surface. A measurement of adsorption of

potassium salts may therefore give some idea of the adsorption of anions, since any adsorption of the salt can in this case be attributed to this cause. For this purpose 10 g. of the substance were shaken in a Pyrex-glass bottle with 100 c.c. of a solution of potassium salt, and after 24 hours the solution was analysed. The results given below (for β-oxide of 54·4% water content) show that there is hardly any primary adsorption of anions:

Adsorption of Acids and its Relation to Electrical Charge.

A weighed quantity of hydrated stannic oxide was shaken as before (p. 3029) with a measured volume of an acid solution of known strength, and after 24 hours the acid concentration in the supernatant liquid was determined, the *E.M.F.* method being used for low concentrations, and alkali titration for others. As the hydrated oxide contained a large amount of water, a correction had to be introduced for its diluting effect. The amount of adsorption was calculated by multiplying the difference between the corrected initial concentration of the acid and its concentration after adsorption by the total volume of the solution. Tin was not present in the acid solutions within the range of concentrations investigated; the observed adsorption was therefore not due to the formation of any soluble tin salt. The electrical charge was measured by the electro-endosmotic method as previously described. The sample used in Table II is different from that used in the other table. In the following tables α denotes the number of g.-ions of hydrogen adsorbed, and d the distance (in mm.) moved by the air bubble in 2 minutes. In each case 200 c.c. of acid solution were used, together with 20 g. of β-oxide of 54·5% water content.

The electro-endosmotic results show that all the acids, except phosphoric, reverse the initial negative charge of the surface. This indicates that hydrogen ions are primarily adsorbed by the surface. In the case of sulphuric acid, it will be noticed that with increasing concentration the positive charge at first increases, reaches a maximum, and then diminishes again, whereas for

are enclosed in parentheses in each case were used in calculating the corresponding values of the constants.

acid it continues to increase within the range investigated. The ratio of the total change in electrical charge (as indicated by the movement of the air bubble) to the amount of hydrogen ions adsorbed, however, diminishes continuously from the start, showing that with increasing concentration of the acids the electrical adsorption of the anions is preponderating more and more over the primary adsorption of the hydrogen ions. In the above table the calculated values of a were obtained from the expression $K_0C/(1 + K_1C)$ (compare Langmuir), where K_0 and K_1 are constants. It can be easily shown that K_0/K_1 is a measure of the active surface.

The agreement between the observed and calculated values is fair. A comparison of the adsorption of the acids with their effect on the electrical charge shows that the adsorption is greater the less the positive charge of the surface. The order of adsorption of the acids is $H_3PO_4 > H_2SO_4 > HCl > HNO_3, CCl_3{\cdot}CO_2H, C_6H_5{\cdot}SO_3H$. The magnitude of adsorption of the monobasic acids is very nearly the same, that of hydrochloric acid, however, being slightly the greatest. The capacity of the different acids to increase the positive charge of the surface is in the order HNO_3, etc. $> HCl > H_2SO_4 > H_3PO_4$. The above results therefore lead to the conclusion that there exists a sort of inverse proportionality between the adsorption of acids and their effect on the positive charge of the surface. This is to be expected also on theoretical grounds: the other factors remaining constant, the chance of a hydrogen ion reaching the surface is the less the greater the positive charge of the surface, owing to increasing electrostatic repulsion.

(1) When an acid with a multivalent anion is used, the anion because of its high electrical adsorbability diminishes the positive charge of the surface, and hence favours the further primary adsorp-

tion of hydrogen ions; moreover, multivalent anions may bring about increase in adsorption of hydrogen ions in another way. (2) When a multivalent anion is electrically adsorbed (or bound) opposite to one of the primarily adsorbed hydrogen ions, all its valencies except one are free, and hence a number of hydrogen ions corresponding to the number of the free valencies of the anion will be drawn near the surface. This will produce the same effect as an increase in the number of primarily adsorbed hydrogen ions. (3) There is yet another factor which may influence the adsorption of hydrogen ions. If the surface be positively charged, there will be an equivalent number of anions surrounding it. Some of these will be free and their number will increase with increasing electrical charge. If these free ions exist in the form of a diffuse layer of thickness, say, δ round the surface, then within this layer the average concentration of hydrogen ions will be much less than in the bulk of the solution. If the electrical charge is reduced to zero or brought to a very low value by increasing the anion concentration, then the value of δ becomes negligibly small and hence a volume of liquid $S\delta$ (where S is the total solid–liquid interfacial area) which was formerly only partly accessible to the hydrogen ions now becomes completely so. This will also produce an apparent increase in the adsorption of hydrogen ions.

Effect of Neutral Salts on the Adsorption of Hydrogen Ions.

The effect of electrical charge on the adsorption of acids can also be tested in the following way. If the concentration of the hydrogen ions be maintained constant and that of the anion is increased by adding a neutral salt with an inactive kation, the positive charge of the surface will be diminished, and hence the adsorption of hydrogen ions will be greater in presence of a neutral salt than in its absence. It will be seen from the previous experiments that of all the kations the potassium ion is the least active; potassium salts were therefore used in the following experiments. The adsorption of acid was measured as previously described.

It will be observed that the adsorption of nitric acid is considerably greater in presence of potassium nitrate than in its absence. When the concentration of the salt is kept constant and that of the acid varied, the percentage rise in adsorption increases with the decreasing concentration of the acid. Again, keeping the concentration of nitric acid constant and increasing that of the salt, the adsorption of the acid is found to increase. Here we are not dealing with any multivalent anion, and hence increase in adsorption is to be attributed to the diminution of the positive charge of the surface and also of the thickness of the diffuse layer δ.

TABLE IV.

0·0481	0·2	0·0158	17·0
0·0491	0·05	0·0156	17·6

The adsorption of hydrogen ions is much greater in the nitric acid–potassium sulphate mixture than in nitric acid and potassium nitrate. In this case, in addition to the two factors mentioned above, the effect of the multivalent anions makes itself felt. In the sulphuric acid–potassium sulphate mixture the adsorption of acid is not at all increased: on the contrary, a slight decrease in adsorption is observed. This is not surprising, for in presence of 0·015N-sulphuric acid the charge of the surface is very small (nearly zero), and hence an increase in the number of SO_4'' ions is not likely to favour any further adsorption. The $K^{\cdot}$ ions on the other hand can displace from the mobile layer some of the hydrogen ions associated with the electrically adsorbed SO_4'' ions, and thus slightly decrease the adsorption.

The Variation of Active Surface with the Amount of Substance taken.—It has been emphasised that in the interaction of stannic oxide with electrolytes it is the solid–liquid interface that is directly taking part in the reaction. The question arises as to how the active surface increases with the amount of substance taken. It has already been mentioned that K_0/K_1 is a measure of the active surface. Therefore, by taking different quantities of stannic oxide and determining the values of K_0 and K_1 for each quantity, it is possible to find how the active surface varies with the amount of substance. The adsorption of acid was measured as before. [illegible] c.c.

of a sulphuric acid solution were used, with 10 g. of the β-oxide (water content, 54·5%) in the first case and 5 g. in the second.

	Initial conc. (corr.).	Final conc.	$a \times 10^3$.	K_0.	K_1.	K_0/K_1.
(1)	0·071	0·0328	4·0	1·03	228	0·0045
	0·0475	0·0146	3·46			
(2)	0·073	0·052	2·14	0·44	186	0·0024
	0·049	0·0295	1·99			

It will thus be seen that the active surface increases in the ratio 1 : 1·9 as the amount of substance is doubled.

Summary.

1. A study of the interaction of hydrated stannic oxides with electrolytes shows that the adsorption theory offers a much better explanation of the observed facts than the chemical theory of insoluble salt formation.

2. In accordance with Mecklenburg's views, the α-oxide has been found to possess greater active surface per unit weight, and hence finer particles, than the β-oxide.

3. The capacity of the kations to liberate hydrogen ions is in the order $Mg^{\cdot\cdot} > Ba^{\cdot\cdot} > Sr^{\cdot\cdot} > Li^{\cdot} > Na^{\cdot} > K^{\cdot}$, and, in satisfactory agreement with Mukherjee's theory, the same order has been observed in their effect on the negative charge of the surface.

4. The electro-endosmotic results indicate that the hydrogen ions are primarily adsorbed, and the adsorption of an acid is greater the less the positive charge of the surface. The order of adsorption of the acids is $H_3PO_4 > H_2SO_4 > HCl > HNO_3, C_6H_5{\cdot}SO_3H, CCl_3{\cdot}CO_2H$. The capacity of the acids to increase the positive charge of the surface is in the order HNO_3, etc. $> HCl > H_2SO_4 > H_3PO_4$. This leads to the conclusion that the greater the capacity of the anion to diminish the positive charge of the surface the greater is the adsorption of the hydrogen ions. The adsorptions of the kations and anions are thus not independent of each other.

5. In presence of salts with inactive kations, the adsorption of hydrogen ions is increased. In this respect, salts with multivalent anions are more effective than those with univalent anions.

6. The active surface has been found to vary nearly proportionately with the amount of substance.

In conclusion, I take this opportunity of expressing my most sincere thanks to Professor F. G. Donnan, C.B.E., F.R.S., for his advice and encouragement.

CCCXCVIII.—*The Effect of the Spatial Position of Substituent Groups on Acidic Strength.*

By BERNHARD FLÜRSCHEIM.

SOME years ago (J., 1909, **95**, 718; 1910, **97**, 84), I attempted to show that the electrolytic equilibria of acids, bases, and salts depend on the same three internal (constitutional) factors p, q, and s which determine reactions in general. In so far as the steric factor (s) is concerned, I suggested that the rate of association of ions is retarded by spatial obstruction, whereas the reverse process of dissociation into ions remains unaffected, so that *ceteris paribus* steric hindrance must raise the dissociation constant. In support of this view, the relative steric effects on dissociation constants were shown to run parallel to the relative steric inhibitions of other reactions; the order for different substituents and positions being:

$$I > Br,C_6H_5 > Cl,O,N,C(CH_3,CO) > H;$$

o- > β- > α-; and γ-, δ-, m-, p-, side-chain in o- almost = 0. The evidence included a correlation of the dissociation constants of more than 100 acids and bases and of the dissociation constants and relative hydrolysis of certain organic salts by means of semi-quantitative evaluations of the steric and the other two effects. Later (*Trans. Faraday Soc.*, 1923, **19**, 531; *Phil. Mag.*, 1924, **47**, 569) I suggested that the remarkable extent to which the approach even of a hydrogen ion can be inhibited sterically by substituents in the anion is intelligible in view of Lapworth's proof that hydrogen ions are solvated.

Independent evidence for the steric effect in electrolytic equilibria was found by me (*Chem. and Ind.*, 1925, **44**, 249) in the dissociation constants of certain ethylenic isomerides. Since the ratio of these constants for α-bromo*allo*cinnamic acid/α-bromocinnamic acid = maleic acid/fumaric acid = 15 (approx.), and *iso*crotonic acid/crotonic acid > 1, and since p and q must be identical for the *cis*- and the *trans*-form of the same acid, the conclusion was drawn that the greater strength of each *cis*-form must be due to a pure steric effect in the above sense; if it were a *polar* effect across space, the ratio K_{cis}/K_{trans} would be smaller for the α-bromocinnamic acids (effect of phenyl) than for maleic and fumaric acids (effect of carboxyl), and would be less than 1 for the crotonic acids (effect of methyl).

A recent paper by D. H. Hey (this vol., p. 2321) deals wholly with this question of the steric effects on acidic strength. This author has evidently overlooked the papers mentioned above, although he puts forward views on this question identical with those put forward by me, and his arguments are the same as those used by me, no reference is made to my work.

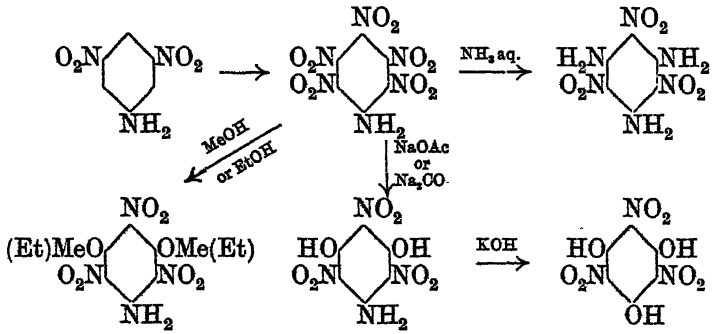
Contrary to the general assumption that ionic reactions are instantaneous, the introduction of a steric delay in association implied, of course, that association of ions is a time reaction, from which it follows that dissociation must also be a time reaction (governed, I suggest, by the internal factors p and q); if dissociation alone were instantaneous, it would always be practically complete. The principle of ionic time reactions has recently also been advocated by Brönsted and Pedersen (*Z. physikal. Chem.*, 1924, **108**, 230) and Brönsted (*Ber.*, 1928, **61**, 2050, footnote), who suggest that it is therefore "possible, but not very probable, that the same equilibrium (strength) might be determined by very different values of the absolute velocities of dissociation and association." The introduction of a steric factor, however, for association alone transforms such a remote contingency into a virtual certainty. Thus *o*-chloro- and *o*-iodo-benzoic acid have approximately the same dissociation constant; let k_1 and k_2, respectively, be the rates of dissociation and association in the chloro-acid, and $m \times k_1$ and $n \times k_2$ those in the iodo-acid, then we have (compare J., 1909, **95**, 731) $m < 1$ (since p for I $<$ Cl) and $n < 1$ (since s for I $>$ Cl); whenever $m = n$, the dissociation constants of the two acids are, of course, identical ($= k_1/k_2$), and this is what approximately applies in the present case.

Spiers and Thorpe (J., 1925, **127**, 538) introduced an "approach effect" brought about by altered valency direction. Where primary dissociation constants are concerned, this approach effect is obviously a special case of the steric effect postulated by me, for which these authors' observations supply further valuable evidence. In cases of secondary dissociation, however, the electrostatic effect of the first charge on the charges involved in the secondary dissociation (Ostwald, *Z. physikal. Chem.*, 1892, **9**, 558; Bjerrum, *ibid.*, 1925, **106**, 219) may, and usually will, outweigh all other factors (*e.g.*, in the classical example, secondary dissociation constant of maleic acid $<$ fumaric acid). In view of what has been said above, Spiers and Thorpe's remark on my views—"no explanation is offered as to how this steric influence is produced"—can hardly be upheld.*

* Quite recently (*Ber.*, 1928, **61**, 1524), the possibility of a steric inhibition of the association of ions has also been admitted by Hückel; and since the above was written, the steric effect on the tautomerism of kations (or "anionotropy" or "mobile anion tautomerism," to use recently coined expressions), *e.g.*, in the triphenylmethane, benzopyrilium, and acridinium series (Flürscheim, J., 1910, **97**, 90—94), has found support in an investigation by Cook (this vol., p. 2798) on a similar katonic tautomerism in the anthracene series.

FLEET, HAMPSHIRE. [*Received, October 8th*, 1928.]

CCCXCIX.—*Pentanitroaniline.*



By BERNHARD FLÜRSCHEIM and ERIC LEIGHTON HOLMES.

PRELIMINARY experiments had indicated (Flürscheim and Simon, P., 1910, **26**, 81) that when 3 : 5-dinitroaniline is nitrated in mixed acid, " a nitroamine is first formed, which is subsequently converted into a compound which may be pentanitroaniline." At that time, this " compound " had only been obtained in a very impure condition and in very poor yield, so that its nature could not be definitely ascertained. The investigation of this reaction has now again been taken up.

3 : 5-Dinitroaniline and *m*-nitroaniline behave quite differently towards mixed acid. In both cases, nitroamides are primarily formed, but whereas with *m*-nitroaniline these remain in solution (provided that the acid is sufficiently concentrated), so that the first and only product which separates is pure 2 : 3 : 4 : 6-tetranitroaniline, 3 : 5-dinitroaniline gives rise to sparingly soluble nitroamides. Their rearrangement to the corresponding nuclear nitro-derivatives is retarded by their low solubility, and before it can be completed, they decompose—unless special precautions are taken—with violent flashes. When, however, such decomposition is prevented, the colour gradually changes from orange-red to deep yellow, corresponding to a transition of the nitroamides into nearly pure pentanitroaniline. The latter can be obtained quite pure by recrystallisation from benzene; one molecule of benzene is retained at first, but can be easily removed.

In most respects, the chemical and physical properties of pentanitroaniline are similar to those of tetranitroaniline. For instance, both compounds are golden-yellow; both melt with decomposition near 200° (the latter at 216—217°, the former at 192°; heating at the rate of 5° per minute). Both, when dropped into a red-hot crucible, a few centigrams at a time, flash without detonation and with the formation of mere traces of carbon. In both, the nitro-groups in the meta-positions (one in tetranitroaniline, two in pentanitroaniline) are readily replaced, and the amino-group less readily, by the same reagents, corresponding derivatives being formed in either case. In this way, just as numerous penta-substituted derivatives of benzene had become easily accessible by means of tetranitroaniline, many completely substituted benzene derivatives have become available *via* pentanitroaniline.

reactions have been carried out represented by the following formulæ:

These transformations prove that all five nitro-groups are in the nucleus—as was to be expected, since pentanitroaniline has not the properties of a nitroamide.

In two directions only has pentanitroaniline been found to differ essentially from tetranitroaniline: its greater solubility in organic solvents, and its behaviour on acetylation. The table of approximate solubilities given below for 2 : 4 : 6-trinitroaniline, tetranitroaniline and pentanitroaniline reveals marked differences and, it seems, no connexion between the number of nitro-groups and the solubility in a given solvent. On acetylation by means of acetic anhydride with a little concentrated sulphuric acid, tetranitroaniline yields its acetyl derivative, but from pentanitroaniline an acetyl derivative is produced in which at least one nitro-group has been replaced. Preliminary tests appear to indicate that this compound does not belong to the series obtained by the removal of *m*-nitro-groups, so that the possibility that acidic reagents may replace a *p*-nitro-group must be examined; it should be remembered that in pentanitroaniline even the *p*-nitro-group has two other nitro-groups adjacent to it.

The work is being continued.

Experimental.

Pentanitroaniline.—1 Part of 3 : 5-dinitroaniline, prepared by Flürscheim's modification of Bader's method (*J. pr. Chem.*, 1905, **71**, 537), is dissolved in 20 parts (by volume) of oleum (5% SO_3), and 1·5 parts (by volume) of nitric acid (*d* 1·52) are added below 20°. The solution is then heated at 70—75° for 3 hours *without shaking or stirring*. In this way the nitroamides remain suspended in a finely divided state, whereas shaking or stirring causes them to cake together, whereupon they usually decompose with a vivid flash.

The spent acid is removed by suction, and the product (nearly pure pentanitroaniline, decomp. 189°) recrystallised from benzene. Up to 3 g. of 3 : 5-dinitroaniline have, so far, been nitrated at a time,* giving an average yield of 1·5 g. of pure pentanitroaniline (containing 1 mol. of benzene) per 3 g. of 3 : 5-dinitroaniline used. Pentanitroaniline crystallises with 1 mol. of benzene in golden-yellow prisms. Dr. I. Knaggs, of the Davy Faraday Laboratory, who very kindly examined these microscopically, informs us that they are either monoclinic or triclinic, a decision between these alternatives not being feasible without detailed measurements. The ground material, when brought to constant weight by 18 hours' exposure in a vacuum at room temperature, lost 19·6% in weight ($C_6H_2O_{10}N_6,C_6H_6$ requires C_6H_6, 19·7%). The crystals remain unaffected in shape and colour by the loss of benzene, but become opaque. Benzene-free *pentanitroaniline* melts at 192° with rapid decomposition, after darkening to a deep orange at 160—170° (rate of heating 5° per minute) (Found: C, 22·7; H, 0·65; N, 26·45, 26·4. $C_6H_2O_{10}N_6$ requires C, 22·6; H, 0·6; N, 26·4%). Approximate comparative solubilities are given in the following table:

	2 : 4 : 6-Trinitroaniline.	Tetranitroaniline.	Pentanitroaniline.
Benzene.	0·025 g. in 0·5—1·0 c.c. at 74·5°. Cryst.	0·02 g. in 5—6 c.c. at 74·5°. Cryst.	0·023 g. in less than 0·5 c.c. at 74·5°. Cryst.
Acetic acid.	0·019 g. in 0·25—0·5 c.c. at 75°. Cryst.	0·025 g. in 0·95—1·2 c.c. at 75°. Cryst.	0·019 g. in less than 0·2 c.c. at 20°. No cryst.
Acetone.	0·030 g. in 0·25—0·4 c.c. at 50°. Cryst.	0·021 g. in 0·25—0·4 c.c. at 50°. No cryst.	0·024 g. in less than 0·1 c.c. at 20°. No cryst.
H_2SO_4 (100%).	0·021 g. in less than 0·3 c.c. at 20°. No cryst.	0·020 g. in 4·5—5·0 c.c. at 75°. Cryst.	0·023 g. in 11·5—13·5 c.c. at 75°. No cryst.

"Cryst." or "no cryst." indicates whether or no the nitro-compound crystallises on cooling in running water. The lower values, for c.c. used, indicate a deficiency, the higher values an excess, of solvent required for complete solution.

From 3 : 5-dinitroacetanilide a lower yield of pentanitroaniline was obtained than from dinitroaniline itself: 4·5 g. of the acetyl derivative, nitrated in 80 c.c. of sulphuric acid monohydrate with 6·0 c.c. of nitric acid (*d* 1·52) for 6 hours at 65—70°, gave only 0·6 g.

* An improved method of nitrating 3 : 5-dinitroaniline which we have since found (in which 1 part of this amine in 40 parts by vol. of 100% sulphuric acid and 2·5 parts by vol. of nitric acid, *d* 1·52, is heated to 75° during ½ hour and kept at 75° for 1 hour) avoids the separation of nitroamides altogether and thereby makes it possible to nitrate any desired amount at a time. It gives the improved yield of 0·62 part of pentanitroaniline, immediately pure as it separates from the acid.

of pentanitroaniline; and 12·3 g., nitrated with the same proportic of oleum (5% SO_3) and nitric acid as were used for the amine, ga in 5 hours at 65—70° only 1·5 g. of pentanitroaniline.

2 : 4 : 6-*Trinitro*-5-*aminoresorcinol*.—To a solution of 0·50 g. benzene-free pentanitroaniline in 5 c.c. of acetone, an excess aqueous sodium acetate was added gradually with good shaki The solution, which turned red with some effervescence, v frequently shaken during ½ hour, the acetone driven off, and excess of concentrated hydrochloric acid added to the residue. T yellow precipitate obtained (m. p. 220°, decomp.) crystallised fr benzene–alcohol in small deep yellow crystals, m. p. 236—2: (decomp.) (heating, 5° per minute). This *compound* was obtair in brownish-yellow, fine needles of the same m. p. and mixed m. when 1 g. of pentanitroaniline was heated on a water-bath w 10 c.c. of saturated sodium carbonate solution, with subsequ dilution with water, until the separated sodium salt had redissolv and precipitation with hydrochloric acid. Yield, 0·609 g. of cr material (decomp. 230°), which was recrystallised from wa (Found: N, 21·8. $C_6H_4O_8N_4$ requires N, 21·5%).

2 : 4 : 6-*Trinitrophloroglucinol*.—1 G. of benzene-free pentanit aniline in 10 c.c. of a saturated sodium carbonate solution a 10 c.c. of water was heated until it dissolved, 10 c.c. of 10% aque potassium hydroxide were then added, and heating was contin on a water-bath until the evolution of ammonia had ceased. Wa was added, to redissolve the separated potassium salt, followed an excess of hydrochloric acid. After evaporation in a vacuum o sulphuric acid, the compound was extracted with ether (yie 0·562 g.). Trinitrophloroglucinol is very soluble in hot water a appreciably soluble in cold water, but it can easily be recrystallis from water by adding a very little hydrochloric acid, whereby t solubility is much reduced. It was thus obtained in characterist long, spear-like crystals with an ochre colour, m. p. 167° (in agr ment with Jackson and Warren, *Amer. Chem. J.*, 1893, **15**, 615) af prior heating to remove water of crystallisation (Found: N, 16 Calc.: N, 16·1%).

2 : 4 : 6-*Trinitro*-5-*aminoresorcinol Dimethyl Ether*.—Benzene-f pentanitroaniline (2·8 g.) was refluxed for 6 hours with 28 c.c. of d methyl alcohol and then cooled. A little bicarbonate solution w added to transform traces of free hydroxy-compounds into th salts, and the *ether* was then precipitated by an excess of wa (yield, 1·76 g.; m. p. 125°). After recrystallisation from eth acetate–ligroin it had m. p. 127—127·5°, and after further recryst lisation from benzene lemon-yellow needles, m. p. 127·5°, we obtained (Found: C, 33·1; H, 2·8; N, 19·7. $C_8H_8O_8N_4$ requir

C, 33·3; H, 2·8; N, 19·4%). A small quantity of a mixture of bicarbonate-soluble hydroxy-compounds was isolated. These must be produced by the action of traces of water during the replacement of the nitro-groups, since the ether, once formed, is not attacked even by boiling aqueous methyl alcohol; from 0·5 g. of the ether, after 2 hours' boiling with 95% methyl alcohol, 0·496 g. was recovered unchanged.

2 : 4 : 6-*Trinitro-5-aminoresorcinol Diethyl Ether*.—This was prepared in a similar manner from 2 g. of benzene-free pentanitroaniline and 20 c.c. of dry ethyl alcohol (yield, 1·176 g.; m. p. 123°). After solution in alcohol, and retreatment with bicarbonate and water as above, the *ether* had m. p. 125—126°, which became constant at 127·25—127·75° after successive recrystallisations from alcohol and petrol. The product crystallised in yellow blades (Found: C, 38·0: H, 3·9; N, 17·95, 18·1. $C_{10}H_{12}O_8N_4$ requires C, 38·0; H, 3·8; N, 17·7%). The dimethyl and diethyl ethers have the same melting point; a mixture of the two, however, melts at a lower temperature.

2 : 4 : 6-*Trinitro*-1 : 3 : 5-*triaminobenzene*.*—1·000 G. of benzene-free pentanitroaniline was gradually added to 18 c.c. of 10% aqueous ammonia. The material instantly became red, then light brown on shaking. After boiling, an orange-yellow powder (0·670 g.) was obtained corresponding to the description of trinitro-1 : 3 : 5-triaminobenzene given by Jackson and Wing (*Amer. Chem. J.*, 1888, **10**, 282), being insoluble in nearly all solvents, but recrystallisable from aniline, and showing no signs of melting up to 300° (Found: N, 32·6. $C_6H_6O_6N_6$ requires N, 32·6%). The symmetrical constitution of this compound, involving the adjacency of two nitro-groups to each amino-group, is confirmed by the fact that 0·030 g., dissolved in 1·84 g. of concentrated sulphuric acid, is precipitated by 0·15 g. of water.

Acetylation of Pentanitroaniline.—Pentanitroaniline (0·42 g.) did not react with 5 c.c. of acetic anhydride and two drops of concentrated sulphuric acid on heating on a water-bath for 15 minutes, the cooled solution being subsequently poured on ice. When, however, 0·5 g. of benzene-free pentanitroaniline was *boiled* with 5 c.c. of acetic anhydride and two drops of concentrated sulphuric acid, either for 5 minutes, or better for only a few seconds, followed by immediate water-cooling, the excess of acetic anhydride then being

* Addendum.—We have since succeeded in reducing this compound to hexa-aminobenzene, a crystalline compound, readily soluble in water, which melts and decomposes at about 255° (rate of heating, 30° per min.), slowly darkens in the air, gives a hexa-acetyl derivative (not melted at 300°), a tripicrate, and is characterised by the precipitation of a tetrahydro[illegible] when 0·2 g. of the base in 3 c.c. of water is added to 10 c.c. of co[illegible] hydrochloric acid.

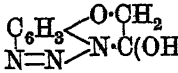
mostly removed in a vacuum and the residue mixed with snow, a solid was obtained which crystallised from benzene or from petrol (b. p. 100—120°) in almost colourless, short, sword-shaped crystals of constant m. p. 147—147·5°. Yield (in the case of only brief boiling), 0·25 g. (Found: N, 18·9. A tetranitrodiacetamidophenol, $C_{10}H_7O_{11}N_5$, requires N, 18·8%). The nitrogen content of this compound makes it certain that at least one nitro-group has been replaced, but preliminary tests with the small amount available on its behaviour toward sodium acetate and ammonia render it probable that the replaced nitro-group did *not* occupy one of the meta-positions.

Acetylation of Tetranitroaniline.—When tetranitroaniline was treated similarly, *viz.*, 0·8 g. boiled for 5 minutes with 8 c.c. of acetic anhydride and three drops of concentrated sulphuric acid, most of the acetic anhydride removed in a vacuum, and snow added, 0·76 g. of crude tetranitroacetanilide, m. p. 163—164° (decomp.) (heating at the rate of 5° per minute), was obtained. This compound, which has been mentioned (P., *loc. cit.*) but not described, forms, on recrystallisation from benzene–glacial acetic acid, slightly yellow, small needles, decomp. 169° (constant) (Found: N, 22·4. $C_8H_5O_9N_5$ requires N, 22·2%). Acetylation in this case, therefore, is not attended by the removal of a nitro-group.

We desire to record our obligation to the Advisory Council of the Department of Scientific and Industrial Research for a grant to one of us (E. L. H.); also to Sir W. H. Bragg and the Royal Institution, who have enabled us to utilise the excellent facilities of the Davy Faraday Laboratory, where this work was carried out.

[*Received, October 8th,* 1928.]

CCCC.—*The Synthesis of Four Amino-3-hydroxy-1 : 4-benziso oxazines.*



By GEORGE NEWBERY and MONTAGUE ALEXANDRA PHILLIPS.

OF the four possible amino-3-hydroxy-1 : 4-benz*iso*oxazines in which the amino-group is in the benzene ring, only the 6-amino-derivative has hitherto been described (Howard, *Ber.*, 1897, **30**, 2103). As the characterisation of these isomerides was necessary for the orientation of certain of their arsinic acid derivatives, their synthesis from the corresponding nitro-2-aminophenols is here described.

6-Amino-3-hydroxy-1 : 4-benz*iso*oxazine obtained from 4-nitro-2-aminophenol by chloroacetylation, followed by ring closure by

means of alkali and subsequent reduction, melted at 255°, whereas Howard (*loc. cit.*) gives 225°. The same product, m. p. 255°, was also obtained by the reduction of 2 : 4-dinitrophenoxyacetic acid.

The nitration of 4-acetamidophenoxyacetic acid, followed by hydrolysis, and the nitration of 4-aminophenoxyacetic acid by Howard's method gave the same nitro-4-aminophenoxyacetic acid. On reduction, 6-amino-3-hydroxy-1 : 4-benz*iso*oxazine, m. p. 255°, was obtained.

The basicity of 5-*amino*-3-*hydroxy*-1 : 4-*benz*isoo*xazine* is of a lower order than that of its isomerides; *e.g.*, 1½ mols. of *N*/10-mineral acid are required for its solution, whereas the others dissolve in 1 mol. of *N*/10-acid to give salts which are neutral to Congo-red. The other isomerides diazotise normally, but the 5-isomeride forms with nitrous acid a *triazole* which crystallises with a molecule of water; this cannot be driven off at 120° and the triazole may therefore have the constitution  .

EXPERIMENTAL.

(A) 5-*Amino*-3-*hydroxy*-1 : 4-*benz*isoo*xazine*.—3-Nitro-2-aminophenol, obtained by Fourneau (*Bull. Soc. chim.*, 1927, **41**, 499) by the de-arsenication of 3-nitrobenzoxazolone-5-arsinic acid and by King (J., 1927, 1059) in small yield by nitration in acetic anhydride of *ON*-diacetyl-*o*-aminophenol (Ingold and Ingold, J., 1926, 1321), was obtained in improved yield by treating the crude nitration product as follows:

45 G. were boiled under reflux with hydrochloric acid (150 c.c.; *d* 1·16) for 45 minutes; 190 c.c. of 10*N*-sodium hydroxide were added to the cooled solution, which, still acid to Congo-red, was then boiled with charcoal and filtered. On cooling, 3-nitro-2-aminophenol (17 g., m. p. 217°) separated. The addition of a further 25 c.c. of 10*N*-sodium hydroxide gave a mixture (4·7 g., m. p. 180—185°). By rendering the liquor, which was still acid to Congo-red, neutral to litmus, 5-nitro-2-aminophenol (5·6 g., m. p. 200°) was obtained (total yield of nitro-2-aminophenols, 94%). The mixture of m. p. 180—185°, on similar fractional neutralisation of its solution in acid, gave 1·5 g. each of the above nitroaminophenols. The total yields isolated are thus 63·5 and 24·4% of the 3- and 5-nitro-2-aminophenols, respectively, which are considerably at variance with those estimated by Ingold and Ingold (*loc. cit.*).

The mother-liquors on extraction with ether gave a mixture of 5-nitro-2-aminophenol and *o*-aminophenol (m. p. 170°).

3-Nitro-2-aminophenol crystallised, on addition of

sodium acetate to its solution in warm concentrated hydrochloric acid, in red needles changing to hexagonal plates, m. p. 212°. The mono- and di-acetyl derivatives agreed in m. p. with those described by Ingold and Ingold (*loc. cit.*).

3-*Nitro*-2-*chloroacetamidophenol.* To 3-nitro-2-aminophenol (10 g.) in acetone (80 c.c.), chloroacetyl chloride (8 c.c.) was added with shaking (temp. 25°). After 30 minutes, the bulk of the acetone was removed. The *chloroacetyl* derivative, which slowly separated (11·5 g.; 88%), crystallised from alcohol in yellow prisms, m. p. 153—154°, readily soluble in organic solvents but insoluble in water (Found: N, 12·0; Cl, 15·2. $C_8H_7O_4N_2Cl$ requires N, 12·1; Cl, 15·4%).

5-*Nitro*-3-*hydroxy*-1 : 4-*benzisooxazine.* A paste of 3-nitro-2-chloroacetamidophenol (6 g.) and water (5 c.c.) was treated with 2*N*-sodium hydroxide (20 c.c.) and heated in a boiling water-bath for 30 minutes. On acidification, the *product* separated in orange prisms (4·9 g.; 98%), m. p. 115—116°. The solution in boiling water (50 parts) deposited, on cooling, long, prismatic needles of the same m. p. (Found: N, 14·2. $C_8H_6O_4N_2$ requires N, 14·4%).

5-*Amino*-3-*hydroxy*-1 : 4-*benzisooxazine.* A mixture of the above nitro-compound (3 g.) with iron powder (6 g.) was added to boiling water (60 c.c.) containing glacial acetic acid (3 c.c.). After short boiling, the mixture was made faintly alkaline to litmus with 2*N*-sodium hydroxide and boiled with an equal volume of water. The *product* crystallised, on concentration of the filtered solution, in colourless prisms (1·6 g.; 73%), m. p. 236° after recrystallisation. It is moderately easily soluble in alcohol (Found: N, 16·9. $C_8H_8O_2N_2$ requires N, 17·1%). The *hydrochloride* formed characteristic rhombs, hydrolysed by boiling water (Found: N, 14·0; Cl, 17·3, $C_8H_8O_2N_2$,HCl requires N, 13·9; Cl, 17·7%). The *acetyl* derivative (Found: N, 13·3. $C_{10}H_{10}O_3N_2$ requires N, 13·6%) crystallised from alcohol in colourless prisms, m. p. 255°. The *triazole*, made by addition of sodium nitrite (1 mol.) to a suspension of the hydrochloride in cold water, crystallised from boiling water in plates, m. p. 204° (Found: N, 21·7. $C_8H_5O_2N_3$,H_2O requires N, 21·8%).

(B) 6-*Amino*-3-*hydroxy*-1 : 4-*benzisooxazine.*—(a) When a mixture of 2 : 4-dinitrophenoxyacetic acid (Pratezi, *Gazzetta*, 1892, **21**, 402; m. p. 147—148°; 24 g.), iron filings (83 g.), water (100 c.c.), and hydrochloric acid (25 c.c.; *d* 1·16) was warmed, a vigorous reaction set in which was controlled when necessary by cooling. After a further 15 minutes' heating, the liquid was filtered and treated with a large excess of hydrochloric acid. The hydrochloride, together with a further amount obtained by extraction of the

ferric oxide with boiling water, weighed 9·5 g. (47·5% yield) and crystallised in plates, m. p. 300° (decomp.) (Found: N, 13·7; Cl, 17·6%). The base (colourless prisms, m. p. 255° after crystallisation from alcohol) was obtained by treatment of the hydrochloride solution with sodium acetate (Found: N, 17·1%). The *acetyl* derivative (fine needles from water) melted at 298—299° (bath at 240°) (Found: N, 13·5%).

(b) 4-*Nitro*-2-*chloroacetamidophenol*, prepared from 4-nitro-2-aminophenol, crystallised from alcohol in stout hexagonal plates, m. p. 245° (decomp.). It was insoluble in water and ether and sparingly soluble in alcohol and acetone (Found: N, 12·0; Cl, 15·5%).

6-*Nitro*-3-*hydroxy*-1 : 4-*benz*isooxazine formed almost colourless prisms from alcohol; m. p. 233—234°, depressed by admixture with the 7-nitro-compound, m. p. 232°. It was insoluble in water and sparingly soluble in alcohol and acetone (Found: N, 14·6%). On reduction with iron and boiling dilute acetic acid it gave the corresponding amino-derivative, m. p. 255°.

(c) 4-Acetamidophenoxyacetic acid (5·8 g.) mixed with potassium nitrate (2·9 g.) was added to sulphuric acid (30 c.c.) at 10°. After 1 hour the mixture was poured on ice; 2-*nitro*-4-*acetamidophenoxyacetic acid* (5·8 g.; 82%) then crystallised, and was obtained in yellow rhombic plates, m. p. 205—206°, by recrystallisation from water. It was readily soluble in alcohol and sparingly soluble in other organic solvents (Found: N, 10·7. $C_{10}H_{10}O_6N_2$ requires N, 11·0%). On hydrolysis with 7*N*-hydrochloric acid it gave 2-nitro-4-aminophenoxyacetic acid (m. p. 196°; yield, 92%), identical with that obtained by the nitration of 4-aminophenoxyacetic acid (Howard, *loc. cit.*). Both the nitroamino-acid and its acetyl derivative, on reduction by tin and hydrochloric acid, gave 6-amino-3-hydroxy-1 : 4-benz*iso*oxazine, m. p. 255°, not depressed by admixture with the products from (a) and (b).

(C) 7-*Amino*-3-*hydroxy*-1 : 4-*benz*isooxazine.—5-*Nitro*-2-*chloroacetamidophenol*, prepared from 5-nitro-2-aminophenol, crystallised from alcohol in light yellow prisms or tetrahedra, m. p. 233° (decomp.). It was insoluble in cold water (Found: N, 12·1; Cl, 15·5%).

7-*Nitro*-3-*hydroxy*-1 : 4-*benz*isooxazine formed yellow prisms, m. p. 232°, from alcohol (Found: N, 14·0%).

7-*Amino*-3-*hydroxy*-1 : 4-*benz*isooxazine separated in colourless prisms, m. p. 220°, from boiling water. It is insoluble in cold water and ether, slightly soluble in chloroform, and moderately easily soluble in alcohol and acetone (Found: N, 17·3%).

Its *hydrochloride*, m. p. 275—278° (decomp.), formed colourless

prisms, readily soluble in cold water to give a solution neutral to Congo-red (Found: N, 14·0; Cl, 17·5%).

7-*Acetamido*-3-*hydroxy*-1:4-*benz*isooxazine was deposited from hot water in fine needles, m. p. 250°. It is insoluble in cold water, ether, and chloroform and moderately easily soluble in alcohol (Found: N, 13·3%).

(D) 8-*Amino*-3-*hydroxy*-1:4-*benz*isooxazine.—The methods given in the literature for the formation of 6-nitro-2-aminophenol, *viz.*, the de-arsenication of 2-nitro-4-acetamido-3-hydroxyphenylarsinic acid (Benda, *Ber.*, 1914, **47**, 1010) and the nitration of *o*-acetamidophenol in acetic anhydride (King, *loc. cit.*), are not satisfactory for the preparation of large quantities. The following method was therefore used:

3:5-Dinitro-4-hydroxyphenylarsinic acid (120 g.) was refluxed for 1 hour with sodium bisulphite (60 g.) in water (400 c.c.); a further 60 g. of sodium bisulphite in water (100 c.c.) were then added, and the boiling continued for 3 hours. After cooling, the supersaturated solution of sodium sulphate decahydrate was decanted from the cake of 2:6-dinitrophenol, which was crystallised from 50% alcohol (m. p. 60°; yield, 54 g. or 75%). On reduction by ammonium sulphide (Post and Stuckenberg, *Annalen*, 1880, **205**, 85), and crystallisation from alcohol, a 45% yield of 6-nitro-2-aminophenol, m. p. 112—113° (Found: N, 17·9. Calc.: N, 18·2%), was obtained. The *acetyl* derivative was obtained as a monohydrate, m. p. 102—103°; the anhydrous substance melted at 122° (Found: N, 15·0. $C_8H_8O_4N_2$ requires N, 14·9%).

6-*Nitro*-2-*chloroacetamidophenol* crystallised from alcohol in rich yellow rhombs, m. p. 126°, insoluble in water and sparingly soluble in cold acetone (Found: N, 11·8; Cl, 15·6%).

8-*Nitro*-3-*hydroxy*-1:4-*benz*isooxazine formed light yellow prisms, m. p. 255°, from alcohol (Found: N, 14·3%).

8-*Amino*-3-*hydroxy*-1:4-*benz*isooxazine (Found: N, 17·0%) formed colourless prisms, m. p. 180°, from water. It formed a hydrochloride, m. p. 272° (decomp.), and an acetyl derivative, m. p. 257°. This compound and its derivatives were identical with those obtained previously by Dr. I. E. Balaban in this laboratory (p. 3070).

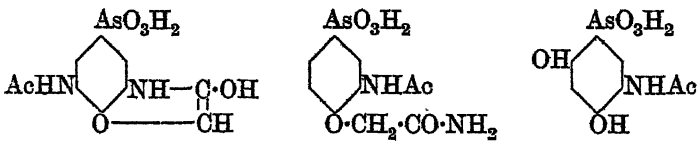
[*Received, September 17th*, 1928.]

CCCCI.—*Heterocyclic Compounds containing Arsenic. Part II. Derivatives of* 1 : 4-*Benz*isooxazine.



By GEORGE NEWBERY, MONTAGUE ALEXANDRA PHILLIPS, and RALPH WILLIAM EWART STICKINGS.

THE therapeutic importance of tryparsamide (sodium hydrogen phenylarsinate 4-glycineamide; I) and of stovarsol (3-acetamido-4-hydroxyphenylarsinic acid; II) suggested the desirability of preparing some hitherto undescribed products of the type of 3-*hydroxy*-1 : 4-*benz*isooxazine-6-*arsinic acid* (III) for pharmacological comparison.

(I.) (II.) (III.)

The arsinic acid (III) was first prepared by reduction of 2-nitrophenoxyacetic acid 4-arsinic acid, the intermediate 2-amino-compound losing water under the conditions employed. It was also obtained from 3-chloroacetamido-4-hydroxyphenylarsinic acid (Raiziss and Fisher, *J. Amer. Chem. Soc.*, 1926, **48**, 1326), which readily loses hydrogen chloride in alkaline solution. Similarly, 3-chloroacetamido-5-acetamido-4-hydroxyphenylarsinic acid yielded 8-*acetamido*-3-*hydroxy*-1 : 4-*benzisooxazine*-6-*arsinic acid* (IV).

(IV.) (V.) (VI.)

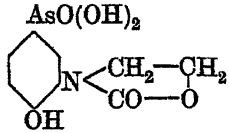
By using α-bromopropionyl chloride and α-bromobutyryl chloride in place of chloroacetyl chloride homologous 2-*alkylbenz*isooxazines were obtained.

2-*Acetamidophenoxyacetic acid* 4-*arsinic acid* and the corresponding *amide* (V), itself of pharmacological interest in its relationship to compounds (I) and (II), were obtained from sodium 3-acetamido-4-hydroxyphenylarsinate by the action of chloroacetic acid and chloroacetamide, respectively. Either, by the action of alkalis or mineral acids, underwent ring closure to form 3-hydroxy-1 : 4-benz*iso*oxazine-6-arsinic acid. Similarly, 2 : 6-diacetamidophenoxyacetic acid 4-arsinic acid, on mild treatment by alkali or acid, yielded the 8-acetamido-derivative (IV); complete hydrolysis

corresponding amino-derivative. Finally, 3-hydroxy-1 : 4-benz*iso*oxazine-6-arsinic acid was obtained from 6-amino-3-hydroxy-1 : 4-benz*iso*oxazine by the Bart reaction.

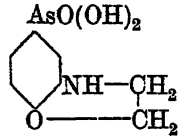
The diminution of toxicity and enhancement of curative effect in mice infected with *Trypanosoma equiperdum* shown by the acetamido-derivative (IV), when administered orally or intravenously, as compared with the parent substance (III) (Ewins and Everett, *Brit. J. Venereal Diseases*, 1927, **3**, 1; 1928, **4**, 181) made it desirable to prepare a number of other 8-derivatives and also some of its eleven structural isomerides.

Attempts to prepare the 8-hydroxy-derivative have, however, proved unsuccessful. None could be isolated by the thermal decomposition of the diazo-derivative of 8-amino-3-hydroxy-1 : 4-benz*iso*oxazine-6-arsinic acid, nor could 3 : 4-dihydroxyphenylarsinic acid or its 5-nitro- or 5-amino-derivative be synthesised as a starting point for ring formation (compare Fargher, J., 1920, **117**, 865).



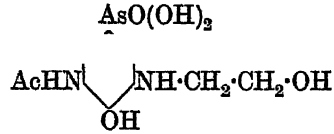
5-*Acetamido*-2 : 4-*dihydroxyphenylarsinic acid* (VI) and the corresponding 3 : 7-*dihydroxy*-1 : 4-*benz*isoo*xazine*-6-*arsinic acid* were also prepared for comparison from 5-nitro-2 : 4-dihydroxyphenylarsinic acid (Bauer, *Ber.*, 1915, **48**, 515).

The nitration of 3-hydroxy-1 : 4-benz*iso*oxazine-6-arsinic acid gave a mixture of 5-*nitro*-, 7-*nitro*-, and 8-*nitro*-3-*hydroxy*-1 : 4-*benz*iso*oxazine*-6-*arsinic acids*. The last was present in 1—3% yield only and was better prepared from 5-nitro-3-amino-4-hydroxyphenylarsinic acid by the chloroacetyl chloride method. The proportion of the 5- and 7-nitro-compounds varied with the temperature of nitration. The 5-isomeride, the formation of which is favoured by low temperature, is the more soluble in water and may be separated by repeated fractional crystallisation, but is best separated by means of its neutral di-ammonium salt. Reduction of each by the method of Jacobs, Heidelberger, and Rolf (*J. Amer. Chem. Soc.*, 1918, **40**, 1580) gave the corresponding amino-compounds, the behaviour of which with nitrous acid gave the clue to their orientation: 5-*amino*-3-*hydroxy*-1 : 4-*benz*iso*oxazine*-6-*arsinic acid* gave an insoluble *triazole* (compare 5-amino-3-hydroxy-1 : 4-benz*iso*oxazine; preceding paper) and the 7-*amino*-compound gave a diazo-compound which coupled normally with alkaline β-naphthol, etc. This conclusion was fully confirmed by dearsenication of the amino-compounds, 5-amino-3-hydroxy-1 : 4-benz*iso*oxazine-6-arsinic acid giving with boiling 5*N*-hydrochloric acid a quantitative yield of 5-amino-3-hydroxy-1 : 4-benz*iso*oxazine. The 7-amino-derivative, treated similarly, gave a small yield of a chlorinated product, m. p. 245°, apparently 6-chloro-7-amino-3-hydroxy-1 : 4-benz*iso*oxazine, but when boiled with sodium bi-



sulphite solution, it de-arsenicated smoothly with the formation in good yield of 7-amino-3-hydroxy-1 : 4-benz*iso*oxazine.

Attempts to prepare 2 : 3-*dihydro*-1 : 4-*benz*iso*oxazine*-6-*arsinic acid* (VIII) by the action of ethylene chlorohydrin on 3-amino-4-hydroxyphenylarsinic acid with the intermediate formation of 3-β-hydroxyethylamino-4-hydroxyphenylarsinic acid were unsuccessful, but the application of the method of Adams and Segur (*J. Amer. Chem. Soc.*, 1923, **45**, 785) led to fair yields of the cyclic acid.



The action of β-chloroethyl chlorocarbonate on sodium 3-amino-4-hydroxyphenylarsinate gave 3-ω-*chlorocarbethoxyamino*-4-*hydroxyphenylarsinic acid*, which, with caustic soda, gave the required acid. It is assumed that there is formed as an intermediate product 2′-hydroxy-2-keto-3-phenyl-4 : 5-dihydro-1 : 3-*iso*oxazole-5′-arsinic acid (VII).

(VII.)

(VIII.)

(IX.)

The mechanism by which this loses carbon dioxide to form the acid (VIII) is obscure, especially since attempts to form 8-acetamido-2 : 3-dihydro-1 : 4-benz*iso*oxazine-6-arsinic acid by an analogous method led to the formation of 5-acetamido-3-β-hydroxyethylamino-4-hydroxyphenylarsinic acid (IX), which was isolated as the corresponding *arseno*-compound readily soluble in caustic alkalis. In this case, therefore, ring closure does not occur.

In the 3-hydroxy-1 : 4-benz*iso*oxazine-8-arsinic acid series, the *parent* substance was obtained from 3-amino-2-hydroxyphenylarsinic acid by the chloroacetyl chloride method and also from 8-amino-3-hydroxy-1 : 4-benz*iso*oxazine by the Bart method. Its amino-derivative was obtained similarly from 3-amino-5-acetamido-2-hydroxyphenylarsinic acid and also from 3 : 5-diamino-2-hydroxyphenylarsinic acid (King, J., 1927, 1050) by chloroacetylation in alkaline solution.

Experimental.

A. 3-*Hydroxy*-1 : 4-*benz*iso*oxazine*-5-*arsinic Acid.*

2-Nitro-3-hydroxyphenylarsinic acid was prepared almost as described in D.R.-P. 256343 (1913). The 2-nitro-3-carbethoxyaminophenylarsinic acid (120 g.), however, was refluxed with 5*N*-sodium hydroxide (600 c.c.) for 1 hour; on acidification (Congo-red), a 50% yield of nearly pure nitrohydroxy-acid was obtained.

It formed rich yellow, hexagonal plates, m. p.* 208° (decomp.) (Found : As, 28·5; N, 5·3. Calc. : As, 28·5; N, 5·3%).

2-Amino-3-hydroxyphenylarsinic acid (compare Fourneau, Tréfouel, and Bénoit, *Bull. Soc. chim.*, 1927, **41**, 499) was obtained in 52% yield by reducing the above nitrohydroxy-acid (55 g. in 330 c.c. of hot water and 58 g. of sodium hydroxide) with glucose (44 g.). The mixture was gently boiled for 5 minutes and, after 1 hour, acidified markedly to Congo-red. Treatment with charcoal, filtration, and neutralisation to Congo-red with 10*N*-sodium hydroxide gave the amino-compound, which, after purification (compare Christiansen, *J. Amer. Chem. Soc.*, 1920, **42**, 2403), formed characteristic wedge-shaped crystals (Found : As, 32·2; N, 5·9. Calc. : As, 32·2; N, 6·0%). The calcium salt formed hexagonal plates and the acetyl derivative rectangular plates, m. p. 207—210° (decomp.) (Found : As, 27·4. Calc. : As, 27·3%).

3-*Hydroxy*-1 : 4-*benzisooxazine*-5-*arsinic Acid.*—2-Amino-3-hydroxyphenylarsinic acid (20 g.), dissolved in 2*N*-sodium hydroxide (50 c.c.), was treated alternately with chloroacetyl chloride (15 c.c. in all) and 25% sodium hydroxide solution at 50°. The mixture was made strongly alkaline and heated at 90° for 10 minutes, more alkali being added as acidity developed. The cyclic *arsinic acid*, obtained in 60% yield on acidification, crystallised from boiling water in colourless rhombs, m. p. 245—248° (decomp.) (Found : As, 27·5; N, 5·0. $C_8H_8O_5NAs$ requires As, 27·5; N, 5·1%). The calcium, barium, and magnesium salts were amorphous, white solids. The orientations of this compound and of 2-nitro-3-carbethoxyaminophenylarsinic acid were confirmed by reduction of the latter by glucose and alkali giving 2 : 3-diaminophenylarsinic acid, m. p. 198° (decomp.) (compare D.R.-P. 256343).

B. 3-*Hydroxy*-1 : 4-*benzisooxazine*-6-*arsinic Acid and its Derivatives.*

Preparation of the Acid.—(a) 2-Nitrophenoxyacetic acid 4-arsinic acid (Christiansen, *J. Amer. Chem. Soc.*, 1922, **44**, 2339), reduced by ferrous hydroxide (Jacobs, Heidelberger, and Rolf, *loc. cit.*), gave the *acid* in 57% yield. It crystallised from boiling water in rhombs, not molten at 300°, and was insoluble in cold water, dilute hydrochloric acid, and the usual organic solvents but soluble in alkalis and alkali carbonates (Found : As, 27·3; N, 5·25%). The calcium salt formed rosettes of needles, but the magnesium salt was amorphous.

(b) 2-*Acetamidophenoxyacetic acid* 4-*arsinic acid.* To 3-acetamido-

* All decomposition points above 200° were determined by rapid heating in a sulphuric acid bath at an initial temperature of 200°.

4-hydroxyphenylarsinic acid (45·5 g.) suspended in water (110 c.c.), sodium hydroxide (20 g.) in water (20 c.c.), followed by chloroacetic acid (16 g.), was added and the mixture was refluxed until it was acid to litmus (¾ hour). A further 7 g. of sodium hydroxide in water (7 c.c.) and chloroacetic acid (8 g.) were added and the boiling was continued until acidity to litmus again developed; the mixture was then acidified to Congo-red and, after cooling, the *arsinic acid* collected. After purification by solution in alkali, addition of acetic acid, filtration from a small amount of unchanged material, and acidification of the filtrate to Congo-red, it crystallised in long pointed needles, not molten at 280° (yield, 66%) (Found: As, 22·5; N, 4·15. $C_{10}H_{12}O_7NAs$ requires As, 22·5; N, 4·2%). The magnesium salt was amorphous.

2-*Acetamidophenoxyacetamide* 4-*arsinic acid* was prepared (yield, 26 g.) in a somewhat similar manner from 3-acetamido-4-hydroxyphenylarsinic acid (27·5 g.) and chloroacetamide (15 + 10 + 5 g.), sodium bicarbonate being added as the alkaline reaction disappeared. It crystallised from water in colourless, hexagonal plates, m. p. 236° (decomp.) (Found: As, 22·3; N, 8·15. $C_{10}H_{13}O_6N_2As$ requires As, 22·6; N, 8·4%) and formed an insoluble amorphous magnesium salt.

2-Acetamidophenoxyacetic acid 4-arsinic acid was heated (10 g.) for 1 hour at 90° with 5*N*-sodium hydroxide (20 c.c.) or refluxed (2 g.) with 4*N*-hydrochloric acid (10 c.c.). On acidification in the former case and on cooling in the latter, 3-hydroxy-1 : 4-benz*iso*oxazine-6-arsinic acid was obtained (yields, 5·5 g. and 1 g., respectively) (Found: As, 27·3; N, 5·0%). The corresponding amide hydrolysed similarly.

(c) 6-Amino-3-hydroxy-1 : 4-benz*iso*oxazine hydrochloride (20 g.) (Newbery and Phillips, preceding paper), dissolved in water (200 c.c.) and hydrochloric acid (20 c.c.; *d* 1·12), was diazotised at 0—5° by sodium nitrite (7 g.) in solution and slowly added to a suspension of copper arsenite (prepared from arsenious oxide, 15 g., water, 40 c.c., sodium hydroxide, 6 g., and copper sulphate, 1·5 g.). The reaction of the mixture was maintained slightly alkaline by the addition of further sodium hydroxide when necessary. After heating with charcoal at 80°, the liquid was filtered, acidified to litmus, filtered from amorphous material after standing for some time, and acidified to Congo-red; the arsinic acid (12·5 g.; 46%) was then precipitated (Found: As, 27·3%).

(d) 3-Chloroacetamido-4-hydroxyphenylarsinic acid (1 g., m. p. 242°), prepared by a modification of Raiziss and Fisher's method (*loc. cit.*), was heated at 90° with sodium hydroxide (slightly more than 1 mol.) in 100 c.c. of water for 15 minutes; on acidification,

the same cyclic arsinic acid (0·6 g.) was obtained (Found: As, 27·5%).

(e) The cyclic acid (Found: As, 27·4; N, 5·1%) was also obtained directly from 3-amino-4-hydroxyphenylarsinic acid as described under 3-hydroxy-1 : 4-benz*iso*oxazine-5-arsinic acid.

2-*Nitrophenoxyacetic Acid* 4-*Dichloroarsine*.—A solution of 2-nitrophenoxyacetic acid 4-arsinic acid (10 g.) in water (10 c.c.) and hydrochloric acid (*d* 1·16; 25 c.c.) was added to a solution of potassium iodide (0·5 g. in 20 c.c. of water) saturated at 10° with sulphur dioxide. This gas was passed into the mixture at 10° for 1 hour and an equal volume of hydrochloric acid was then added. The *dichloroarsine* (7·2 g.; 70%), precipitated as rosettes of plates, was washed with hydrochloric acid and dried in a vacuum over sodium hydroxide. This compound (Found: As, 21·7; N, 4·2; Cl, 20·2. $C_8H_6O_5NCl_2As$ requires As, 21·9; N, 4·1; Cl, 20·75%) is very resistant to aqueous hydrolysis, and attempts to reduce it by stannous chloride or sodium hyposulphite were unsuccessful. Ferrous hydroxide, however, gave a small yield of 3-hydroxy-1 : 4-benz*iso*oxazine 6-arsenoxide which could not be purified.

3-*Hydroxy*-1 : 4-*benzisooxazine* 6-*Arsenoxide*.—Reduction of the corresponding arsinic acid as described above under 2-nitrophenoxyacetic acid 6-dichloroarsine gave a 60% yield of 3-hydroxy-1 : 4-benz*iso*oxazine 4-dichloroarsine. This resisted purification, but gave, on solution in 2*N*-sodium hydroxide and addition of hydrochloric acid until the solution was only faintly acid to Congo-red, the *arsenoxide* in sphæro-crystals, insoluble in water or dilute mineral acids, alkali carbonates or dilute ammonia, but readily soluble in excess of dilute caustic alkali solution (Found: As, 31·3; N, 5·85. $C_8H_6O_3NAs$ requires As, 31·4; N, 5·85%). On treatment with excess of hydrochloric acid the dichloroarsine was obtained.

3 : 3′-*Dihydroxy*-6 : 6′-*arseno*-1 : 4-*benzisooxazine*.—3-Hydroxy-1 : 4-benz*iso*oxazine-6-arsinic acid (2·7 g.), dissolved in water (20 c.c.) and saturated sodium carbonate solution (5 c.c.), was added to a cold solution of magnesium chloride hexahydrate (2 g.) and sodium hyposulphite (10 g.) in water (200 c.c.). The filtered solution, on heating at 50—60° for 1½ hours, gave the *arseno*-compound, which, after being washed with water and dried in a vacuum over sulphuric acid, was a light yellow, amorphous solid, insoluble in water, dilute mineral acids, alkalis, and the ordinary organic solvents (Found: As, 33·2; N, 6·4. $C_{16}H_{12}O_4N_2As_2$ requires As, 33·6; N, 6·3%).

Nitration of 3-*Hydroxy*-1 : 4-*benzisooxazine*-6-*arsinic Acid*.—The arsinic acid (20 g.), intimately mixed with potassium nitrate (7·5 g.), was added to sulphuric acid (70 c.c.) at 0°, 10°, and 30° in three experiments. The mixtures were poured on ice and the dried

nitro-compounds were recrystallised from hot water (500 c.c.), having first been dissolved by the aid of a little sodium hydroxide, followed by acidification. The treatment of the liquors is described below under the 8-nitro-derivative. The recrystallised solid was suspended in water (40 c.c.), and 15% ammonia added until a faint smell of ammonia and a faintly alkaline reaction were produced. The ammonium salt precipitated was collected and washed with a little ice-water; on acidification of its solution in boiling water (100 c.c.), 7-nitro-3-hydroxy-1 : 4-benz*iso*oxazine-6-arsinic acid was obtained. The liquor, which contained a di-ammonium salt, on acidification gave 5-nitro-3-hydroxy-1 : 4-benz*iso*oxazine-6-arsinic acid. The following table indicates the relative yields of the 7- and 5-nitro-isomerides.

Temp. of nitration.	Total yield.	7-Isomeride.	5-Isomeride.
0°	72%	29%	39%
10	75	35	35
30	73	41	28

5-*Nitro*-3-*hydroxy*-1 : 4-*benz*isooxazine-6-*arsinic acid* crystallises from water in yellow prisms (Found: As, 23·7. $C_8H_7O_7N_2As$ requires As, 23·6%). It forms soluble crystalline calcium, barium, and magnesium salts and a sparingly soluble mono-ammonium salt. On reduction with ferrous hydroxide the corresponding *amino*-compound was obtained in 70% yield (Found: As, 26·1; N, 9·7. $C_8H_9O_5N_2As$ requires As, 26·0; N, 9·7%). It crystallises from water in colourless prisms, changing to hexagonal plates, not molten at 300°, is soluble in excess of mineral acids, but is reprecipitated on addition of water. The calcium and barium salts crystallise in white needles, the magnesium salt is micro-crystalline. The sodium salt is sparingly soluble in water but readily soluble in excess of caustic alkali. Attempts to acetylate this arsinic acid in alkaline or acetic acid solution or by the action of acetic anhydride were unsuccessful, the unchanged arsinic acid being obtained in the first two cases. The *triazole* formed white, hexagonal tufts or prisms, m. p. 247° (decomp.), from boiling water (Found: As, 23·7; N, 12·9. $C_8H_6O_5N_3As,H_2O$ requires As, 23·7; N, 13·25%). The calcium, barium, and magnesium salts were all sparingly soluble, amorphous, white solids, the calcium salt being less soluble in boiling than in cold water.

De-arsenication of 5-*amino*-3-*hydroxy*-1 : 4-*benz*isooxazine-6-*arsinic acid*. The amino-arsinic acid (10 g.) was refluxed for 1 hour with 5*N*-hydrochloric acid (50 c.c.). The filtered solution on cooling gave 5·2 g. of 5-amino-3-hydroxy-1 : 4-benz*iso*oxazine hydrochloride. A further 1·1 g. were obtained from the filtrate by treatment with

sodium carbonate and reconversion of the crude base (total yield, 90%). The hydrochloride gave with sodium acetate 5-amino-3-hydroxy-1 : 4-benz*iso*oxazine, m. p. 236° (not depressed by admixture with the synthetic base; preceding paper).

7-*Nitro*-3-*hydroxy*-1 : 4-*benz*iso*oxazine*-6-*arsinic acid* crystallised from boiling water, in which it was sparingly soluble, in long, yellow prisms (Found : As, 24·0%). The calcium, barium, and magnesium salts are soluble yellow solids. On reduction with ferrous hydroxide or glucose and alkali it gave a 70% yield of 7-*amino*-3-*hydroxy*-1 : 4-*benz*iso*oxazine*-6-*arsinic acid*, which formed white prisms, m. p. 258—260° (decomp.), on addition of water to its solution in 25% sulphuric acid (Found : As, 26·0; N, 9·5%). The barium and calcium salts are crystalline (needles), the magnesium salt is amorphous. The *acetyl* derivative crystallised in white prisms, decomp. 275° (Found : As, 22·8; N, 8·5. $C_{10}H_{11}O_6N_2As$ requires As, 22·7; N, 8·5%), and the *urethane* in long needles (Found : As, 21·1; N, 7·7. $C_{11}H_{13}O_7N_2As$ requires As, 20·9; N, 7·8%). Both form amorphous calcium and magnesium salts.

De-arsenication of 7-*amino*-3-*hydroxy*-1 : 4-*benz*iso*oxazine*-6-*arsinic acid*. The amino-arsinic acid (5 g.) was boiled under reflux with sodium bisulphite (3 g.) in water (20 c.c.). Solution was quickly effected and 7-amino-3-hydroxy-1 : 4-benz*iso*oxazine began to separate. After 30 minutes the mixture was made alkaline with sodium carbonate. The product (2·5 g.; 85%) crystallised from water in colourless prisms, m. p. 220°, not depressed by admixture with synthetic 7-amino-3-hydroxy-1 : 4-benz*iso*oxazine (preceding paper).

3 : 7-*Dihydroxy*-1 : 4-*benz*iso*oxazine*-6-*arsinic acid*, obtained in good yield from 5-amino-2 : 4-dihydroxyphenylarsinic acid (Bauer, *loc. cit.*) by chloroacetylation in alkaline solution, crystallised from boiling water in white plates, not molten at 300° (Found : As, 26·1; N, 4·9. $C_8H_8O_6NAs$ requires As, 26·0; N, 4·9%). The barium salt crystallised from boiling water in clusters of colourless prisms, the calcium and magnesium salts were amorphous.

5-*Acetamido*-2 : 4-*dihydroxyphenylarsinic acid*, obtained by acetylation of the above amino-acid in the usual way, formed colourless prisms from water (Found : As, 25·6. $C_8H_{10}O_6NAs$ requires As, 25·9%). The calcium and magnesium salts are amorphous.

8-*Nitro*-3-*hydroxy*-1 : 4-*benz*iso*oxazine*-6-*arsinic Acid*.—(a) The mother-liquors from the crystallisation of the crude nitration product of 3-hydroxy-1 : 4-benz*iso*oxazine-6-arsinic acid gave, on neutralisation with ammonia, addition of excess of magnesium chloride, and heating, a yellow, crystalline precipitate (1 g.) of the magnesium salt. This was converted into the *acid* with dilute

hydrochloric acid (0·7 g. after crystallisation from boiling water) (Found: As, 23·8%).

(b) To 7·5 g. of 3-nitro-5-amino-4-hydroxyphenylarsinic acid (Newbery and Phillips, *loc. cit.*), dissolved in acetone (100 c.c.), was added chloroacetyl chloride (5 c.c.) at 25°. Removal of the bulk of solvent gave *3-nitro-5-chloroacetamido-4-hydroxyphenylarsinic acid* (6·5 g.), which formed yellow prisms, m. p. 200° (decomp.), from boiling water (Found: As, 21·1; Cl, 9·9. $C_8H_8O_7N_2ClAs$ requires As, 21·1; Cl, 10·0%). The magnesium salt is amorphous. On treatment with slightly more than 1 mol. of sodium hydroxide a 60% yield of *8-nitro-3-hydroxy-1:4-benzisooxazine-6-arsinic acid*, identical with the product from (a), was obtained. It formed almost colourless prisms, decomp. 320°. The calcium salt (yellow needles) is moderately easily soluble in cold water, and the magnesium salt (yellow needles) is insoluble, differing in this respect from the magnesium salt of the 5- and 7-nitro-compounds. Attempts to prepare this acid by nitration of 2-acetamidophenoxyacetic acid 4-arsinic acid failed, unchanged material only being obtained.

2:6-*Diacetamidophenoxyacetic acid 4-arsinic acid* was obtained in 75% yield [colourless prisms, m. p. 212° (decomp.), from water] by the action of chloroacetic acid on sodium 3:5-diacetamido-4-hydroxyphenylarsinate (Newbery and Phillips, *loc. cit.*) as described under 2-acetamidophenoxyacetic acid 4-arsinic acid (p. 3055) (Found: As, 19·2; N, 7·1. $C_{12}H_{15}O_8N_2As$ requires As, 19·2; N, 7·2%). The magnesium salt is amorphous. On treatment with boiling 5*N*-sodium hydroxide or 5*N*-hydrochloric acid *8-amino-3-hydroxy-1:4-benzisooxazine-6-arsinic acid*, identical with the product obtained by reduction of the above 8-nitro-derivative with ferrous hydroxide, was obtained. It consisted of staggered plates, not molten at 300°, insoluble in water, but soluble in dilute mineral acids and in alkalis (Found: As, 26·0; N, 9·6%). The sulphate forms rhombs, sparingly soluble in cold water, the barium salt consists of colourless prisms, the calcium salt of white needles, and the magnesium salt is amorphous.

8-Amino-3-hydroxy-1:4-benzisooxazine-6-hydroxychloroarsine hydrochloride was obtained in 90% yield by reduction of the above amino-arsinic acid in 5*N*-hydrochloric acid by sulphur dioxide and potassium iodide, followed by precipitation with excess of hydrochloric acid (*d* 1·16). It formed tiny rhombs or needles (Found: As, 23·0; N, 8·1; Cl, 22·0. $C_8H_8O_3N_2ClAs,HCl$ requires As, 22·9; N, 8·6; Cl, 21·7%) and gave on treatment with water *8-amino-3-hydroxy-1:4-benzisooxazine 6-arsenoxide hydrochloride*, which crystallised in colourless hexagonal plates, soluble in excess of water (Found: As, 25·6; Cl, 11·9. $C_8H_7O_3N_2As,HCl$ requires As, 25·8; Cl, 11·7%).

8:8'-*Diamino*-3:3'-*dihydroxy*-6:6'-*arseno*-1:4-*benzisooxazine* was obtained as a pale yellow, amorphous solid, insoluble in water, dilute caustic alkali solutions, and organic solvents, soluble in dilute hydrochloric acid (Found: As, 30·5; N, 11·7; atomic ratio As: N = 1:2·06. $C_{16}H_{14}O_4N_4As_2$ requires As, 31·5; N, 11·8%).

8-*Acetamido*-3-*hydroxy*-1:4-*benzisooxazine*-6-*arsinic acid*, made either by acetylation of the corresponding amino-acid or by chloroacetylation in alkaline solution of 3-amino-5-acetamido-4-hydroxyphenylarsinic acid (Newbery and Phillips, *loc. cit.*), formed colourless prisms, m. p. 275—280° (decomp.) (Found: As, 22·7; N, 8·5%). The barium and magnesium salts are amorphous. On reduction with sulphur dioxide and potassium iodide as above described, 8-*acetamido*-3-*hydroxy*-1:4-*benzisooxazine*-6-*dichloroarsine* (tufts of white needles) was obtained; this on treatment with water gave the *arsenoxide*, clusters of white needles, insoluble in water, sodium carbonate, or dilute mineral acids, soluble in dilute sodium hydroxide solution and in excess only of 10*N*-ammonia (Found: As, 25·3; N, 9·4. $C_{10}H_9O_4N_2As$ requires As, 25·3; N, 9·5%).

8:8'-*Diacetamido*-3:3'-*dihydroxy*-6:6'-*arseno*-1:4-*benzisooxazine* was obtained as a yellow amorphous solid, stable in air and insoluble in water, dilute mineral acids, alkalis, and organic solvents (Found: As, 26·1. $C_{20}H_{18}O_6N_4As_2$ requires As, 26·8%).

3-*Hydroxy*-1:4-*benzisooxazine*-6-*arsinic Acid* 8-*Glycineamide*.—To 8-amino-3-hydroxy-1:4-benz*iso*oxazine-6-arsinic acid (13 g.) in sodium carbonate solution was gradually added, during 1 hour, chloroacetamide (5 g.) alternately with sodium bicarbonate (5 g.), a faint alkalinity to litmus being maintained. On acidification to Congo-red, the *arsinic acid* was obtained in 60% yield. It formed hexagonal plates from boiling water (Found: As, 21·5; N, 12·05. $C_{10}H_{12}O_6N_3As$ requires As, 21·7; N, 12·2%).

8-*Glycylamino*-3-*hydroxy*-1:4-*benzisooxazine*-6-*arsinic Acid*.—8-Amino-3-hydroxy-1:4-benz*iso*oxazine-6-arsinic acid (20 g.) in 2*N*-sodium hydroxide was treated with chloroacetyl chloride (10 c.c.) and 2*N*-sodium hydroxide by the Schotten–Baumann method. On acidification 8-chloroacetamido-3-hydroxy-1:4-benz*iso*oxazine-6-arsinic acid was precipitated, which, after filtration and washing with water, was dissolved in excess of ammonia (*d* 0·880). After several hours, the mixture was heated to drive off the excess of ammonia and acidified strongly to Congo. Addition of sodium acetate to the filtered solution gave the *glycyl* derivative. Purified by solution in hydrochloric acid and neutralisation with sodium acetate, it formed minute needles, soluble in mineral acids and in alkalis (Found: As, 21·5. $C_{10}H_{12}O_6N_3As$ requires As, 21·7%).

8-*Chloro*-3-*hydroxy*-1:4-*benzisooxazine*-6-*arsinic Acid*.—8-Amino-

3-hydroxy-1 : 4-benz*iso*oxazine-6-arsinic acid (28 g.) was diazotised at 0°, and the diazo-compound was collected and boiled with cuprous chloride (15 g.) dissolved in saturated sodium chloride solution containing a little hydrochloric acid. After treatment with charcoal and cooling, the precipitate obtained (15 g.; 50%) was dissolved in warm alkali and reprecipitated by acid; it then formed yellow prisms, not molten at 280°, sparingly soluble in boiling water (Found: As, 24·1; N, 4·3; Cl, 11·4. $C_8H_7O_5NClAs$ requires As, 24·4; N, 4·6; Cl, 11·5%). The magnesium salt is amorphous.

3-*Hydroxy*-8-*methyl*-1 : 4-*benzisooxazine*-6-*arsinic Acid.*—*The arsination of* o-*cresol.* The method of Christiansen (*J. Amer. Chem. Soc.*, 1923, **45**, 801) for the preparation of 4-hydroxy-3-methylphenylarsinic acid was modified by preliminary distillation of the *o*-cresol–arsenic acid mixture until ½ molecule of water had been removed. The residual mixture was then refluxed with mechanical agitation for 4 hours and worked up as suggested by Christiansen. In this way a 25% yield of sodium 4-hydroxy-3-methylphenylarsinate, *i.e.*, twice that recorded by Christiansen, was obtained.

The sodium salt on nitration (compare Benda and Bertheim, *Ber.*, 1911, **44**, 3450) gave 3-nitro-4-hydroxy-5-methylphenylarsinic acid in 70% yield. On reduction by glucose and alkali as described under 2-amino-3-hydroxyphenylarsinic acid (p. 3054), a 60% yield of the corresponding amino-acid was obtained (compare D.R.-P. 224,953; Fourneau, *Ann. Inst. Pasteur*, 1926, 944). Purified by solution in hydrochloric acid and reprecipitation by sodium acetate, it formed colourless prisms, insoluble in water but readily soluble in alkalis. The monosodium salt (white needles) is sparingly soluble in cold water.

3 : 3′-*Diacetamido*-4 : 4′-*dihydroxy*-5 : 5′-*dimethylarsenobenzene*, obtained by reduction of 3-acetamido-4-hydroxy-5-methylphenylarsinic acid (compare E.P. 254,086), was a yellow, amorphous solid, insoluble in water, mineral acids, and organic solvents, soluble in dilute sodium hydroxide solution and in 50% acetic acid (Found: As, 29·8; N, 6·0. $C_{18}H_{20}O_4N_2As_2$ requires As, 31·4; N, 5·9%).

3-*Hydroxy*-8-*methyl*-1 : 4-*benzisooxazine*-6-*arsinic acid*, made by chloroacetylation in alkaline solution of 3-amino-4-hydroxy-5-methylphenylarsinic acid, crystallised from water in white prisms soluble in alkalis (Found: As, 25·9; N, 4·4. $C_9H_{10}O_5NAs$ requires As, 26·2; N, 4·9%).

3 : 3′-*Dihydroxy*-8 : 8′-*dimethyl*-6 : 6′-*arseno*-1 : 4-*benzisooxazine* was obtained as a yellow, amorphous solid insoluble in water, dilute mineral acids, alkali, and organic solvents, but soluble in 50% acetic acid (Found: As, 30·6; N, 5·6. $C_{18}H_{16}O_4N_2As_2$ requires As, 31·6; N, 5·9%).

8-β-*Hydroxyethylamino*-3-*hydroxy*-1 : 4-*benz*isooxazine-6-*arsinic Acid*.—8-Amino-3-hydroxy-1 : 4-benz*iso*oxazine-6-arsinic acid (15 g.) was treated at 40—50° with β-chloroethyl chlorocarbonate (10 c.c.) and 10*N*-sodium hydroxide. On acidification, 8-ω-chlorocarbethoxyamino-3-hydroxy-1 : 4-benz*iso*oxazine-6-arsinic acid (compare 3-ω-chlorocarbethoxyamino-4-hydroxyphenylarsinic acid, below) separated; it formed white needles from 50% acetic acid. This compound (12 g.) was refluxed for 40 minutes with 5*N*-sodium hydroxide (60 c.c.); on acidification, carbon dioxide was liberated and 8-β-*hydroxyethylamino*-3-*hydroxy*-1 : 4-*benz*isooxazine-6-*arsinic acid* (white prisms from boiling water) separated (Found : As, 22·5; N, 8·4. $C_{10}H_{13}O_6N_2As$ requires As, 22·5; N, 8·4%).

3-*Hydroxy*-8-*carboxy*-1 : 4-*benz*isooxazine-6-*arsinic Acid*.—5-Aminosalicylic acid (made by the method of Armin, Fisher, and Rosenberg, *Ber.*, 1898, **31**, 81) gave, by a modification of the Bart method, a 40% yield of 4-hydroxy-3-carboxyphenylarsinic acid.

3-*Nitro*-4-*hydroxy*-5-*carboxyphenylarsinic acid* (16 g.) separated when a mixture of 4-hydroxy-3-carboxyphenylarsinic acid (20 g.) and potassium nitrate (7·7 g.), added to sulphuric acid (100 c.c.) at 5°, was poured into ice-water (500 c.c.). It formed rich yellow plates of a monohydrate from boiling water and melted at 282—284° (decomp.) when anhydrous. It is moderately easily soluble in cold water and readily soluble in alkalis, giving a deep red solution with excess of sodium hydroxide (Found : H_2O, 5·7; As, 22·8; N, 4·25. $C_7H_6O_8NAs,H_2O$ requires H_2O, 5·5; As, 23·1; N, 4·3%). The magnesium, barium, and calcium salts are amorphous. On reduction with glucose and alkali, 3-*amino*-4-*hydroxy*-5-*carboxyphenylarsinic acid* was obtained; it formed white rhombs, not molten at 300°, from water (Found : As, 27·0; N, 4·8. $C_7H_8O_6NAs$ requires As, 27·1; N, 5·0%). The calcium, barium, and magnesium salts are amorphous. The acid is soluble in excess only of dilute mineral acids, but readily soluble in sodium hydroxide, forming a monosodium salt (needles) which is less soluble in water than the disodium salt.

3-*Acetamido*-4-*hydroxy*-5-*carboxyphenylarsinic acid*, prepared from the above amino-acid by acetylation in alkaline solution, crystallised from boiling water in long, colourless needles, m. p. 250—254° (decomp.). The magnesium and calcium salts are amorphous (Found : As, 23·4; N, 4·6. $C_9H_{10}O_7NAs$ requires As, 23·5; N, 4·4%).

3-*Hydroxy*-8-*carboxy*-1 : 4-*benz*isooxazine-6-*arsinic acid*, made by chloroacetylation in alkaline solution of 3-amino-4-hydroxy-5-carboxyphenylarsinic acid, formed white rhombs, m. p. 300—305° (decomp.), from water. It was soluble in alkalis, giving neutral

solutions, but was sparingly soluble in cold water (Found: As, 23·4; N, 4·5. $C_9H_8O_7NAs$ requires As, 23·6; N, 4·4%).

3-*Hydroxy*-2-*methyl*-1 : 4-*benzisooxazine*-6-*arsinic acid* was obtained from 3-amino-4-hydroxyphenylarsinic acid as described under 3-hydroxy-1 : 4-benz*iso*oxazine-6-arsinic acid, α-bromopropionyl bromide being used instead of chloroacetyl chloride. It formed colourless, pointed needles, not molten at 300°, from water. The calcium salt consists of tufts of needles, and the magnesium salt is amorphous (Found: As, 26·3; N, 4·8. $C_9H_{10}O_5NAs$ requires As, 26·2; N, 4·9%).

3-*Hydroxy*-2-*ethyl*-1 : 4-*benzisooxazine*-6-*arsinic acid*, obtained similarly by means of α-bromobutyryl chloride, formed colourless needles, not molten at 280°, from water. The calcium salt consists of tiny polyhedral crystals, the *magnesium* salt is amorphous (Found: As, 25·2; N, 4·35. $C_{10}H_{12}O_5NAs$ requires As, 24·9; N, 4·65%).

8-*Acetamido*-3-*hydroxy*-2-*methyl*-1 : 4-*benzisooxazine*-6-*arsinic acid*, obtained from 3-amino-5-acetamido-4-hydroxyphenylarsinic acid and α-bromopropionyl bromide, formed white prisms from boiling water. It decomposes at 265° and forms an amorphous magnesium salt (Found: As, 21·7; N, 8·05. $C_{11}H_{13}O_6N_2As$ requires As, 21·8; N, 8·1%).

8-*Acetamido*-3-*hydroxy*-2-*ethyl*-1 : 4-*benzisooxazine*-6-*arsinic acid* formed colourless needles from boiling water (Found: As, 20·7; N, 7·9. $C_{12}H_{15}O_6N_2As$ requires As, 20·9; N, 7·8%).

3-ω-*Chlorocarbethoxyamino*-4-*hydroxyphenylarsinic Acid*.—To 10 g. of 3-amino-4-hydroxyphenylarsinic acid in 30 c.c. of 2*N*-sodium hydroxide at 30° were added alternately β-chloroethyl chlorocarbonate (7 c.c.) and 10*N*-sodium hydroxide, the temperature being maintained between 35° and 40° and the reaction mixture being kept alkaline to litmus but not to phenolphthalein. The filtered solution was acidified to Congo-red, and the *arsinic acid* obtained was purified by acidification of its warm solution in sodium carbonate (yield, 9·5 g.; 63%). It formed colourless rhombic crystals, m. p. 209° (decomp.), insoluble in cold water, the alcohols or in dilute mineral acids, but readily soluble in alkalis (Found: As, 22·1; N, 4·1; Cl, 10·2. $C_9H_{11}O_6NClAs$ requires As, 22·1; N, 4·1; Cl, 10·45%). The magnesium salt is amorphous.

2 : 3-*Dihydro*-1 : 4-*benzisooxazine*-6-*arsinic Acid*.—The above chloro-acid (9 g.) was refluxed for 15 minutes with 30 c.c. of 4*N*-sodium hydroxide. When the filtered solution was acidified to Congo-red, carbon dioxide was evolved and the required *arsinic acid* precipitated. Crystallised by acidification of its hot alkaline solution, it formed white or buff-coloured, hexagonal prisms, molten at 300°, insoluble in water and in most organic

but readily soluble in alkalis (Found: As, 29·1; N, 5·6. $C_8H_{10}O_4NAs$ requires As, 29·0; N, 5·4%). It forms a white, amorphous magnesium salt.

2 : 3-*Dihydro*-1 : 4-*benzisooxazine*-6-*arsenoxide* was obtained by reduction of the corresponding arsinic acid, dissolved in 7 times its weight of hydrochloric acid (*d* 1·16), with sulphur dioxide and potassium iodide as described earlier. On addition of excess of hydrochloric acid, a gum separated, which later crystallised. The crude dichloroarsine was converted into the *oxide* by treatment with water. Purified by addition of hydrochloric acid to its solution in sodium hydroxide, it consisted of a white, amorphous solid insoluble in water, sodium carbonate, ammonia and organic solvents (Found: As, 34·0. $C_8H_8O_2NAs$ requires As, 33·3%). By treatment with excess of hydrochloric acid the dichloroarsine was formed as white prisms.

6 : 6′-*Arseno* (2 : 3-*dihydro*-1 : 4-*benzisooxazine*), obtained from the arsinic acid by hyposulphite reduction in the normal manner, is a yellow amorphous solid insoluble in water, caustic alkalis, dilute mineral acids, and the ordinary organic solvents (Found: As, 35·7; N, 6·6. $C_{16}H_{16}O_2N_2As_2$ requires As, 35·9; N, 6·7%).

3-ω-*Chlorocarbethoxyamino*-5-*acetamido*-4-*hydroxyphenylarsinic acid*, obtained from 3-amino-5-acetamido-4-hydroxyphenylarsinic acid by treatment with β-chloroethyl chlorocarbonate and caustic soda as described under 3-ω-chlorocarbethoxyamino-4-hydroxyphenylarsinic acid, crystallised from 30% acetic acid in long needles, m. p. 189° (decomp.). Its magnesium salt is amorphous (Found: As, 19·15; N, 7·0; Cl, 8·65. $C_{11}H_{14}O_7N_2ClAs$ requires As, 18·9; N, 7·1; Cl, 8·9%).

3 : 3′-*Di*(β-*hydroxyethylamino*)-5 : 5′-*diacetamido*-4 : 4′-*dihydroxyarsenobenzene*.—3-ω-Chlorocarbethoxyamino-5-acetamido-4-hydroxyphenylarsinic acid (5 g.) was heated in the water-bath for 30 minutes with 10% sodium hydroxide solution (20 c.c.). The mixture was then cooled and added to a solution of sodium hyposulphite (20 g.) and magnesium chloride hexahydrate (2 g.) in water (200 c.c.). After 2 hours' heating at 55°, the *arseno*-compound was collected, washed, and dried at 90°. It is a stable, pale yellow, amorphous solid, insoluble in water, sodium carbonate, dilute hydrochloric acid, or the usual organic solvents, but readily soluble in dilute caustic alkali solutions (Found: As, 26·2; N, 9·4. $C_{20}H_{26}O_6N_4As_2$ requires As, 26·4; N, 9·8%).

C. 3-*Hydroxy*-1 : 4-*benzisooxazine*-8-*arsinic Acid*.

6-Nitro-2-aminophenol, obtained as described in the previous paper, gave, by a modification of the Bart reaction, a 50% yield of

3-nitro-2-hydroxyphenylarsinic acid (compare Fourneau, Tréfouel, and Bénoit, *loc. cit.*), which formed characteristic yellow nodules, m. p. 252—254° (decomp.) (Found: As, 28·8%). The calcium, barium, and magnesium salts were yellow, amorphous solids. On reduction as described under 2-amino-3-hydroxyphenylarsinic acid, a 62% yield of 3-amino-2-hydroxyphenylarsinic acid (m. p. over 300°; magnesium and calcium salts amorphous), was obtained (Found: As, 32·2%). 3-Acetamido-2-hydroxyphenylarsinic acid (compare Fourneau, etc., *loc. cit.*) forms stout plates, m. p. 205° (decomp.), from water. Its calcium salt is amorphous and its barium salt microcrystalline (Found: As, 27·5; N, 5·0. Calc.: As, 27·3; N, 5·1%).

3-*Hydroxy*-1 : 4-*benzisooxazine*-8-*arsinic acid*, obtained either from 3-amino-2-hydroxyphenylarsinic acid by chloroacetylation in alkaline solution as described above under the isomeric acids, or by the Bart reaction on 8-amino-3-hydroxy-1 : 4-benz*iso*oxazine (see previous paper), formed white needles, m. p. 298° (decomp.), from boiling water (Found: As, 27·5; N, 5·0%). The magnesium salt consists of clusters of needles, the calcium salt of characteristic, many-sided nodules, and the barium salt of white prisms. The sodium salt forms white needles readily soluble in water to give a solution neutral to litmus.

6-*Amino*-3-*hydroxy*-1 : 4-*benz*isooxazine-8-*arsinic Acid*.—This was obtained in good yield from 3 : 5-diamino-2-hydroxyphenylarsinic acid (King, *loc. cit.*) by chloroacetylation in alkaline solution as in the preparation of 3-hydroxy-1 : 4-benz*iso*oxazine-5-arsinic acid (p. 3054), an excess of chloroacetyl chloride being used. Presumably the intermediately-formed 6-chloroacetamido-3-hydroxy-1 : 4-benz*iso*oxazine-8-arsinic acid is decomposed during the reaction.

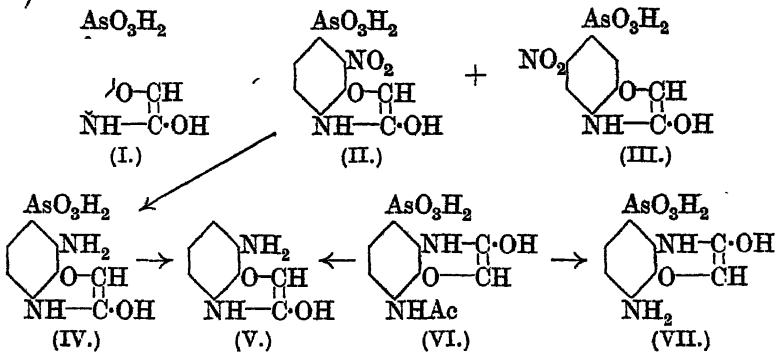
6-*Amino*-3-*hydroxy*-1 : 4-*benz*isooxazine-8-*arsinic acid* (Found: As, 26·0; N, 9·6%), obtained as above or by hydrolysis of the acetyl derivative, formed white prisms, not molten at 300°, from water. It is insoluble in cold water and organic solvents, but readily soluble in alkalis and in dilute hydrochloric and sulphuric acids, the sparingly soluble hydrochloride (prisms) and sulphate (rhombs) separating on standing. The barium salt forms white prisms, and the calcium salt rhombs; the magnesium salt is amorphous or microcrystalline. This acid is more basic than 7- and 5-amino-3-hydroxy-1 : 4-benz*iso*oxazine-6-arsinic acids, but less basic than 8-amino-3-hydroxy-1 : 4-benz*iso*oxazine-6-arsinic acid: 2·5 g. of the 6-amino-8-arsinic acid, 8-amino-6-arsinic acid, 7-amino-6-arsinic acid, and 5-amino-6-arsinic acid, suspended in 10 c.c. of water require, respectively, 2·5, 4·3, 7, and 15 c.c. of 10*N*-sulphuric acid.

for solution. Only the solutions of the last two amino-acids are hydrolysed by addition of water.

6-*Acetamido*-3-*hydroxy*-1 : 4-*benzisooxazine*-8-*arsinic acid*, obtained in 80% yield by acetylation of the corresponding amino-acid or in 50% yield by chloroacetylation in alkaline solution of 3-amino-5-acetamido-2-hydroxyphenylarsinic acid (Newbery and Phillips, *loc. cit.*), consists of white needles, not molten at 300°. It is insoluble in cold, sparingly soluble in boiling water (Found : As, 22·9; N, 8·5%). The magnesium salt is a white, amorphous solid.

6 : 6′-*Diacetamido*-3 : 3′-*dihydroxy*-8 : 8′-*arseno*-1 : 4-*benzisooxazine*, made by hyposulphite reduction of the above arsinic acid, is a pale yellow, amorphous solid, fairly stable in air. It is insoluble in water, alkalis, dilute mineral acids, and ordinary organic solvents (Found : As, 25·7; N, 9·5. $C_{20}H_{18}O_6N_4As_2$ requires As, 26·8; N, 10·0%).

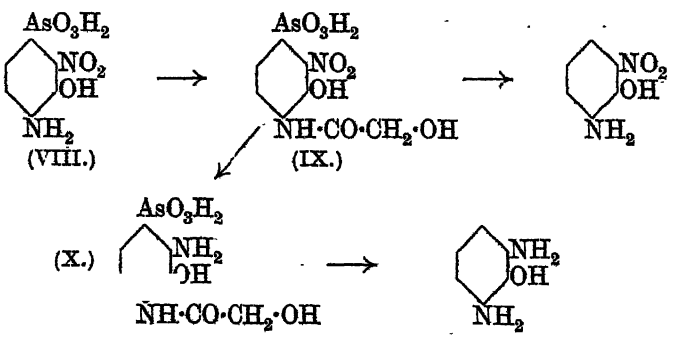
RESEARCH LABORATORIES, MESSRS. MAY & BAKER, LTD.,
WANDSWORTH, S.W. 18. [*Received, September 17th*, 1928.]



CCCCII.—*Heterocyclic Compounds containing Arsenic. Part III. Some Derivatives of 4-Amino-3-hydroxyphenylarsinic Acid.*

By ISIDORE ELKANAH BALABAN.

IN Part II (preceding paper) the heterocyclic compounds described were prepared mainly from 3-amino-4-hydroxyphenylarsinic acid. Similar derivatives of 4-amino-3-hydroxyphenylarsinic acid will now be described. Ewins and Everett (*Brit. J. Venereal Diseases*, 1927, **3**, 1) have shown that 3-hydroxy-1 : 4-benz*iso*oxazine-6-arsinic acid and its 8-acetamido-derivative have $C/T = 1/25$ and 1/80, respectively, *per os*, ratios sufficiently good to render desirable the study of further compounds of the same series.



When 4-amino-3-hydroxyphenylarsinic acid is treated with chloroacetyl chloride in aqueous sodium hydroxide solution, 3-*hydroxy*-1 : 4-*benzisooxazine*-7-*arsinic acid* (I) (compare Aschan, *Ber.*, 1887, **20**, 1523) is obtained. On nitration of this acid a mixture of two isomeric nitro-derivatives is obtained. These represent 8-*nitro*-3-*hydroxy*-1 : 4-*benzisooxazine*-7-*arsinic acid* (II) and 6(?)-*nitro*-3-*hydroxy*-1 : 4-*benzisooxazine*-7-*arsinic acid* (III), respectively, because 8-*amino*-3-*hydroxy*-1 : 4-*benzisooxazine*-7-*arsinic acid* (IV), the reduction product of (II), on de-arsenication with 16% hydrochloric acid yields 8-*amino*-3-*hydroxy*-1 : 4-*benzisooxazine* (V). This amine is also obtained by the acid hydrolysis of 8-*acetamido*-

3-*hydroxy*-1 : 4-*benzisooxazine*-5-*arsinic acid* (VI) (compare Benda, *Ber.*, 1914, **47**, 995), which is prepared from 2-amino-4-acetamido-3-hydroxyphenylarsinic acid (Balaban, this vol., p. 809), whereas the alkaline hydrolysis proceeds normally, giving 8-*amino*-3-*hydroxy*-1 : 4-*benzisooxazine*-5-*arsinic acid* (VII).

Although (III) has not been submitted to similar treatment owing to lack of material, nevertheless it is reasonable to assume *op*-nitration of the benz*iso*oxazine arsinic acid under examination. Attempts to de-arsenicate the nitro-compounds by acid hydrolysis were unsuccessful.

An unexpected result was obtained by the action of chloroacetyl chloride on 2-nitro-4-amino-3-hydroxyphenylarsinic acid (VIII), for the only product isolated was 2-*nitro*-4-ω-*hydroxyacetamido*-3-*hydroxyphenylarsinic acid* (IX). This is in contrast with the behaviour of 5-*nitro*-3-*amino*-4-*hydroxyphenylarsinic acid* (Part II), which gives a benz*iso*oxazine derivative normally, and it can only be concluded that the influence of the nitro-group in this case is strong enough to inhibit ring closure. This fact was definitely

established by (*a*) de-arsenication of (IX) and subsequent isolation of 2-nitro-6-aminophenol, and (*b*) its reduction to 2-*amino*-4-ω-*hydroxyacetamido*-3-*hydroxyphenylarsinic acid* (X) and de-arsenication.

the 2 : 6-diaminophenol produced being identified in the forms of its di- and tri-acetyl derivatives.

When 3-nitrobenzoxazolone-5-arsinic acid, which is the main nitration product of benzoxazolone-5-arsinic acid, was boiled with 2*N*-sodium hydroxide for 3 hours, ammonia was evolved and the only identifiable product was *5-nitro-4-amino-3-hydroxyphenylarsinic acid*, obtained in 41·0% yield. With hydrochloric acid, only unchanged material was recovered.

Experimental.

3-Hydroxy-1 : 4-benzisooxazine-7-arsinic Acid (I).—4-Amino-3-hydroxyphenylarsinic acid (23·3 g.), dissolved in 2*N*-sodium hydroxide, was treated with chloroacetyl chloride (15 c.c.); the chloroacetyl derivative which separated was redissolved by further additions of alkali. After heating on the water-bath for ½ hour, the solution was acidified with hydrochloric acid, 12·9 g. of the desired *acid* (yield, 47·2%) being obtained. This acid crystallises from boiling water (10 parts) in rhomboids containing $1H_2O$, and is identical with the compound obtained from 7-amino-3-hydroxy-1 : 4-benz*iso*oxazine by the Bart–Schmidt reaction (Found on air-dried material: loss at 100°, 6·2. $C_8H_{10}O_5NAs,H_2O$ requires H_2O, 6·2%. Found on material dried at 100°: As, 27·1; N, 4·9. $C_8H_{10}O_5NAs$ requires As, 27·4; N, 5·1%). It is soluble in hot alcohol and moderately easily soluble in glacial acetic acid, from which it crystallises in rhomboids. The calcium salt crystallises in bunches of spikes, the magnesium and barium salts are amorphous.

Nitration of 3-Hydroxy-1 : 4-benzisooxazine-7-arsinic Acid.—The acid (10 g.) was nitrated at 0°, and on pouring the solution on ice and keeping, 6·6 g. of nitro-compounds, m. p. 275° (decomp.), were obtained. The mother-liquor deposited a further 1·8 g. (total yield, 72·4%). After recrystallisation from water the two crops were obtained in very pale yellow needles and colourless rectangular plates, respectively, representing the 8-nitro- and 6(?)-nitro-3-hydroxy-1 : 4-benz*iso*oxazine-7-arsinic acids.

8-Nitro-3-hydroxy-1 : 4-benzisooxazine-7-arsinic acid (II) (Found on air-dried material: As, 23·8; N, 8·7. $C_8H_7O_7N_2As$ requires As, 23·6; N, 8·8%) and *6(?)-nitro-3-hydroxy-1 : 4-benzisooxazine-7-arsinic acid* (III) (Found on air-dried material: As, 23·6. N, 8·5%) both decompose at 280°, the latter violently. Both acids are sparingly soluble in glacial acetic acid, from which they crystallise in rods and rectangular plates, respectively, and are insoluble in alcohol. The magnesium salts are amorphous, but the calcium salt of the 6(?)-nitro-acid crystallises in bunches of needles and the barium salt in diamond-shaped crystals.

8-*Amino*-3-*hydroxy*-1 : 4-*benzisooxazine*-7-*arsinic acid* (IV), prepared from (II) by the ferrous sulphate method (yield, 66·6%), crystallised from boiling 2*N*-acetic acid (20 parts) in clusters of almost colourless, fine, silky needles containing $\frac{3}{4}H_2O$ (Found on air-dried material: loss at 100°, 4·7; As, 25·0; N, 9·2. $C_8H_9O_5N_2As,\frac{3}{4}H_2O$ requires $\frac{3}{4}H_2O$, 4·5; As, 24·9; N, 9·3%. Found on substance dried at 100°: As, 26·0. $C_8H_9O_5N_2As$ requires As, 26·0%). It is readily soluble in 2*N*-hydrochloric acid and 80% formic acid, sparingly soluble in glacial acetic acid, and insoluble in alcohol. After diazotisation it gives with sodium β-naphthoxide a bright red solution. The barium salt forms fine needles, the calcium salt is micro-crystalline, and the magnesium salt amorphous.

De-arsenication.—When the amino-acid (2 g.) just described was heated with 16% hydrochloric acid (10 c.c.) for 1 hour, the compound of m. p. 180° (see p. 3070) was obtained in 61·4% yield.

8-*Acetamido*-3-*hydroxy*-1 : 4-*benzisooxazine*-7-*arsinic acid*, obtained by acetylation of the above acid in alkaline solution, crystallised from water in colourless, silky, anhydrous needles (Found on air-dried material: As, 22·6; N, 8·4. $C_{10}H_{11}O_6N_2As$ requires As, 22·7; N, 8·5%), readily soluble in 80% formic acid, almost insoluble in glacial acetic acid, and insoluble in alcohol. The magnesium salt is gelatinous and the calcium salt separates in clusters of fine needles.

2-*Nitro*-4-ω-*hydroxyacetamido*-3-*hydroxyphenylarsinic Acid* (IX).—2-Nitro-4-amino-3-hydroxyphenylarsinic acid (20 g.), chloroacetylated in the usual manner, gave 13·5 g. (yield, 59·2%) of material which crystallised from water, in which it was moderately easily soluble, in golden-brown anhydrous plates, efferv. 210° (Found: As, 22·1; N, 8·2. $C_8H_9O_8N_2As$ requires As, 22·3; N, 8·3%). The *acid* is sparingly soluble in alcohol and in glacial acetic acid, from which it crystallises in plates, and forms a rich red solution in aqueous sodium hydroxide.

De-arsenication. 0·5 G. of the nitro-acid, heated with 16% hydrochloric acid (2·5 c.c.) for ½ hour, gave 2-nitro-6-aminophenol, m. p. 110° (alone or mixed with an authentic specimen).

2-*Amino*-4-ω-*hydroxyacetamido*-3-*hydroxyphenylarsinic Acid* (X).—The corresponding nitro-acid on reduction gave the *amino-acid* (85·5% yield), which crystallised from water (20 parts) in almost colourless clusters of stout anhydrous prisms (Found: As, 25·2; N, 9·1. $C_8H_{11}O_6N_2As$ requires As, 24·5; N, 9·1%). It is soluble in excess of 2*N*-hydrochloric acid (giving a red solution after diazotisation and coupling with alkaline β-naphthol), moderately easily soluble in glacial acetic acid, very sparingly soluble in alcohol, readily soluble in 80% formic acid. The magnesium, calcium, barium salts are amorphous.

De-arsenication. The product of de-arsenication gave, after acetylation, the triacetyl derivative of 2 : 6-diaminophenol, m. p. *ca.* 200°, which after treatment with alkali gave 2 : 6-diacetamidophenol, m. p. 160°.

4-ω-*Hydroxyacetamido*-2-*acetamido*-3-*hydroxyphenylarsinic acid*, prepared by acetylation of the above acid, crystallised from water, in which it was moderately easily soluble, in fine, colourless, silky, anhydrous needles (Found on air-dried material: As, 22·0; N, 7·9. $C_{10}H_{13}O_7N_2As$ requires As, 21·7; N, 8·0%). It is moderately easily soluble in glacial acetic acid, but insoluble in alcohol. The magnesium salt is amorphous.

8-*Acetamido*-3-*hydroxy*-1 : 4-*benzisooxazine*-5-*arsinic Acid.*—10·5 G. of 2-amino-4-acetamido-3-hydroxyphenylarsinic acid, chloroacetylated as previously described, gave 2·95 g. (yield, 24·6%) of the *acid*, which crystallised from 2*N*-acetic acid, in which it was moderately easily soluble, in fine, colourless, silky, anhydrous needles (Found on air-dried substance: As, 23·1; N, 8·6. $C_{10}H_{11}O_6N_2As$ requires As, 22·7; N, 8·5%). It is readily soluble in 80% formic acid, moderately easily soluble in glacial acetic acid, very sparingly soluble in boiling water, and insoluble in alcohol. The magnesium salt is amorphous and the calcium salt forms acicular crystals.

8-*Amino*-3-*hydroxy*-1 : 4-*benzisooxazine.*—0·8 G. of the above acid was heated with 16% hydrochloric acid (4·0 c.c.) for ½ hour. On cooling, 0·5 g. of the *benzisooxazine hydrochloride* separated. It crystallises in anhydrous, stout, hexagonal prisms from water, in which it is readily soluble when hot, chars at 270°, and decomposes at *ca.* 300° (eff.). Its aqueous solution is acid to Congo-red (Found on air-dried material: Cl, 17·4; N, 14·4. $C_8H_8O_2N_2$,HCl requires Cl, 17·7; N, 14·0%). It diazotises normally. The *base* crystallises from hot water, in which it is fairly soluble, in long, colourless, silky, anhydrous needles, m. p. 180° (Found on air-dried material: N, 16·9. $C_8H_8O_2N_2$ requires N, 17·1%). It is readily soluble in alcohol and acetone, sparingly soluble in ether, and almost insoluble in benzene. The nitrate (long rectangular prisms) and the sulphate (short stout rods) are very soluble in water. The *acetyl* derivative crystallises from water, in which it is sparingly soluble, in long, colourless, silky anhydrous needles, m. p. 257° (Found on air-dried material: N, 13·6. $C_{10}H_{10}O_3N_2$ requires N, 13·6%). When the amine or its acetyl derivative is warmed with concentrated nitric and sulphuric acids, a bright blue colour develops; the amine hydrochloride produces an olive-green colour.

8-*Amino*-3-*hydroxy*-1 : 4-*benzisooxazine*-5-*arsinic Acid.*—2 G. of the corresponding acetyl derivative were hydrolysed with 2*N*-sodium

hydroxide (20 c.c.) for ½ hour. This *acid* crystallises from water, in which it is sparingly soluble, in long rectangular prisms which contain $\frac{1}{2}H_2O$ not lost at 100° (Found on material dried at 100°: As, 24·8; N, 9·6. $C_8H_9O_5N_2As,\frac{1}{2}H_2O$ requires As, 25·2; N, 9·4%). It is readily soluble in 2*N*-hydrochloric acid and diazotises normally. It is soluble in 80% formic acid, sparingly soluble in glacial acetic acid, from which it crystallises in rectangular prisms, and insoluble in alcohol. The magnesium salt crystallises in irregular plates, the calcium and barium salts are amorphous.

Benzoxazolone-5-arsinic Acid.—4-Amino-3-hydroxyphenylarsinic acid (20 g.) was dissolved in 2*N*-sodium hydroxide and treated with carbonyl chloride; the solid which separated (yield, 20·6 g.; 93%) was insoluble in hydrochloric acid and after treatment with nitrous acid did not couple with sodium β-naphthoxide. This acid, mentioned in E.P. 214,628, crystallises from boiling water (25 parts) in long, colourless, anhydrous, boat-shaped plates (Found: As, 29·1; N, 5·5. Calc. for $C_7H_6O_5NAs$: As, 29·0; N, 5·4%). It is very sparingly soluble in glacial acetic acid and alcohol, but moderately easily soluble in 80% formic acid. The magnesium salt is microcrystalline.

Nitration of Benzoxazolone-5-arsinic Acid.—The acid (8·63 g.) was nitrated at 0°, and the mixture poured on ice; 6·7 g. (yield, 66·1%) of product were collected. A prolonged fractional crystallisation from water gave evidence of the presence of more than one compound, but actually only one substance was obtained pure, the final mother-liquor giving material which was an inseparable mixture.

3-Nitrobenzoxazolone-5-arsinic acid, the subject of U.S.P. 1539798, crystallises from boiling water (20 parts) in almost colourless, stout, anhydrous, quadrilateral prisms (Found on air-dried material: As, 24·8; N, 9·1. Calc. for $C_7H_5O_7N_2As$: As, 24·7; N, 9·2%). It is moderately easily soluble in glacial acetic acid and 2*N*-acetic acid, from which it crystallises in quadrilateral prisms, sparingly soluble in 80% formic acid, and almost insoluble in alcohol.

5-Nitro-4-amino-3-hydroxyphenylarsinic Acid.—4 G. of the above acid were heated with 2*N*-sodium hydroxide (40 c.c.) for 4 hours, ammonia being evolved and the solution acquiring a deep reddish-violet colour. On acidification the desired *acid* was obtained in 41·0% yield. The mother-liquor gave with ferric chloride an intense bluish-green colour, indicating the presence of a pyrocatechol derivative; only a trace of crystalline material, however, could be isolated from it. This acid crystallises from water in bright yellow spikes containing $1H_2O$ which is not lost at 100° (Found on material dried at 100°: As, 25·7; N, 8·8. $C_6H_7O_6N_2As,H_2O$ requires As,

25·4; N, 9·4%). It is sparingly soluble in water, almost insoluble in glacial acetic acid and alcohol, soluble in formic acid and concentrated hydrochloric acid, and diazotises normally. The calcium salt separates in laminæ.

6-*Nitrobenzoxazolone*-5-*arsinic Acid*.—2-Nitro-4-amino-3-hydroxyphenylarsinic acid (6 g.) was treated with carbonyl chloride as previously described; the collected solid (3·9 g.; 59·6%) was insoluble in hydrochloric acid and after treatment with nitrous acid did not couple with sodium β-naphthoxide. This *acid* crystallises from water, in which it is very sparingly soluble, in long, pale brown, anhydrous, hexagonal plates (Found on material dried at 100°: As, 24·7; N, 9·2. $C_7H_5O_7N_2As$ requires As, 24·7; N, 9·2%). It is almost insoluble in alcohol and glacial acetic acid. The magnesium and barium salts are microcrystalline.

6-*Aminobenzoxazolone*-5-*arsinic Acid*.—The above nitro-acid on reduction gave an 82·4% yield of the *amino-acid*, which crystallised from 30 volumes of boiling water in colourless hexagonal laminæ, containing $1H_2O$ which is lost at 100° (Found on air-dried material: loss at 100°, 6·0; As, 25·8. $C_7H_7O_5N_2As,H_2O$ requires H_2O, 6·2; As, 25·7%. Found on material dried at 100°: As, 27·0; N, 10·5. $C_7H_7O_5N_2As$ requires As, 27·4; N, 10·2%). It is soluble in concentrated hydrochloric acid and diazotises normally, is readily soluble in 80% formic acid, very sparingly soluble in glacial acetic acid, and insoluble in alcohol. The magnesium, calcium, and barium salts are all microcrystalline.

6-*Acetamidobenzoxazolone*-5-*arsinic acid*, prepared by acetylation of the above acid, crystallised from 2*N*-acetic acid in colourless anhydrous leaflets (Found on air-dried material: As, 23·9. $C_9H_9O_6N_2As$ requires As, 23·7%). It is sparingly soluble in glacial acetic acid, from which it crystallises in minute rods. The magnesium salt is amorphous and the calcium salt microcrystalline.

6-*Acetamidobenzoxazolone*-3-*arsinic Acid*.—2-Amino-4-acetamido-3-hydroxyphenylarsinic acid (10 g.) was treated with carbonyl chloride as previously described. The product (9·0 g.; 81·8%) was insoluble in hydrochloric acid and after treatment with nitrous acid gave no coloration with sodium β-naphthoxide. This *acid* crystallises in anhydrous colourless leaflets from 2*N*-acetic acid, in which it is sparingly soluble (Found on air-dried material: As, 23·9; N, 8·7. $C_9H_9O_6N_2As$ requires As, 23·7; N, 8·9%). It is fairly readily soluble in water and almost insoluble in glacial acetic acid. The magnesium, calcium, and barium salts are amorphous.

The author desires to thank Mr. R. H. Klein, F.I.C., for the analyses recorded in this and the previous paper (this vol., p. 809),

and Mr. J. G. Everett, B.Sc., A.I.C., for the experimental results obtained with mice (see Ewins and Everett, *Brit. J. Venereal Diseases*, 1928, **4**, 181) and also for the results detailed in the previous paper (*loc. cit.*).

WANDSWORTH, S.W. 18. [*Received, September 17th*, 1928.]

CCCCIII.—*The Chlorination of Anilides. Part V. The Significance of Velocity Measurements in Relation to the Problem of Benzene Substitution* (continued).

By ALAN EDWIN BRADFIELD and BRYNMOR JONES.

1. *The Critical Energy Increments for the Reactions of* p-*Disubstituted Benzenes.*

IN an attempt to link qualitative theories of the mechanism of nuclear activation with the kinetic theories of reaction which have found expression in the conception of the critical energy increment, the authors recently considered (this vol., p. 1006) the application to aromatic substitution reactions of the equation for reaction velocity $k = PSZe^{-E/RT}$ (where Z is the collision number, E the critical increment, and S and P are probability terms depending on the shapes and the "phase conditions" of the molecules). Expressions of the type $\log (k_o/2k_p)_{T_1} = (T_2/T_1) \log (k_o/2k_p)_{T_2}$ were deduced and employed to calculate the effect of temperature on the proportions of isomerides formed by further substitution of mono- and di-substituted benzene derivatives.* The success of our calculation warranted the provisional rejection of phase factors (P) and steric factors (S), the product of which differed for the alternative points of entrance of the substituent, and justified the adoption of the hypothesis that the ratio of the isomerides formed is governed entirely by the difference of energy of activation of the positions

* The authors regret that at the time they were completely unaware that, so long ago as 1913, in a paper of which no abstract appeared in the *Chemisches Zentralblatt*, and which appears to have been generally overlooked by those interested in the problem of benzene substitution (compare, *e.g.*, the discussion of the effect of temperature by Holleman, *Chem. Reviews*, 1924, **1**, 221; Lapworth and Robinson, *Mem. Manchester Phil. Soc.*, 1928, **72**, 43), Scheffer (*Proc. K. Akad. Wetenschap. Amsterdam*, 1913, **15**, 1118) had not only deduced exactly the same expression from a thermodynamic standpoint, and carried out a similar calculation, but had also anticipated the authors' pointing out that Holleman's empirical "product rule" implies the additivity of energies of activation. They now wish to direct attention to Scheffer's undisputed priority in this connexion.

concerned. As a result of extending this hypothesis to a series of closely related ethers p-RO·C_6H_4·X, to the rate of chlorination of which relations of the type* $k^{OR_1}_{X_1}/k^{OR_1}_{X_2} = k^{OR_2}_{X_1}/k^{OR_2}_{X_2}$ apply, we were led to the conclusion that the groups already present contribute additively to the energy of activation of the position in which the new substituent will enter. By a similar treatment of velocity ratios, Hückel (*Ber.*, 1928, **61**, 1517) has recently shown, *inter alia*, that the different rates of saponification of esters of *cis*- and *trans*-isomeric substituted *cyclo*hexanols find no reasonable explanation in "steric hindrance," thus affording indirect support for our hypothesis.

According to the theory of kinetic activation, the energy condition which must be satisfied before the molecules A and B can react in a given medium is that the sum of the kinetic energies of translation, $E_A + E_B$, of the two colliding molecules should exceed E, the critical energy increment, and conclusions which appear to be of some importance may be reached by a more detailed examination of the significance of E. It is to be remembered that E is not a characteristic of either one substance or the other, but of the reaction between the two. It would seem, however, that this amount of energy E is the minimum required to bring about some essential change in the sub-atomic structure of both A and B before the molecules can become articulated to form an intermediate complex which, by a rearrangement of electronic orbits, breaks down to the new molecules C and D. A fraction, ε_1, then, of E represents the energy required to "*activate*" A, whilst ε_2 is required to "activate" B, there being no necessity to assume any fixed relationship between ε_1 and E_A, and ε_2 and E_B. For the reaction of A with a second reagent M, similarly

$$\varepsilon'_1 + \varepsilon'_2 = E' \gtreqless E'_A + E_M$$

and again there need be no other relationship between ε'_1 and E'_A, and ε'_2 and E_M than that expressed above. Further, there is no *a priori* reason to suppose there is any simple relationship between ε_1 and ε'_1.

The E terms for the expression for the velocity coefficients for the chlorination of p-MeO·C_6H_4·X and p-EtO·C_6H_4·X given in Part IV may now be expanded on these lines, thus:

$$\log_e(k^{OMe}_{p\text{-}X}/2Z) = -(\varepsilon_{OMe} + E_{p\text{-}X} + \varepsilon_{Cl_2})/RT$$
$$\log_e(k^{OEt}_{p\text{-}X}/2Z) = -(\varepsilon_{OEt} + E_{p\text{-}X} + \varepsilon'_{Cl_2})/RT$$

where $(\varepsilon_{OMe} + E_{p\text{-}X})$ is the energy required to [illegible] the ortho-carbon atom, ε_{OMe} representing the effect of the [illegible] group, and $E_{p\text{-}X}$ representing the modifying influence [illegible] atom X;

* For notation, see Bradfield and [illegible]

($\varepsilon_{OEt} + E_{p\text{-}X}$) has a similar significance. ε_{Cl_2} and ε'_{Cl_2} represent the energy required to activate the chlorine molecule for the reaction with the first and second substances respectively. The experimental work discussed in Part IV requires that (1) $E_{p\text{-}X}$ is the same in both cases, and (2) ($\varepsilon_{OMe} + \varepsilon_{Cl_2}$) and ($\varepsilon_{OEt} + \varepsilon'_{Cl_2}$) are independent of the chemical nature of X, for then

$$\log_e k_{p\text{-}X}^{OEt}/k_{p\text{-}X}^{OMe} = \{(\varepsilon_{OMe} - \varepsilon_{OEt}) + (\varepsilon_{Cl_2} - \varepsilon'_{Cl_2})\}/RT \quad . \quad . \quad (1)$$

is independent of the nature of X.

Consider now the equations for the rates of nitration of 4-ethoxyanisole in positions 2 and 3 respectively :

$$\log_e(k_2/2Z) = -(\varepsilon'_{OMe} + E_{p\text{-}OEt} + \varepsilon_{HNO_3})/RT$$
$$\log_e(k_3/2Z) = -(\varepsilon'_{OEt} + E_{p\text{-}OMe} + \varepsilon'_{HNO_3})/RT$$

where ($\varepsilon'_{OMe} + E_{p\text{-}OEt}$) is the energy required to activate carbon atom 2, ε'_{OMe} and $E_{p\text{-}OEt}$ representing respectively the effects of the methoxy- and the ethoxy-group. A similar significance attaches to ε'_{OEt} and $E_{p\text{-}OMe}$. ε_{HNO_3} and ε'_{HNO_3} are the energies required to activate the nitric acid molecule in order that it may react with carbon atoms 2 and 3 respectively. Hence

$$\log_e k_3/k_2 = \{(\varepsilon'_{OMe} - \varepsilon'_{OEt}) + (E_{p\text{-}OEt} - E_{p\text{-}OMe}) + (\varepsilon_{HNO_3} - \varepsilon'_{HNO_3})\}/RT \quad (2)$$

No theoretical grounds exist for supposing that there is any simple relation between the values $k_{p\text{-}X}^{OEt}/k_{p\text{-}X}^{OMe}$ and k_3/k_2 determined by equations (1) and (2) respectively.

The nitration in acetic acid of certain quinol ethers of the type p-RO·C_6H_4·OMe has been studied by Robinson and Smith (J., 1926, 392) and by Clarke, Robinson, and Smith (J., 1927, 2647), and the ratios k_3/k_2 have been determined. The values obtained are compared in the following table with the ratios $k_{p\text{-}X}^{OR}/k_{p\text{-}X}^{OMe}$ for the chlorination of ethers p-RO·C_6H_4·X, given in Part IV.

R.	Nitration. k_3/k_2.	Chlorination. $k_{p\text{-}X}^{OR}/k_{p\text{-}X}^{OMe}$.
Et	1·63	1·99
Pr$^{\alpha}$	1·80	2·20
Bu$^{\alpha}$	1·86	2·22
p-NO_2·C_6H_4·CH_2	0·38	0·143

An obvious parallelism exists, and certain simplifying assumptions will now be made in an attempt to connect equations (1) and (2).

The first assumption is that $\varepsilon_{Cl_2} = \varepsilon'_{Cl_2}$ and $\varepsilon_{HNO_3} = \varepsilon'_{HNO_3}$, and the second that in compounds of the type R_1O·C_6H_4·OR_2, the effect of RO in modifying the amount of energy required to activate carbon atom 3 is proportional to its effect on carbon atom 2, [illegible] $E_{p\text{-}OR_1} = n\varepsilon'_{OR_1}$, and that n is a constant independent of R_1 [illegible]

The third assumption is that $m(\varepsilon_{OR_1} - \varepsilon_{OR_2}) = (\varepsilon'_{OR_1} - \varepsilon_{OR_2})$ where m is a constant. Equations (1) and (2) then become

$$\log_e k_{p\text{-}X}^{OEt}/k_{p\text{-}X}^{OMe} = (\varepsilon_{OMe} - \varepsilon_{OEt})/RT_1 \quad . \quad . \quad . \quad (1')$$

$$\log_e k_3/k_2 = \{m(\varepsilon_{OMe} - \varepsilon_{OEt}) - mn(\varepsilon_{OMe} - \varepsilon_{OEt})\}/RT_2 . \quad (2')$$

whence

$$\log_{10} k_{p\text{-}X}^{OEt}/k_{p\text{-}X}^{OMe} = \frac{T_2}{m(1-n)T_1} \log_{10} k_3/k_2 . \quad . \quad . \quad (3)$$

Unfortunately, there is no means of determining either m or n separately, or the product $m(1-n)$. The arbitrary value 0·6278 has been assigned to $m(1-n)$ and the calculation of the proportions of the isomerides formed by the nitration of 4-ethoxy-, 4-propoxy-, and 4-butoxy-anisole at 0°, and of 4-*p*-nitrobenzyloxyanisole at 24° * from the data for chlorination at 20° of the ethers $RO{\cdot}C_6H_4{\cdot}X$ has been carried out by means of (3), and the results are compared with the observed values in Table I. The agreement is fairly satisfactory.

TABLE I.

Nitration of RO⟨⟩OMe.

R.	3-Nitro-derivative, % Found.	Calc.
Et	62·2	61·4
Pr^n	64·3	63·0
Bu^n	65·0	63·1
p-$NO_2{\cdot}C_6H_4{\cdot}CH_2$	27·6	23·1

The existence of additive relationships for the critical increments for the chlorination of ethers of the type *p*-$RO{\cdot}C_6H_4{\cdot}X$ has been demonstrated (Bradfield and Jones, *loc. cit.*), but the above calculations would have rested on a surer foundation if it were also known that similar relationships obtain for the nitration of the ethers *p*-$R_1O{\cdot}C_6H_4{\cdot}OR_2$. A satisfactory kinetic method for studying nitration does not appear to have been developed, but in this particular case, static measurements, *viz.*, the determination of the final ratio of isomerides formed, can be utilised to provide a test, since Holleman's "product rule" may be applied to the data for the nitration of the two compounds *p*-$R_1O{\cdot}C_6H_4{\cdot}OR_2$ and *p*-$R_3O{\cdot}C_6H_4{\cdot}OR_2$ to calculate the ratio of the isomerides formed by

* In the experiments of Robinson and Smith, and of Clarke, Robinson, and Smith (*loc. cit.*), the temperatures were not kept rigidly constant, but these values appear to be approximately the temperatures during the nitrations. Further, the relative proportions of ether : acetic acid : nitric acid were not the same for the nitration of 4-*p*-nitrobenzyloxyanisole as for the other nitrations, so the figures for this ether are not strictly comparable with the others.

nitration of p-$R_1O{\cdot}C_6H_4{\cdot}OR_2$, and agreement between the observed and calculated ratios would indicate the additivity of the energies of activation. For example, from Robinson and Smith's data for 4-ethoxy- and 4-p-nitrobenzyloxy-anisole, the proportion of 2-nitro-compound formed by nitration of 4-p-nitrobenzyloxy-phenetole at 0° is calculated to be 82·2% (compare, however, footnote, p. 3076); there appear, however, to be no data available to test this calculation.

2. *Phase and Steric Factors.*

The isothermal condition $k_{X_1}^{OR_1}/k_{X_2}^{OR_1} = k_{X_1}^{OR_2}/k_{X_2}^{OR_2}$, derived from the experimental results given in Part IV, has been interpreted as indicating additivity of energies of activation for the chlorination of ethers of the type $RO{\cdot}C_6H_4{\cdot}X$, by extending to these reactions the hypothesis that the product of the phase and steric factors is constant. Nevertheless, other equally simple hypotheses would satisfy this condition, and the following analysis (for which the more detailed subdivision of the E-terms is unnecessary) indicates how some of these hypotheses may be differentiated by a measurement of the change of the ratio of the velocity coefficients with temperature.

First Hypothesis.—That the product of the phase and steric factors is the same for different substances of the type RO⬡X, *under the same conditions, the groups* RO *and* X *then contributing additively to the energy of activation.* This is the hypothesis already promulgated. Suitable algebraic manipulation of the expressions for the velocity coefficients (given in Part IV) derived from this hypothesis, gives the relation

$$k_{X_1}^{OR_1}/k_{X_2}^{OR_1} = e^{\{(E_{X_2}-E_{X_1})+(E_{OR_2}-E_{OR_1})\}/RT}$$

whence, for two different temperatures,

$$\log (k_X^{OR_1}/k_{X_2}^{OR_1})_{T_1} = (T_2/T_1)\log(k_{X_1}^{OR_1}/k_{X_2}^{OR_2})_{T_2} \quad . \quad . \quad (4)$$

Second Hypothesis.—That the energy of activation is the same for all compounds of the type under discussion, and that a replacement of R_1 *by* R_2 *alters the product* PS *to* P'S', *whilst a replacement of* X_1 *by* X_2 *brings about an* n*-fold increase or decrease in* PS *or* P'S'. The equations for the velocity coefficients then become

$$k_{X_1}^{OR_1} = 2PSZe^{-E/RT} \qquad k_{X_1}^{OR_2} = 2P'S'Ze^{-E/RT}$$
$$k_{X_2}^{OR_1} = 2nPSZe^{-E/RT} \qquad k_{X_2}^{OR_2} = 2nP'S'Ze^{-E/RT}$$

whence $k_{X_1}^{OR_1}/k_{X_2}^{OR_1} = 1/n = k_{X_1}^{OR_2}/k_{X_2}^{OR_2}$, as required, and

$$(k_{X_1}^{OR_1}/k_{X_2}^{OR_2})_{T_1} = PS/nP'S' = (k_{X_1}^{OR_1}/k_{X_2}^{OR_2})_{T_2} \quad . \quad . \quad (5)$$

Third Hypothesis.—That the energy of activation is determined solely by the nature of the group OR, *replacement of the group* X_1 *by*

X_2 *causing an* n*-fold increase or decrease of the product* PS, *only.* The equations for the velocity coefficients become

$$k_{X_1}^{OR_1} = 2PSZe^{-E_{OR_1}/RT} \qquad k_{X_1}^{OR_2} = 2PSZe^{-E_{OR_2}/RT}$$
$$k_{X_2}^{OR_1} = 2nPSZe^{-E_{OR_1}/RT} \qquad k_{X_2}^{OR_2} = 2nPSZe^{-E_{OR_2}/RT}$$

whence $k_{X_1}^{OR_1}/k_{X_2}^{OR_1} = 1/n = k_{X_1}^{OR_2}/k_{X_2}^{OR_2}$, as required, and $nk_{X_1}^{OR_1}/k_{X_2}^{OR_2} = e^{(E_{OR_2}-E_{OR_1})/RT}$, whence

$$\log (nk_{X_1}^{OR_1}/k_{X_2}^{OR_2})_{T_1} = (T_2/T_1) \log (nk_{X_1}^{OR_1}/k_{X_2}^{OR_2})_{T_2}. \quad . \quad (6)$$

Fourth Hypothesis.—That the energy of activation is determined by the oxygen atom attached to one carbon atom, as modified by the group X, *replacement of* R_1 *by* R_2 *causing an* n*-fold increase or decrease of the product* PS *only.* The equations then become

$$k_{X_1}^{OR_1} = 2PSZe^{-(E_0+E_{X_1})/RT} \qquad k_{X_1}^{OR_2} = 2nPSZe^{-(E_0+E_{X_1})/RT}$$
$$k_{X_2}^{OR_1} = 2PSZe^{-(E_0+E_{X_2})/RT} \qquad k_{X_2}^{OR_2} = 2nPSZe^{-(E_0+E_{X_2})/RT}$$

whence $k_{X_1}^{OR_1}/k_{X_2}^{OR_1} = e^{(E_{X_2}-E_{X_1})/RT} = k_{X_1}^{OR_2}/k_{X_2}^{OR_2}$, as required, and $nk_{X_1}^{OR_1}/k_{X_2}^{OR_2} = e^{(E_{X_2}-E_{X_1})/RT}$, whence

$$\log (nk_{X_1}^{OR_1}/k_{X_2}^{OR_2})_{T_1} = (T_2/T_1) \log (nk_{X_1}^{OR_1}/k_{X_2}^{OR_2})_{T_2}. \quad . \quad (7)$$

A distinction may be drawn between these hypotheses by measuring the ratio $k_{X_1}^{OR_1}/k_{X_2}^{OR_2}$, at different temperatures, and comparing the change in the ratio with temperature with that calculated by means of expressions 4, 5, 6, and 7, respectively. The fineness of this distinction depends on the experimental accuracy, which, unfortunately, for a decisive result requires to be very much greater that is at present attainable, but Table II shows the agreement between the observed values of $k_{CO_2H}^{OMe}/k_{NO_2}^{OEt}$ at 30° and those calculated from the observed values at 20°.

TABLE II.

	$(k_{CO_2H}^{OMe}/k_{NO_2}^{OEt})_{T_1}$.	$(k_{CO_2H}^{OMe}/k_{NO_2}^{OEt})_{T_2}$. Found.	Calc.	Difference.
Hypothesis 1	74·22	68·82	64·42	−4·40
,, 1 ("corrected") ...	66·8	61·93	58·22	−3·71
,, 2	74·22	68·82	74·22	+5·40
,, 3	74·22	68·82	75·94	+7·12
,, 4	74·22	68·82	62·97	−5·85

A possible objection to the above calculation is that the data for anisic acid and for *p*-nitrophenetole, owing to experimental exigencies, do not refer to identical conditions of concentration, and the observed values of the velocity coefficients depend to some extent on the initial concentrations. However, examination of the data indicates that the velocity coefficient for anisic acid would be slightly lower if it were possible to measure it at the same concentration as that to which the data for *p*-nitrophenetole apply, and that this

"correction" would not amount to more than 10% of the value of k. The value calculated by expression (4) for the ratio at 30° has been recalculated on the assumption that the "corrected" values of the velocity coefficients at 20° and 30° are 10% lower than the observed values, and it is seen that the result is but little affected. This calculation also shows that a small *systematic* error throughout the measurements would lead to little difference in the result.

That the solvent is not without effect on the velocity of reaction is shown by Norrish and Smith (this vol., 129), and it is implicit in all the foregoing that it affects these similar reactions to a similar extent, and that the term representing its effect, which should be introduced into the expression for k, cancels out when ratios are taken. This assumption is in some degree justified by a calculation by Norrish and Smith's method, employing their approximations, of the ratio of the number of effective collisions to the number of collisions fulfilling the energy condition for the chlorination of anisic acid, *p*-nitrophenetole, and ω-trichloroacetanilide, and is of the order 10^{-5} in each case. This factor includes, of course, any P or S terms.

Examination of Table II now shows that the first hypothesis is, *at least*, as correct as the others. The purpose of this discussion will have been served if it has been shown that the data considered here, and in Part IV, find a quantitative explanation within the limits of experimental error, by the single assumption that the different rates of entrance of a given substituent at different points in the same molecule or in similar molecules under identical conditions are determined by the differences of the critical energy increments, without invoking phase or steric factors. An extensive test of this hypothesis on the lines indicated has been begun in these laboratories.

3. *Structure and Reactivity.*

From the new data for the chlorination of anilides in 99% acetic acid, it is seen that the value 0·580 for the velocity coefficient of ω-trichloroacetanilide falls into place in the series acetanilide ($k = 62·2$), formanilide ($k = 9·2$), trichloroacetanilide, showing the general parallel between the rate of chlorination of anilides of the type $C_6H_5·NH·CO·R$ and the strength of the acid $R·CO_2H$. On the other hand, *p*-toluenesulphonanilide chlorinates even more rapidly than benzenesulphonanilide.

The effect of replacing the imino-hydrogen atom of acetanilide by a methyl group in reducing the rate of chlorination roughly to one two-thousandth, is striking. An obvious explanation would be that substitution in the acetanilide nucleus proceeds both by a direct route, and by an indirect one involving the intermediate

formation of a chloroamide, the former process being the slower, whilst for methylacetanilide only the direct route is available. For reasons summarised in Part III of this series, the authors regard this explanation as unlikely, and in addition, qualitative observations of solubility and ease of hydrolysis by aqueous acids indicate that the marked difference in properties of these two substances is not confined to speed of chlorination. *N*-Methylation of *p*-toluenesulphonanilide produces a similar but much smaller effect.

A gap in the series of alkyl groups investigated has been filled by a determination of the velocity coefficients for p-*chlorophenyl* iso*butyl ether* and p-iso*butoxybenzoic acid*. The mean value of the ratio $100k_{p\text{-X}}^{\text{OBu}^{\beta}}/k_{p\text{-X}}^{\text{OMe}}=216$ for these ethers is of the expected order of magnitude. No attempt can be made at present to connect quantitatively the reactivity of these compounds with their structure, but it is noteworthy that the results so far obtained find a simple qualitative explanation in terms of the modern theories of benzene substitution developed by Robinson and Ingold (see summary, *Ann. Reports*, 1926 and 1927).

EXPERIMENTAL.

The measurements of the velocity of chlorination of the following anilides and phenolic ethers were carried out by the method already described (Orton and Bradfield, J., 1927, 986; Bradfield and Jones, *loc. cit.*), the medium being purified acetic acid (Orton and Bradfield, J., 1924, **125**, 960; 1927, 983) containing a total of 1 c.c. of water per 100 c.c. of reaction mixture, previously adopted as standard. Since the reproducibility of the observed velocity coefficients has been sufficiently illustrated in the earlier papers, it will suffice to give in tabulated form the mean values of k.

Ether : chlorine : HCl = 0·0225 : 0·0075 : 0·0375 g.-mol./litre.
$k_{30°} = 0·8898$; $k_{20°} = 0·444$; $k_{30°}/k_{20°} = 2·004$.

p-*Nitrophenetole.*

Ether : chlorine : HCl = 0·20 : 0·02 : 0·05 g.-mol./litre.
$k_{30°} = 0·01293$; $k_{20°} = 0·005983$; $k_{30°}/k_{20°} = 2·16$.

p-iso*Butoxybenzoic acid* was prepared from *p*-hydroxybenzoic acid by a modification of Ladenburg and Fitz's method for the alkylation of hydroxybenzoic acids (*Annalen*, 1867, **141**, 254): 19·4 g. (1 mol.) of *p*-hydroxybenzoic acid were dissolved in a solution of 15·8 g. (2 mols.) of potassium hydroxide in the smallest possible quantity of water, and refluxed at 120° for 7 hours with 26 g. (1·1 mols.) of *iso*butyl iodide and 2 c.c. of *iso*butyl alcohol; 10% potassium hydroxide (1 mol.) was then added, and the refluxing continued for another hour to hydrolyse any ester formed. The product was dissolved and suspended in 50 c.c. of water and just acidified with concentrated hydrochloric acid. The precipitated solid was filtered off, repeatedly washed with water until free from hydrochloric acid, and crystallised from acetic acid; m. p. 136·5° (*M*, by titration, 193·4. Calc.: *M*, 194·2).

p-*Chlorophenyl* iso*butyl ether* was prepared from *p*-chlorophenol, sodium, *iso*butyl alcohol, and *iso*butyl iodide by the usual method, and purified by distillation under 3 mm. pressure (bath temp. 95—97°). The form of the apparatus used did not permit of an accurate determination of the b. p., the velocity coefficient itself being taken as the standard of purity, as described in Part IV; $n_D^{25°} = 1·5090$ (Found: Cl, 19·4. $C_{10}H_{13}OCl$ requires Cl, 19·3%).

The authors wish to express their thanks to Prof. K. J. P. Orton, F.R.S., for his continued interest and valuable advice, and to the Royal Society for a grant which partly defrayed the cost of this investigation.

CCCCIV.—*Strychnine and Brucine. Part VII. The Constitution of the Alkaloids discussed in Relation to the Hypothesis that Dinitrostrychol is an* iso-*Quinoline Derivative.*

By Reginald Clifford Fawcett, William Henry Perkin, jun., and Robert Robinson.

In Part I (J., 1910, **97**, 305) of this investigation the chemistry of strychnine and brucine was discussed from the point of view that the alkaloids are at one and the same time derivatives of quinoline and carbazole, and when it became apparent that what we believe to have been the logical development of a structural hypothesis based on these premises could not be accepted, we were compelled to reconsider these fundamental assumptions.

The only thing that need be said about the question of the supposed carbazole nucleus in the bases is that there is definite experimental evidence pointing to the reality of its existence and that profound decompositions of strychnine do give rise to indole and carbazole (compare Clemo, Perkin, and Robinson, Part IV, J., 1927, 1589, on the formation of indole and carbazole from methylstrychnine); the same cannot be claimed for the hypothetical quinoline residue, since no known quinoline derivative has yet been obtained by the degradation or decomposition of strychnine.

In common, we suppose, with most other chemists who have studied these problems, we have regarded the formation of dinitrostrycholcarboxylic acid by the nitration and oxidation of strychnine with nitric acid (Tafel, *Annalen*, 1898, **301**, 336) as a proof of the existence of a quinoline ring in the alkaloid, but it is the purpose of this communication to point out that the proof is by no means a rigid one and that an alternative view may be sustained.

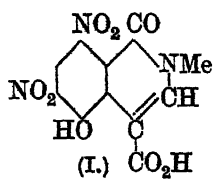
Furthermore, our new suggestion that dinitrostrychol is a dinitrodihydroxy*iso*quinoline has been found to be a starting point for the elaboration of new structural formulæ for strychnine and brucine which are capable of symbolising the behaviour of these bases and their derivatives in a satisfactory manner.

It is well known that strychnine contains two nitrogen atoms, of which one, a-N, is directly attached to an aromatic nucleus with a free para-position and also to a carbonyl group, whereas the other, b-N, is not attached to an aromatic nucleus and is the more basic of the two.

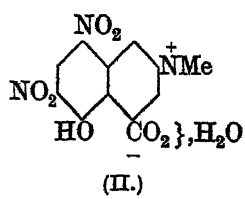
Clear indications that, in methylstrychnine, the methyl group is attached to b-N are given in Part IV (*loc. cit.*).

Now it is plain that, if dinitrostrycholcarboxylic acid is a quinoline derivative, the quinoline ring nitrogen atom must be a-N, and the portion of the molecule that includes b-N has been removed by oxidation; methylstrychnine, on this hypothesis, should also be oxidisable to dinitrostrycholcarboxylic acid.

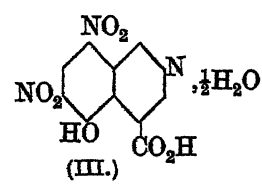
Actually, we find that under the conditions for the production of the acid from strychnine, methylstrychnine gives a different substance (or substances) and the examination of this material, which is not yet complete, has shown that its composition is in fair agreement with the requirements of one of the formulæ



$C_{11}H_7O_8N_3$ (I), $C_{11}H_9O_8N_3$ (II), and $C_{10}H_5O_7N_3,\frac{1}{2}H_2O$ (III).



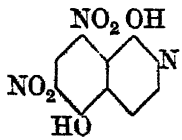
Direct estimation of the methyl attached to nitrogen gave values which were about 30% of that anticipated from I (containing a single NMe group), but as the methyl iodide was liberated with very great difficulty even at 360° it may well have happened that there was considerable reduction to methane.

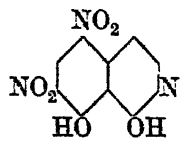


Further distillations gave quite negative results, producing no trace of methyl iodide, so that the presence of NMe in at least a part of the material was qualitatively demonstrated.

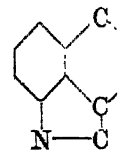
The most probable constitutions corresponding to the above formulæ are represented below and we are actively prosecuting this investigation and examining the oxidation products not only of methylstrychnine, but of other *b-N*-substituted strychnines with nitric acid.

Synthetical work, in relation to the suggested formulæ, is also in progress and we wish to reserve for a short time the experimental development of the subject along the lines suggested by the new conceptions which we advance in this memoir.

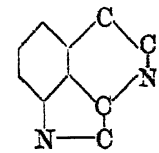




For the purposes of the present discussion we are content to start with the fact that methylstrychnine does not yield dinitrostrycholcarboxylic acid on oxidation, and we deduce from this that the b-NMe group is not situated in the portion of the strychnine molecule that is broken up in the oxidation and that consequently the heterocyclic nitrogen of dinitrostrychol was originally the



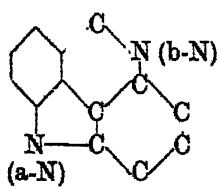
of a strychnine molecule. This is our basic assumption and we think it a sufficiently reasonable one to make it worth while to follow up the consequences. The sequel we believe to be an almost inevitable outcome of this view, but even if the latter proves to be incorrect, several of the suggestions made below can be incorporated in modified strychnine and brucine formulæ and would thus retain some value. If the ring-nitrogen of dinitrostrychol is the b-N of strychnine, then dinitrostrychol must be a dinitrodihydroxy*iso*-quinoline, since b-N cannot be attached to the aromatic nucleus.* In that case a consideration of the fate of the a-N which was attached to the benzene nucleus suggests that the place of a-N is taken by hydroxyl, and on this basis the formulæ (IV) and (V) are feasible as representations of dinitrostrychol.

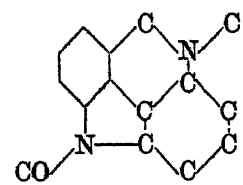


(IV.)

(V.)

(VI.)



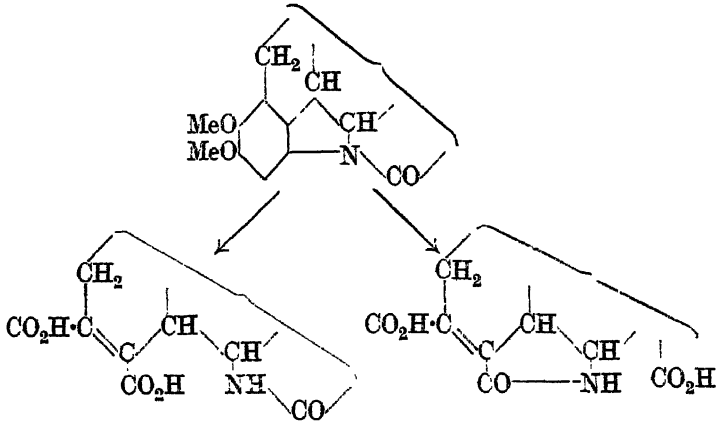


(VII.)

In view of the frequently observed degradation of strychnine to indole derivatives, (IV) and (V) point to the skeletons (VI) and (VII), respectively, as part of the strychnine molecule.

Of these (VI) seems preferable, for it allows the carbazole skeleton to be introduced in a natural manner and we arrive at the conclusion that (VIII) is a ring system of strychnine. This can be expanded to (IX) in view of the tertiary basic character of b-N and the inclusion of a-N in an acid amide grouping.

(VIII.)



(IX.)

This hypothesis that the benzene nucleus of strychnine bears three substituents must be tested in relation to those degradations in which the benzene nucleus is broken up. No difficulties are encountered in this connexion and, for example, the degradation of brucine to Hanssen's acid, $C_{19}H_{22}O_6N_2$, by way of kakothelin

* Because strychnine, unlike strychnidine, does not exhibit the properties of an alkylated aromatic amine with a free para-position.

(nitrobruciquinone hydrate) can be expressed in full detail, the final result being given by the alternatives.

The degradation can be similarly represented if the methoxy-groups are situated in the alternative position vicinal to the indole nitrogen.

It should be mentioned at this point that the very facile nitration of strychnine to dinitrostrychnine hydrate has always appeared to us to require some special explanation.

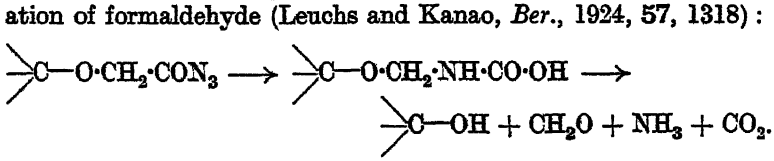
Conceivably the formation of a phenol by rupture of the bond between the aromatic nucleus and a-N occurs at an early stage and both dinitrostrychnine hydrate and nitrobrucine hydrate may be nitrophenolic substances.

In order to make further progress it is necessary to consider the important series of degradations of strychnine and brucine that were carried out by Leuchs and his collaborators (Leuchs, *Ber.*, 1908, **41**, 1711; Leuchs and Schneider, *Ber.*, 1908, **41**, 4393; 1909, **42**, 2494; Leuchs and Weber, *ibid.*, p. 3703; Leuchs and Reich, *Ber.*, 1910, **43**, 2417; Leuchs and Brewster, *Ber.*, 1912, **45**, 201; Leuchs and Peirce, *ibid.*, pp. 2653, 3412; Leuchs and Rauch, *Ber.*, 1914, **47**, 370; Leuchs, *ibid.*, p. 536; Leuchs and Schwaebel, *Ber.*, 1914, **47**, 1552; 1915, **48**, 1009; Leuchs and Bendixsohn, *Ber.*, 1919, **52**, 1443; Leuchs and Ritter, *ibid.*, p. 1583; Leuchs, Hellriegel, and Heering, *Ber.*, 1921, **54**, 2177; Leuchs, Grüss, and Heering, *Ber.*, 1922, **54**, 3729; Leuchs and Nitschke, *ibid.*, p. 3738; Leuchs, Gladkorn, and Hellriegel, *Ber.*, 1923, **56**, 2472).

We offer a new interpretation of these results.

On oxidation with potassium permanganate in acetone solution brucine, $C_{23}H_{26}O_4N_2$, yields the keto-acid brucinonic acid, $C_{23}H_{24}O_8N_2$, and the secondary alcoholic dihydrobrucinonic acid,

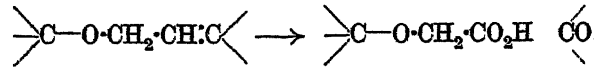
$C_{23}H_{26}O_8N_2$. A stereoisomeride of the latter, namely, brucinolic acid, is obtained by the reduction of brucinonic acid with sodium amalgam.



When brucinolic acid is heated with aqueous potassium hydroxide it yields the neutral brucinolone, $C_{21}H_{22}O_5N_2$, and glycollic acid:

$$C_{23}H_{26}O_8N_2 = C_{21}H_{22}O_5N_2 + C_2H_4O_3.$$

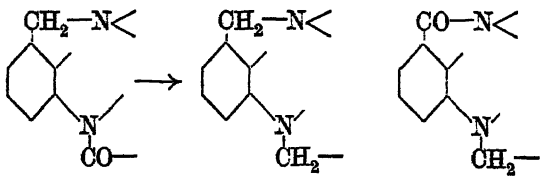
There is no evidence that brucinonic acid is other than a monocarboxylic acid, although a second carboxyl appears to be latent in an *N*-CO group; moreover, the formation of *N*-CO linkages in dilute alkaline solution from >NH and $-CO_2H$ seems improbable. Therefore, by far the simplest and most acceptable view of the loss of glycollic acid is that represented by the scheme:



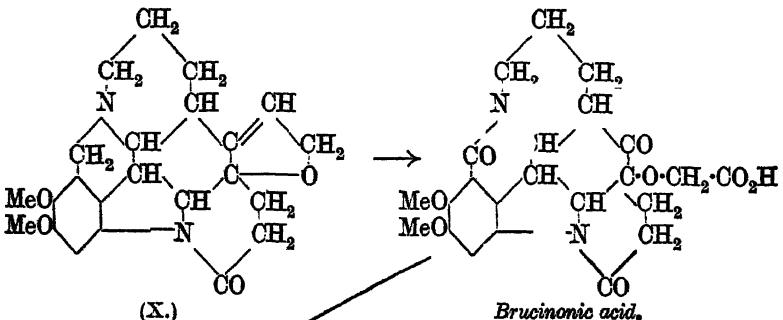
This is supported by the facts that (1) brucinolone contains an ethylene linkage not contained in brucinolic acid, and (2) the acid azide derived from dihydrobrucinonic acid decomposes with formation of formaldehyde (Leuchs and Kanao, *Ber.*, 1924, **57**, 1318):

We need no more than this to show that strychnine and brucine contain cyclic ether oxygen and since the alkaloids also contain one double bond (compare Part VI, Oxford, Perkin, and Robinson, J., 1927, 2389) the complete nuclear system must be elaborated from (IX) by the inclusion of three more rings.

Further, since the double bond is the point of attack of the oxidising agent, a part of the changes involved in the formation of brucinonic acid must be due to the fission



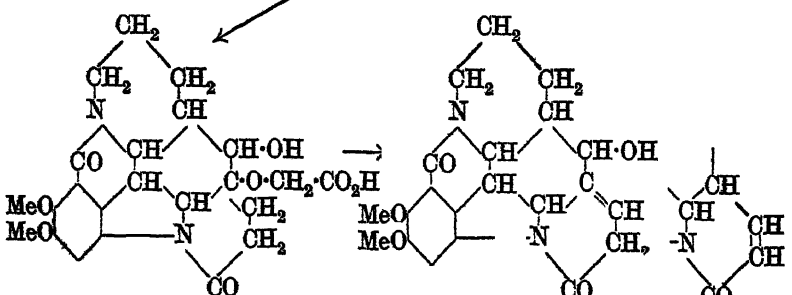
This adds 3O and in some other part of the molecule we must add O and subtract 2H; it is clear that this must be due to the conversion of $-CH_2-N$ (b) into $-CO-N$ (b), because otherwise there is nothing to account for the neutral character of brucinolone.



A formula derived from (IX) will include a methylene group which should, on grounds of analogy, be readily oxidised to carbonyl, because it is well known that the carbon atom numbered 1 in the reduced isoquinoline ring exhibits a marked susceptibility to oxidising agents.

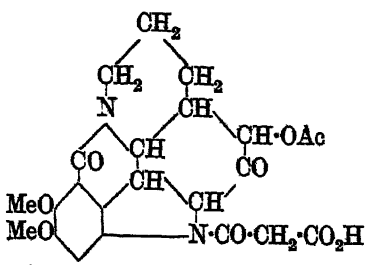
Furthermore, in the course of experiments on the reduction

products of strychnine, a substance has been isolated which appears to be a kind of *epi*strychnine, produced in accordance with the scheme :

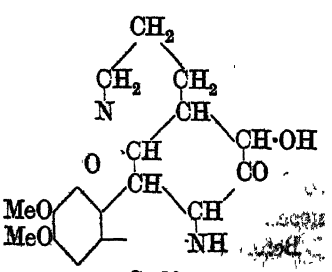


It is hoped that an account of this work will shortly be submitted to the Society.

(X.)



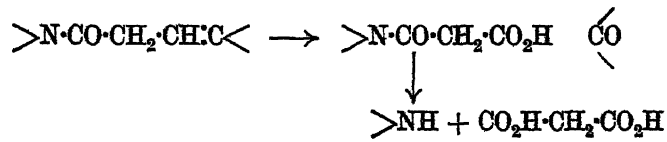
Brucinonic acid.



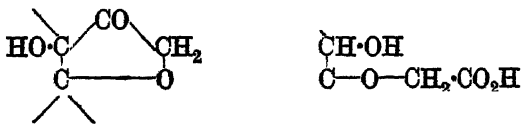
Dihydrobrucinonic and Brucinolic acids.

(*a*) *Brucinolones.*

(*b*)



Acetylbrucinolonic acid.



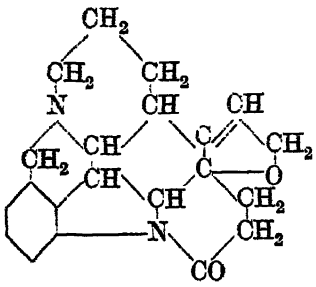
Curbine.

The further degradation of brucinolone to curbine has already been interpreted by Leuchs by means of the scheme:

The elaboration of (IX) so as to accommodate these results can be effected in various ways, and we have considered many alternatives; of these we prefer that, shown below, arising from the postulation of the constitution (X) for brucine.

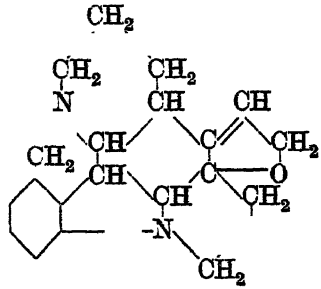
The formation of dihydrobrucinonic acid by the direct oxidation of brucine is, on every view, a curious result; it may be due to the hydrolytic fission:

Some examples of the application of the expression (X) and the analogous strychnine formula (XI) to the explanation of the chemistry of the reduction products are represented in the annexed scheme.



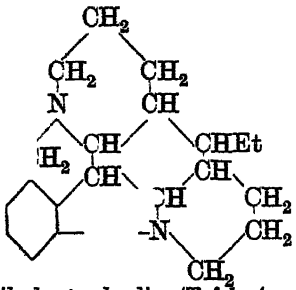
These transformations, described in Part IV (Clemo, Perkin, and Robinson, J., 1927, 1589), take a more normal course at the stage (XII) ⟶ (XIII), when the double bond in (XII) is saturated, the original ring system being reproduced.

Strychnidone (XIV) is here represented as a β-hydroxy-ketone, and the disemicarbazone described in Part IV is then in all probability a semicarbazido-semicarbazone and belongs to a recognised type of αβ-unsaturated ketone derivatives.

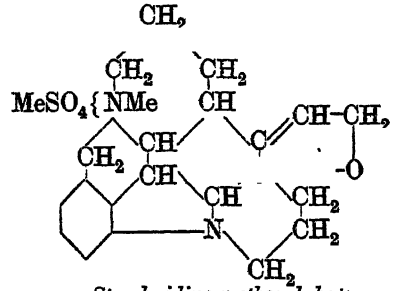


The formulæ for tetrahydrostrychnine and the products of catalytic reduction of strychnine derivatives (compare Part VI, *loc. cit.*) follow automatically, but it must be confessed that we have no very satisfactory explanation of the existence of *iso*strychnine and dihydro*iso*strychnine to put forward.

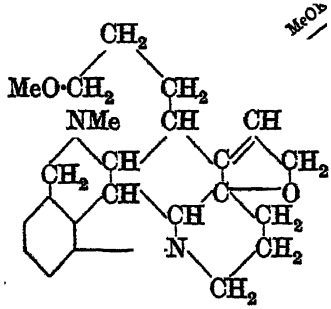
The ether oxygen appears to become hydroxylic and it is therefore possible that the formation of *iso*strychnine involves an intramolecular transfer of hydrogen and that the C–O–C group is reduced to $\rangle$CH HO·C$\langle$; perhaps the dihydroindole group provides the necessary hydrogen atoms.



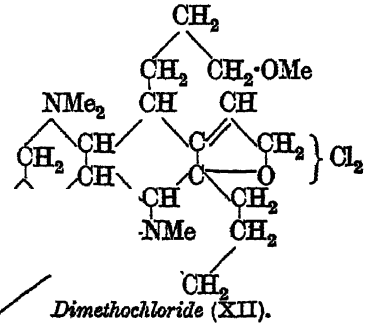
Before considering the permissible modifications of the structures



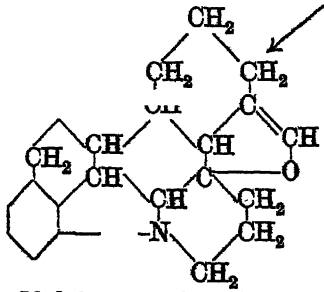
(XI.)



Strychnidine.



Dihydrostrychnoline (Tafel, *Annalen*, 1898, **301**, 324, 326).



Strychnidine methosulphate.

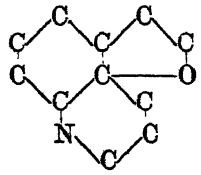
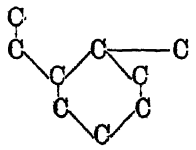
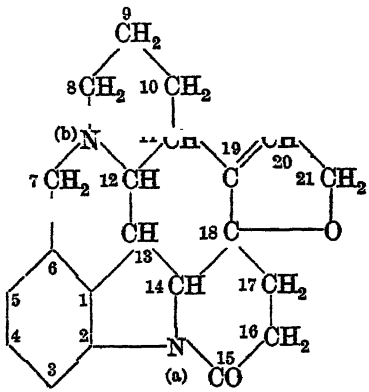
Dimethochloride (XII).





Methyl-ψ-strychnidine (XIII).



Strychnidone (XIV).

(X) and (XI) it may be noted that the assumed ring system (XV) is a heterocyclic analogue of that (XVI) occurring in cholesterol.

(XV.) 

 (XVI.)

A still more significant coincidence is that the formula (XI) contains three straight chains of seven carbon atoms and all are terminally attached to nitrogen. These chains serve as the basis for the numbering given below and allow us to regard strychnine as the reduction and condensation product of a cyanogenetic glucoside which would, of course, contain the C_6–C–N group.

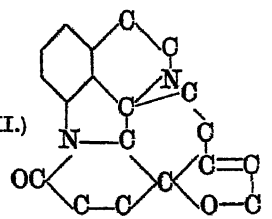
The chief modifications of the formula (XI) that could be made appear to be the following, and various combinations of these are obviously possible. We have selected a definite formula for purposes of illustration only and the alternatives are not excluded.

(1) Some of the rings may be bridged-rings. For instance, C-10 may be attached, not to C-11, but to C-13 or C-14, preserving in the latter case the three chains of seven carbon atoms. This view is a serious alternative, for it has the advantage that the hydroindole nucleus is blocked and the formation of carbazole involves less stripping off of external groups.

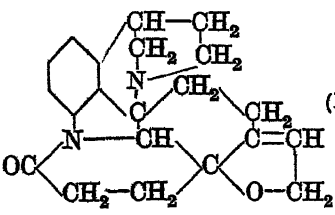
C-20 also might be attached to some other carbon atom, for example, C-10. This spoils the three chains of seven carbon atoms but gives a curbine formula not containing the group –CO·CH(OH)–.

(2) The carbon atoms 8, 9, and 10 may take the *iso*-form $-CH_2\cdot CHMe-$. In certain cases this is also possible for 15, 16, 17.

(3) The ring oxygen may be attached to C-11, giving different but analogous formulæ for the Leuchs series of degradation products. This alternative requires that C-8 should be the point of oxidation, $-N-CH_2- \longrightarrow -N-CO-$. The attachment of the ring oxygen to C-17 we consider to be improbable in view of the alkaline decomposition of brucinolic acid which gives, as the primary product, brucinolone-a containing the group $-N\cdot CO\cdot CH_2\cdot CH{=}\overset{|}{C}-$, and this is further transformed by alkali into brucinolone-b characterised by the group $-N\cdot CO\cdot CH{=}CH-\overset{|}{C}H-$ (Leuchs and co-workers, *loc. cit.*). We are of the opinion that a group $-N\cdot CO\cdot CH_2\cdot \underset{O\cdot CH_2\cdot CO_2H}{\overset{|}{C}H}-\overset{|}{C}H-$ would give, in the first instance, the αβ-unsaturated substance on fission in alkaline solution.



The view which we have put forward in relation to strychnidone (XIV) is also untenable if the ring oxygen is attached to C-17.



(4) The work of Lions, Perkin, and Robinson (Part III, J., 1925, **127**, 1158) showed that the methoxyls in brucine are situated in the ortho-position to one another and that there can be no free position para to either of the methoxyls. Thus the methoxyls may occupy the positions 4 and 5 as in (X) or positions 3 and 4.

(5) Going back to the alternative (VII), which was temporarily set aside in view of the less bizarre character of the formulæ based on (VI), the inclusion of a carbazole skeleton and the groups necessary to express the Leuchs degradations gives (XVII) or a very similar skeleton. Two carbon atoms must be added; one of them is required to make b-N tertiary, and the other to provide the carboxyl group of dinitrostrycholcarboxylic acid. This leads to the strychnine formula (XVIII) or bridged-ring alternatives.

The decision between structures based on (VI) and those based on (VII) can best be made by a synthesis of dinitrostrychol, which we are attempting at the present time.

(XVII.)

(XVIII.)

Concurrently with the investigations referred to above, we are continuing our study of the reduction products of strychnine and brucine and have been for some time engaged in the careful examination of the crystalline substances formed when the methosulphates

of strychnine and strychnidine are submitted to the action of sodium amalgam. One of the rings can be readily opened in this way and we wish to reserve for a short time the investigation of this interesting decomposition.

NOTES.

The Acetylation of Diethylene Oxide. By MORNA MACLEOD.

EXPERIMENTS carried out by Knoevenagel (*Annalen*, 1913, **402**, 133) on the interaction of acetic anhydride with various ethers in the presence of anhydrous ferric chloride suggested a method by which the presence of two oxide rings in ngaione (McDowall, J., 1925, **127**, 2200) might be confirmed and investigated. Some tests were therefore made with compounds of known constitution.

Knoevenagel's results for cineole were verified, and the reaction was then applied to diethylene oxide. Besides some unchanged diethylene oxide, small quantities of glycol diacetate and ββ′-*diacetoxyethyl ether* were obtained.

$$2\begin{matrix}CH_2\cdot OAc\\CH_2\cdot OAc\end{matrix} \xleftarrow{2Ac_2O} O\begin{matrix}CH_2\cdot CH_2\\CH_2\cdot CH_2\end{matrix}O \xrightarrow{Ac_2O} O\begin{matrix}CH_2\cdot CH_2\cdot OAc\\CH_2\cdot CH_2\cdot OAc\end{matrix}$$

The latter compound was a moderately viscous, sweet-smelling oil, b. p. 110—135°/16 mm., d_{20}^{20} 1·123, n_D^{20} 1·4348, whence $[R_L]_D$ = 44·12 (Found: C, 50·9; H, 7·3; sap. value, 582. $C_8H_{14}O_5$ requires C, 50·5; H, 7·4%; $[R_L]_D$, 43·98; sap. value, 589).—THE RALPH FORSTER LABORATORIES OF ORGANIC CHEMISTRY, UNIVERSITY COLLEGE, LONDON. [*Received, October 8th*, 1928.]

The Nitration of o-*Bromoacetanilide.* By CHARLES STANLEY GIBSON and JOHN DOBNEY ANDREW JOHNSON.

THE nitration of *o*-bromoacetanilide proceeds readily according to the method of Franzen and Engel (*J. pr. Chem.*, 1921, **102**, 188), but their description of the separation of the isomeric mononitration products is a little confused. They agitated the finely divided crude nitration product with ice-cold "Witt–Utermann solution" (75 g. of potassium hydroxide, 475 c.c. of water, 100 c.c. of ethyl alcohol), 2-Bromo-6-nitroacetanilide was said to dissolve, and 2-bromo-4-nitroacetanilide was left undissolved. It was further stated that when the solution of the 6-nitro-compound was kept at room

temperature for 24 hours, hydrolysis took place and 2-bromo-6-nitroaniline was precipitated.

It has now been found that the crude nitration product is almost completely soluble in the "Witt–Utermann solution," only 2% remaining undissolved. The filtrate becomes turbid and after 15—20 minutes a yellow solid begins to separate, precipitation being complete after 24 hours. This crude product had m. p. 94—98° and after crystallisation from benzene–ligroin (b. p. 60—80°) had m. p. 104°, the melting point of 2-bromo-4-nitroaniline. The nature of this compound was further verified by bromination in acetic acid solution, the dibromonitroaniline, m. p. 206°, obtained being identical with 2 : 6-dibromo-4-nitroaniline prepared by the bromination of *p*-nitroaniline.

The filtrate remaining after the separation of the 2-bromo-4-nitroaniline from the "Witt–Utermann solution," on treatment with glacial acetic acid gave a precipitate of a substance which crystallised from methyl alcohol in long needles, m. p. 193°, the melting point of 2-bromo-6-nitroacetanilide. On boiling a solution of this substance (5 g.) in alcohol (24 c.c.) and hydrochloric acid (12 c.c.) for 3 hours, hydrolysis took place, the 2-bromo-6-nitroaniline having m. p. 74—75° after recrystallisation from ligroin (b. p. 40—60°) (compare Meldola and Streatfeild, J., 1898, **73**, 686, who give m. p. 73—74°).

Chattaway, Orton, and Evans (*Ber.*, 1900, **33**, 3061) obtained 2-bromo-4-nitroacetanilide (m. p. 129°) by the action of acetyl chloride in acetic acid on 2-bromo-4-nitroaniline. Körner (*Atti R. Accad. Lincei*, 1914, **22**, i, 825), using acetic anhydride, obtained a monoacetyl derivative, m. p. 114°, and a diacetyl derivative, m. p. 132°. On repeating the work of the former authors, it was found that the monoacetyl derivative is indeed formed and has m. p. 132—133° (Found: N, 11·1. Calc.: N, 10·8%. The diacetyl derivative requires N, 9·3%). This monoacetyl derivative, contrary to the statement of Franzen and Engel, is readily soluble in "Witt–Utermann solution."

All the *o*-bromoacetanilide used in the work was prepared from *o*-bromoaniline, b. p. 110·5°/19 mm. From 204 g. of pure *o*-bromoacetanilide, 66 g. of pure 2-bromo-4-nitroaniline and 80 g. of pure 2-bromo-6-nitroacetanilide were obtained.—GUY'S HOSPITAL MEDICAL SCHOOL (UNIVERSITY OF LONDON), S.E. 1. [*Received, September 17th*, 1928.]

CCCCV.—*The Alkaloids of Some Indian Aconites. Part II. Pseudaconitine.*

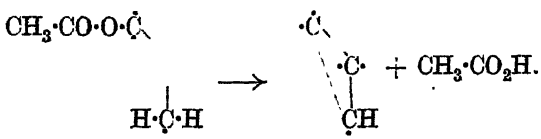
By THOMAS MARVEL SHARP.

MOST of the species of *Aconitum* which have been examined chemically have been found to contain alkaloids, each species in general yielding a different alkaloid; pseudaconitine has, however, been obtained from two species, *Aconitum deinorrhizum* and *A. Balfourii*. The alkaloids may be subdivided into (*a*) poisonous alkaloids of the aconitine type and (*b*) relatively non-toxic alkaloids of the atisine type. With the exception of lycaconitine (Schulze and Bierling, *Arch. Pharm.*, 1913, **251**, 8) and lappaconitine (Schulze and Ulfert, *ibid.*, 1922, **260**, 230; Weidemann, *Arch. Exp. Path. Pharm.*, 1922, **95**, 166) the alkaloids of the former type (*a*) are similar in that they are all diacyl esters of other bases which are generically called "aconines," *e.g.*, aconine, japaconine, pseudaconine, bikhaconine; in each of these cases one of the groups is acetyl. Aconitine, the best known of the alkaloids, is derived from a European species, *A. Napellus*, and is acetylbenzoylaconine. Two interesting reactions of this alkaloid have been described by Dunstan and collaborators (Dunstan, Tickle, and Jackson, P., 1898, **14**, 159; Dunstan and Carr, J., 1894, **65**, 176). When aconitine is heated in a sealed tube with methyl alcohol, the acetyl group is replaced by a methyl group with the formation of methylbenzoylaconine. The second reaction is also concerned with the acetyl group: when the dry base is heated slightly above its melting point, one molecule of acetic acid is split off and a new base, pyraconitine, is formed. The latter reaction has been shown to be general for those aconitine alkaloids which contain an acetyl group (Dunstan and Carr, *loc. cit.*; J., 1897, **71**, 358; Dunstan and Read, J., 1900, **77**, 60; Dunstan and Andrews, J., 1905, **87**, 1631, 1648; Majima and Suginomé, *Ber.*, 1924, **57**, 1466; Majima and Morio, *ibid.*, p. 1472) and has been studied in some detail in the cases of aconitine and japaconitine by Schulze and Liebner (*Arch. Pharm.*, 1913, **251**, 453; 1916, **254**, 567).

Formula (I) summarises what is at present known regarding the constitution of pseudaconitine.

(I.) $C_{19}H_{21}\begin{cases}(O\cdot CH_3)_4(CH\cdot OH)(N\cdot CH_3)(OH)(O\cdot CO\cdot CH_3)\\ O\cdot CO\cdot C_6H_3(O\cdot CH_3)_2\end{cases}$

It was thought that a careful study of the two reactions recorded by Dunstan and collaborators might throw some light on the relative positions of the groups present in pseudaconitine, and that



pyropseudaconitine might contain some weakened link, which would be a useful point of attack by oxidation or other degradation process, pseudaconitine having been shown in the previous paper (Henry and Sharp, this vol., p. 1105) to be very resistant to oxidation.

It is now found that when pseudaconitine is heated in a sealed tube with methyl alcohol, the acetyl group is replaced by methyl, and that the same reaction takes place—but more slowly—when the base is boiled under reflux with the alcohol. A similar reaction also takes place when tetra-acetylpseudaconine is treated with either methyl or ethyl alcohol, one and only one of the acetyl groups being replaced by the methyl or ethyl group, the latter being introduced at a much slower rate. It is evident, therefore, that there is some group present in a particular relation to this acetyl group which facilitates the replacement. In an attempt to find such a group, a number of acetyl derivatives of comparatively simple constitution have been prepared and treated with methyl alcohol in this manner, but so far without success. The acetyl group or groups in acetylphenol, diacetylpyrocatechol, diacetylresorcinol, diacetylquinol, triacetylpyrogallol, acetylsalicylic acid, acetylpropenylguaiacol, acetyleugenol, acetyl*iso*eugenol, acetyl*cyclo*hexanol, penta-acetyl-*l*-quercitol, penta-acetylmethylinositol, and hexa-acetylmannitol are not replaced in this way.

As stated by Dunstan and Carr (*loc. cit.*), when pseudaconitine is heated above its melting point it loses acetic acid with the formation of pyropseudaconitine, which has now been crystallised. The operation is best carried out in a vacuum, but it is possible that the reaction takes place in more than one way, since a portion of the product could not be induced to crystallise.

The loss of acetic acid can take place in three ways: (*a*) by the removal of acetic acid between the acetyl group and a hydroxyl, in which case an ether linkage will be formed; (*b*) by the removal of a hydrogen atom from a neighbouring carbon atom, in which case a double bond will be formed; (*c*) by the removal of a hydrogen atom from a carbon atom in a remote position, with the formation of a bridged linkage. Pseudaconitine was shown in the previous paper (*loc. cit.*) by indirect means to contain two hydroxyl groups; this is now directly proved by the formation of a diacetyl derivative. In case (*a*), therefore, only a monoacetyl derivative of pyropseudaconitine should be formed; in cases (*b*) and (*c*) pyropseudaconitine should yield a diacetyl derivative, and (*b*) would probably be readily reduced by hydrogen in the presence of an active catalyst. If case (*a*) holds, tetra-acetylpseudaconine, which does not contain a free hydroxyl group, should not lose acetic acid on heating [illegible]

it does so behave, the aconine obtained from it on hydrolysis should be different from that obtained by the hydrolysis of pyropseudaconitine. As a fact, tetra-acetylpseudaconine on heating does lose one molecule of acetic acid with the formation of triacetylpyropseudaconine, and this on hydrolysis furnishes pyropseudaconine identical with the base obtained on hydrolysis of pyropseudaconitine. Moreover, on acetylation, pyropseudaconitine yields a compound which contains three acetyl groups but has only five methoxyl groups, whereas pyropseudaconitine has six. Analysis leaves no doubt that the substance has been formed by the acetylation of the two hydroxyl groups and the replacement of one methyl by an acetyl group. The aconine obtained on hydrolysis of this substance is quite different from that obtained from pyropseudaconitine and triacetylpyropseudaconine in that all attempts at crystallisation have failed, whereas the base from the other sources crystallises readily. It is difficult to chose between (*b*) and (*c*), but, as triacetylpyropseudaconine resists catalytic reduction by hydrogen, it is highly probable that the loss of acetic acid takes place between the acetyl group and a hydrogen atom attached to a remote carbon atom, and therefore that a bridged linkage is formed. This would cause the carbon atom in question to become asymmetric so long as it formed part of a saturated chain or ring, according to some such scheme as the following:

This view receives support from the specific rotations of pyropseudaconitine and triacetylpyropseudaconine, which are much greater than those of the bases from which they are derived.

It is interesting to compare these results with those obtained by Schulze and Liebner (1916, *loc. cit.*) with aconitine. According to these authors, aconitine, which contains three hydroxyl groups, on heating yields pyraconitine by the loss of acetic acid between the acetyl and a hydroxyl group, with the formation of an ether. The evidence for this is rather slender, being based on the analysis of the gold salt of the acetyl derivative of pyraconitine, which agrees with that of a diacetyl derivative, whereas a triacetyl derivative would be formed if all the hydroxyls were unchanged by the pyrogenous decomposition. A direct estimation of the acetyl groups in the acetyl derivative did not give a conclusive result, owing no doubt to the too drastic conditions employed. If Schulze and Liebner's conclusions are correct, they would indicate a considerable

difference in the form of combination of the groups concerned in aconitine and pseudaconitine.

The two rather unusual reactions recorded above, *viz.*, the replacement of acetyl by methyl by boiling pseudaconitine with methyl alcohol, and the replacement of a methyl by acetyl in pyropseudaconitine—a replacement which does not occur when triacetylpyropseudaconitine is treated similarly with acetic anhydride—emphasise the necessity for the determination of methoxyl groups and acetyl groups in any investigation of the aconitine alkaloids. The only similar case which has been found in the literature is the replacement of one ethyl group in diethylacetal by an acetyl group (Claisen, *Ber.*, 1898, **31**, 1018); there is no evidence, however, that an acetal group occurs in pseudaconitine.

Although diacetylpseudaconitine is readily formed, it has only been found possible to prepare a monobenzoyl derivative.

Experimental.

Pyropseudaconitine.—Dry pseudaconitine (5·1408 g.) was heated at 220° for 10 minutes in a good vacuum in a tube connected through a Volhard trap, cooled with ice and salt, to a pump. It lost 0·4286 g. (8·34%), and 0·4222 g. of acetic acid was collected in the Volhard trap (calc. for the loss of 1 mol. of acetic acid, 8·7%). The acid crystallised at once on the addition of a trace of solid acetic acid, and without purification melted at 15°. The residue in the reaction tube consisted of a brittle, light reddish-brown resin, which was powdered, dissolved in 1% hydrochloric acid, made alkaline with ammonia, and extracted with ether. After drying over sodium sulphate, the ether left on evaporation 4·65 g. of a pale yellow varnish, which was dissolved in 50% aqueous alcohol; the substance was then obtained in bundles of colourless, stout needles (3·37 g.), m. p. 132—135°, $[\alpha]_D^{16°}$ + 175·2° (c = 1·154 in alcohol). Pyropseudaconitine is very soluble in the usual organic solvents and could only be crystallised from 50% alcohol (Found: C, 65·0; H, 7·7; OMe, 28·5; NMe, 3·1. Calc. for $C_{34}H_{47}O_{10}N$: C, 64·8; H, 7·5; 6OMe, 29·6; NMe, 4·6%). The remainder of the reaction product was only obtained as an amorphous, colourless solid and may have been formed according to one of the alternative reactions outlined in the introduction (p. 3095).

Pyropseudaconitine does not react with methyl iodide.

Hydrolysis. A solution of pyropseudaconitine (4·7 g.) in alcohol (75 c.c.) was treated with potassium hydroxide (4·7 c.c. of 50% aqueous solution) and kept for 24 hours. It was then acidified with sulphuric acid, filtered from potassium sulphate, and diluted with water (50 c.c.) and the alcohol was removed by distillation

under reduced pressure on a water-bath. On cooling, a white, crystalline solid (1·25 g.) separated; extraction with ether furnished a further 0·1 g. of the same substance, m. p. 187°, which was identified as veratric acid by mixed melting-point determination. The aqueous mother-liquor was made alkaline with sodium carbonate solution and extracted with chloroform. After drying over sodium sulphate, the chloroform yielded on evaporation a light brown varnish (3·2 g.), which was dissolved in ether, filtered from a little amorphous substance, evaporated to dryness under reduced pressure, and redissolved in dry ether; it then suddenly crystallised in needles. After recrystallisation from dry ether, the substance was obtained in aggregates of prismatic, faintly brown needles, m. p. 172°, $[\alpha]_D + 227{\cdot}5°$ ($c = 1{\cdot}217$ in alcohol) (Found on substance dried at 110° in a vacuum: C, 64·4; H, 8·6; OMe, 26·5; NMe, 4·25. $C_{25}H_{39}O_7N$ requires C, 64·5; H, 8·45; 4OMe, 26·7; NMe, 6·2%). *Pyropseudaconine* is very soluble in organic solvents, and in water, forming an alkaline solution; an aqueous solution acidified with sulphuric acid gave only a faint white precipitate with Mayer's reagent, and a slight, brown, sticky precipitate with iodine in potassium iodide; tannic acid, sodium perchlorate, picric acid, and platinic chloride do not produce precipitates. Gold chloride gives a slight yellow cloudiness.

Acetylation. Pyropseudaconitine (3·6 g.) was boiled under reflux for 1½ hours with acetic anhydride (15 c.c.). The solution was evaporated to dryness, and the residue dissolved in alcohol and again evaporated to dryness, the evaporation with alcohol being repeated three times. The product was then again dissolved in hot alcohol; on cooling, the compound separated in colourless prisms, m. p. 228°, $[\alpha]_D^{19°} + 28{\cdot}4°$ ($c = 0{\cdot}537$ in chloroform) [Found in substance dried at 120° in a vacuum: C, 63·4, 63·3; H, 7·2, 7·05; OMe, 21·2; NMe, 2·3; acetic acid (see below), 23·4. $C_{39}H_{51}O_{13}N$ requires C, 63·1; H, 6·9; 5OMe, 20·9; NMe, 3·9; $3CH_3{\cdot}CO_2H$, 24·3%]. It is evident, therefore, that the substance is *triacetyldemethylpyropseudaconitine*, formed by the replacement of a methyl by an acetyl group and the acetylation of two hydroxyl groups.

Hydrolysis of Triacetyldemethylpyropseudaconitine.—Dry, finely powdered triacetyldemethylpyropseudaconitine (1·9699 g.) was suspended in 150 c.c. of neutral alcohol, potassium hydroxide (2 c.c. of 50% aqueous solution) added, and the mixture kept at room temperature for 24 hours. The clear solution was then exactly neutralised with sulphuric acid, sufficient water added to dissolve the precipitated potassium sulphate, and the alcohol removed in a current of steam generated from freshly-boiled distilled water free from carbon dioxide. The solution was acidified with sulphuric

acid and steam-distilled, and the distillate titrated with *N*/2-sodium hydroxide and phenolphthalein. The volatile acid required 14·7 c.c. of 0·5218*N*-sodium hydroxide, equivalent to 23·36% of acetic acid, which was identified by analysis of the silver salt (Found: Ag, 63·7. Calc.: Ag, 64·7%). The residue from the steam distillation was extracted with ether (which furnished veratric acid, identified as described above), made alkaline with sodium carbonate, and extracted with chloroform. The chloroform after drying gave a colourless varnish (1·4 g.) on evaporation. This was dissolved in hot dry ether: the filtered solution slowly deposited a white, amorphous solid. On heating, the compound effervesces at about 90°. It has only been obtained in an amorphous condition, even after the addition of a trace of crystalline pyropseudaconine. Like pyropseudaconine, it gives only faint precipitates with Mayer's reagent and iodine in potassium iodide solution and does not form crystalline salts or yield precipitates with such reagents as sodium perchlorate, picric acid, platinic chloride, and tannic acid. It is very soluble in water, forming an alkaline solution, and in most organic solvents. From hot benzene it separates in an amorphous condition. A determination of methoxyl in a specimen which had separated from benzene and had been dried first in a desiccator, then at 70°, and finally at 90° in a vacuum, supports the view that the compound is a *demethylpyropseudaconine* (Found: OMe, 18·9; NMe, 3·55. $C_{24}H_{37}O_7N$ requires 3OMe, 20·6; NMe, 6·4%). This is as near to the theoretical figure as is to be expected on amorphous material.

Triacetylpyropseudaconine.—Tetra-acetylpseudaconine (5·6332 g.) (Henry and Sharp, this vol., p. 1112) was heated at 240° for 10 minutes in the manner described for the preparation of pyropseudaconitine (p. 3097). A vigorous evolution of acetic acid took place, the loss in weight being 0·5336 g. (9·47%. Calc. for 1 mol. of acetic acid, 9·22%). The residual pale yellow resin was powdered, dissolved in 1% hydrochloric acid, and made alkaline with ammonia, and the base extracted in ether. The residue left on evaporation of the solvent was dissolved in 50% alcohol; it was then obtained in colourless, six-sided plates (4·68 g.), m. p. 155—158°, $[\alpha]_D$ + 156·4° (c = 1·202 in alcohol), + 156·6° (c = 0·709 in alcohol) (Found: C, 63·05, 63·0; H, 7·7, 7·7; OMe, 20·3; NMe, 3·7; acetic acid, 31·1. $C_{31}H_{45}O_{10}N$ requires C, 62·9; H, 7·7; 4OMe, 21·0; NMe, 4·9; $3CH_3{\cdot}CO_2H$, 30·45%). The base is very soluble in ether when freshly precipitated from a solution of a salt, and is readily soluble in alcohol, benzene, chloroform, and ethyl acetate. It does not yield crystalline salts. The acetyl groups were estimated by hydrolysis with alcoholic potassium hydroxide as described under

triacetyldemethylpyropseudaconitine. The residue from the steam-distillation was cooled, made alkaline with sodium carbonate, and extracted with chloroform. The chloroform on evaporation yielded a pale brown varnish, which, after solution in ether, was obtained in stout, prismatic needles, m. p. 173—174°, $[\alpha]_D$ + 230·1° (c = 1·12 in alcohol). A solution of the base acidified with sulphuric acid gave a faint white precipitate with Mayer's reagent, a slight, brown, pasty precipitate with iodine in potassium iodide solution, and no precipitate with picric acid, tannic acid, sodium perchlorate, or platinic chloride. Auric chloride caused a slight yellow cloudiness. A mixed melting-point determination with pyropseudaconine obtained by the hydrolysis of pyropseudaconitine showed no depression. The products obtained by the hydrolysis of either pyropseudaconitine or triacetylpyropseudaconine are thus identical.

In order to test whether a double bond had been introduced into the molecule in the splitting off of acetic acid, triacetylpyropseudaconine (0·5 g.) was dissolved in alcohol (20 c.c.), and shaken with hydrogen under 3 atmospheres pressure with the addition of an active palladium–barium sulphate catalyst (0·1 g.) for 2 hours; no hydrogen was absorbed. The catalyst was filtered off, the filtrate evaporated to dryness, and the residue dissolved in 50% alcohol; unchanged triacetylpyropseudaconine then crystallised in characteristic six-sided plates, m. p. 155—158° (yield, quantitative).

Action of Heat on Pseudaconine.—It was thought that pseudaconine, on being strongly heated, might lose water with the formation of pyropseudaconine. A quantity of the base crystallised from acetone was therefore placed in a weighing bottle in the apparatus described above and heated at 120—130°. The compound frothed with loss of 1 mol. of acetone, which was collected in water and identified by conversion into iodoform (Found: loss at 120—130°, 10·4. $C_{25}H_{41}O_8N,C_3H_6O$ requires loss, 10·7%). The temperature was raised to 150° and then by successive rises of 10° to 210°, at which temperature the first loss in weight was observed. At this temperature also a ring of varnish collected on the cooler part of the reaction tube and the substance began to darken; it was evidently beginning to distil (with slight decomposition), since pseudaconine was recovered from the heated substance in a yield of 90%.

Veratroylmethylpseudaconine.—Pseudaconitine (5 g.) was heated in a sealed tube at 130° for 6 hours with 35 c.c. of methyl alcohol. The alcohol was removed and the residue was dissolved in 1% hydrochloric acid, made alkaline with sodium carbonate, and extracted with ether. The ether soon began to deposit crystals; it was, however, found convenient to distil the ether and convert

the residue (5 g., not completely dried) into the *hydrobromide*, which separated from water in colourless crystals containing $1H_2O$, m. p. 237—238° (with efferv.), $[\alpha]_D$ + 2·15° (c = 2·09 in water) (Found: loss at 120° in a vacuum, 2·6. $C_{35}H_{51}O_{11}N,HBr,H_2O$ requires loss of $1H_2O$, 2·4%. Found on anhydrous substance: C, 56·3, 56·5; H, 7·5, 6·8; N, 1·9; OMe, 28·75; NMe, 2·55; Br, 11·1. $C_{35}H_{51}O_{11}N,HBr$ requires C, 56·6; H, 7·1; N, 1·9; 7OMe, 29·3; NMe, 3·9; Br, 10·8%). The *base*, prepared from the purified hydrobromide, crystallised from 50% alcohol in colourless prisms, m. p. 206—207°, $[\alpha]_D$ + 29·8° (c = 1·12 in alcohol) (Found on substance dried at 120° in a vacuum: C, 63·7; H, 7·9; OMe, 33·0; NMe, 2·8. $C_{35}H_{51}O_{11}N$ requires C, 63·5; H, 7·8; 7OMe, 32·9; NMe, 4·4%). The *hydrochloride* crystallised from alcohol–ether in hard, hemispherical aggregates of colourless needles, m. p. 249—250° (decomp.), $[\alpha]_D$ − 3·41° (c = 5·43 in water), + 0·38° (c = 2·62 in alcohol) (Found: Cl, 5·1. $C_{35}H_{51}O_{11}N,HCl$ requires Cl, 5·1%).

Acetylation. (a) *Acetic anhydride.* Veratroylmethylpseudaconine (2 g.) was boiled under reflux for an hour with acetic anhydride (10 c.c.). Excess of the reagent was distilled off, the residue dissolved in 1% hydrochloric acid, and sodium perchlorate solution added in excess. The white precipitate was washed well with water and dried in a desiccator (2·2 g.). After crystallisation from absolute alcohol, the *perchlorate* was obtained in stout, colourless needles, m. p. 240—242° (Found on substance dried at 110° in a vacuum: OMe, 26·9; NMe, 2·2. $C_{37}H_{53}O_{12}N,HClO_4$ requires 7OMe, 27·0; NMe, 3·6%). Acetyl groups were estimated in the manner already described (p. 3098), but owing to the sparing solubility of the salt more alcohol was required (300 c.c. for 0·7 g.) and the mixture was kept for 40 hours (Found: acetic acid, 8·5. $C_{37}H_{53}O_{12}N,HClO_4$ requires for 1 mol. of acetic acid, 7·5%). The substance is therefore a *monoacetylveratroylmethylpseudaconine perchlorate*. The mother-liquor from the steam distillation of the acetic acid was extracted with ether, which removed veratric acid (0·17 g.), made alkaline with ammonia, and extracted with chloroform. The chloroform furnished on evaporation a light brown varnish (0·5 g.), which was not obtained crystalline but must have been methylpseudaconine. It was very soluble in water and in most organic solvents and did not give any crystalline salt.

The formation of a monoacetyl derivative was unexpected in view of the fact that pseudaconitine contains two hydroxyl groups, which should have remained intact in the replacement of an acetyl by a methyl group. A diacetyl derivative was, however, obtained by acetylation with acetyl chloride.

(b) *Acetyl chloride.* Veratroylmethylpseudaconine (2·5 g.) was

boiled under reflux for an hour with acetyl chloride (12 c.c.). Excess of the reagent was evaporated, and the residue dissolved in water and made alkaline with ammonia; the white precipitate which formed was washed well with water and dried. After crystallisation from absolute alcohol *diacetylveratroylmethylpseudaconine* was obtained in colourless needles or compact crystals (2·2 g.). Either form melts at 160°, resolidifies after a time, and then remelts at 196°; $[\alpha]_D$ + 18·43° in chloroform (c = 1·248) (Found on substance dried at 120° in a vacuum : OMe, 28·65; NMe, 2·1; acetic acid, 16·5. $C_{39}H_{55}O_{13}N$ requires 7OMe, 29·1; NMe, 3·9; $2CH_3{\cdot}CO_2H$, 16·1%). Methylpseudaconine and veratric acid were recovered from the mother-liquor from the determination of acetyl groups in the manner described under monoacetylveratroylmethylpseudaconine (see above).

Triacetylmethylpseudaconine.—Tetra-acetylpseudaconine (2 g.) was heated in a sealed tube at 130° for 5 hours with methyl alcohol (25 c.c.). The product, which crystallised on cooling, separated from alcohol in colourless needles, m. p. 280—282°. The melting point varies with the rate of heating. Yield, 1·65 g., $[\alpha]_D$ − 18·5° (c = 0·766 in alcohol) (Found : C, 61·7; H, 7·9; OMe, 24·8; NMe, 3·7. $C_{32}H_{49}O_{11}N$ requires C, 61·6; H, 7·9; 5OMe, 24·9; NMe, 4·7%). Crystalline salts could not be obtained.

Triacetylethylpseudaconine.—In the first preparation of tetra-acetylpseudaconine (this vol., p. 1112) the compound was crystallised from ethyl alcohol and during the crystallisation to constant melting point and rotation small crops with a higher melting point and higher rotation were obtained. After a long and tedious fractionation involving more than 40 fractional crystallisations, a quantity of material was obtained whose melting point (171°) and rotation ($[\alpha]_D$ − 25·17° in alcohol, c = 1·023) were unaltered on subsequent recrystallisations; this on analysis proved to be *triacetylethylpseudaconine*. An attempt was made to prepare this compound in a simpler manner by heating tetra-acetylpseudaconine (2 g.) in a sealed tube at 120° for 47 hours with 25 c.c. of absolute alcohol. The product crystallised on cooling. After recrystallising twice from ethyl alcohol, 0·5 g. of colourless needles, m. p. 171°, $[\alpha]_D$ − 26° in alcohol (c = 0·98), were obtained, identical with the compound obtained in the fractional crystallisation of tetra-acetylpseudaconine. Subsequent crops of crystals consisted of mixtures of the two compounds (Found : C, 62·1; H, 8·2; N, 2·2; OMe, 24·0; NMe, 3·1. $C_{33}H_{51}O_{11}N$ requires C, 62·1; H, 8·1; N, 2·2; 4OMe + OEt calc. as 5OMe, 24·3; NMe, 4·55%). Crystalline salts could not be obtained.

Hydrolysis. Triacetylethylpseudaconine (3·0640 g.) was dissolved

in 400 c.c. of alcohol, 50% aqueous potassium hydroxide (3 c.c.) added, and after 40 hours the acetic acid was determined in the usual manner (p. 3098). The steam distillate required 28·5 c.c. of 0·5218*N*-sodium hydroxide: acetic acid, 29·1%. $C_{33}H_{51}O_{11}N$ requires for 3 mols. acetic acid, 28·3%. The residue from the steam distillation was made alkaline with sodium hydroxide and extracted with ether, which removed the *ethylpseudaconine*, obtained on evaporation of the solvent as a viscous syrup which did not crystallise. It is very soluble in water to an alkaline solution and in most organic solvents. Its salts are very soluble in water and were not obtained crystalline. An aqueous solution of a salt gives a white precipitate with Mayer's reagent, but no precipitate with picric acid, sodium perchlorate, sodium thiosulphate, or with mercuric, platinic, or auric chloride.

Action of Heat on Veratroylmethylpseudaconine.—Veratroylmethylpseudaconine was dried at 150° in a vacuum and then heated at 220—230° in the manner described for the preparation of pyropseudaconitine. The substance lost 1·3% in weight, darkened considerably, and was dissolved in 1% hydrochloric acid and fractionally precipitated by ammonia. The first precipitate carried with it all the colour. The subsequent fractions were colourless and on crystallisation from 50% alcohol were identified as unchanged veratroylmethylpseudaconine. The first fraction after purification as hydrobromide was also recognised as the same substance.

On heating the hydrochloride in a similar fashion at 260° for 10 minutes and passing the vapours through Volhard traps containing in the first water and in the second standard acid, the following results were obtained: (*a*) A very small amount of sublimate on the cooler part of the reaction tube. This was soluble in water to an acid solution, which gave with ferric chloride a green colour changing to red on the addition of sodium bicarbonate solution. It is probably a pyrocatechol derivative formed from the veratroyl group. (*b*) The water wash-tubes contained hydrochloric acid and methyl alcohol; the latter was identified in the usual manner by conversion into formaldehyde with hot copper and colour reactions with resorcinol and with gallic acid. (*c*) The standard acid was unchanged. The reaction tube had a strong, fishy smell, but no base could be isolated; the residue was dark brown, insoluble in water and sodium hydroxide, and partly soluble in dilute hydrochloric acid. Only tarry products were obtained from it.

Benzoylation of Pseudaconitine.—Pseudaconitine (1·0 g.) was heated on a water-bath for an hour with benzoyl chloride (2 c.c.). The product was shaken for some time with ether and water, the aqueous layer run off, and the ether extracted once with 1%

chloric acid and once with water. These two extracts were added to the first aqueous layer and the whole was extracted with ether. This extract was added to the main ethereal extract; on evaporation a mixture of benzoic acid and benzoyl chloride was obtained. The aqueous extract was warmed and agitated to remove dissolved ether, cooled, and treated with excess of sodium perchlorate solution. The precipitated perchlorate was washed well with water, dried in a desiccator, and crystallised from absolute alcohol. It formed confused colourless prisms, m. p. 236° (efferv.). Yield, 0·75 g. There remained an uncrystallisable residue (Found: OMe, 21·1, 21·0; NMe, 2·05, 1·8. $C_{43}H_{55}O_{13}N,HClO_4$ requires 6OMe, 20·8; NMe, 3·25%). The acetyl and benzoyl groups were estimated together by cold hydrolysis with alcoholic potassium hydroxide, followed by steam distillation and titration of the volatile acids [0·7434 g. of substance yielded volatile acid equivalent to 3·1 c.c. of 0·5218*N*-sodium hydroxide: volatile acid, 13·05 (calc. as acetic). $C_{43}H_{55}O_{13}N,HClO_4$ requires volatile acid (1 acetic + 1 benzoic acid calc. as acetic), 13·4%]. The acids were separated and identified by evaporation of the neutralised steam distillate to a small volume, acidification, and extraction with much light petroleum (b. p. 90—120°), which removed the benzoic acid and left the acetic acid in solution. The petroleum extract was shaken with sodium hydroxide solution, and the alkaline liquid acidified and extracted with ether, which furnished 0·1 g. of benzoic acid on evaporation, identified by its melting point (after sublimation), 121—122°, its smell, and the smell of ethyl benzoate obtained on warming it with alcohol and sulphuric acid. The acid mother-liquor from the petroleum extract was neutralised with sodium hydroxide, evaporated to dryness, and extracted with alcohol to dissolve the sodium acetate. The alcohol was evaporated, the sodium salt dissolved in water, and the silver salt precipitated by silver nitrate (Found: Ag, 63·3. Calc. for $CH_3{\cdot}CO_2Ag$: Ag, 64·7%). The residue from the steam distillate was extracted with ether (which gave veratric acid), made alkaline with sodium hydroxide, and extracted with chloroform. The latter, on evaporation, left a varnish, from which pseudaconine was obtained on crystallisation from acetone, m. p. 92—94°, $[\alpha]_D$ + 36·2°. The benzoylation product is therefore *monobenzoylpseudaconitine perchlorate*. The base was prepared from the purified perchlorate by treatment in alcoholic solution with an alcoholic solution of potassium acetate, but it was not obtained crystalline, nor could any other crystalline salt be obtained.

Acetylation of Pseudaconitine.—Pseudaconitine (2 g.) was boiled under reflux for an hour with 8 c.c. of acetyl chloride, the excess of the reagent distilled off, and the residue dissolved in water,

made alkaline with ammonia, and extracted with ether. The ethereal solution, without drying, deposited crystals; it was evaporated and the crystalline residue recrystallised from alcohol; the acetyl derivative was then obtained in colourless, stout needles, m. p. 229° (decomp.), $[\alpha]_D$ + 24·0° in chloroform (c = 1·00). Yield of pure substance, 1·7 g. (Found on substance dried at 120° in a vacuum: OMe, 23·6; NMe, 2·1. $C_{40}H_{55}O_{14}N$ requires 6OMe, 24·1; NMe, 3·75%). Acetic acid was determined in the usual manner (p. 3098), 50% sodium hydroxide solution, however, being used in place of potassium hydroxide and sufficient water added to dissolve the sodium hydroxide. This is preferable to using potassium hydroxide, as there is less danger of the presence of carbonate (0·7944 g. gave acetic acid equivalent to 5·95 c.c. of 0·5218*N*-sodium hydroxide: acetic acid, 23·5. $C_{40}H_{55}O_{14}N$ requires $3CH_3{\cdot}CO_2H$, 23·3%). Veratric acid and pseudaconine were recovered from the residue from the steam distillation as described under benzoylpseudaconitine. The compound is therefore *diacetylpseudaconitine* and its formation directly proves the presence of two hydroxyl groups in pseudaconitine which was previously indirectly shown by the formation of tetra-acetylpseudaconine (this vol., p. 1112). The salts of diacetylpseudaconitine were only obtained in an amorphous condition.

A *monoacetylpseudaconitine* was obtained (as perchlorate) in small yield, together with much amorphous material, by working in pyridine solution. Pseudaconitine (1 g.), dissolved in dry pyridine (5 c.c.), was well cooled with ice and salt and acetyl chloride (0·5 c.c.) was added carefully drop by drop. Pyridine hydrochloride separated. The reaction vessel was stoppered and kept over-night, the solution slowly becoming pink. The product was then poured into water (50 c.c.), and the opalescent solution distilled with steam to remove most of the pyridine. After cooling, the solution was treated with sodium perchlorate and the precipitate was washed with water, thoroughly dried, and crystallised from absolute alcohol. The salt was then obtained in small prisms which effloresced on exposure to air, m. p. 225—228° (efferv.); yield, 0·55 g. (Found on substance dried at 120° in a vacuum: acetic acid, 16·3. $C_{38}H_{53}O_{13}N,HClO_4$ requires for $2CH_3{\cdot}CO_2H$, 14·4%). Veratric acid and pseudaconine were recovered from the mother-liquor from the hydrolysis. The base is amorphous.

Reduction of Pseudaconitine.—Attempts were made to reduce pseudaconitine with hydrogen under pressure in the presence of an active palladium–barium sulphate catalyst, the sulphate being used in aqueous solution and the base in alcoholic solution. No experiment was successful, the alkaloid being recovered unchanged.

A similar result was obtained with the base in alcohol, Adams's platinum oxide catalyst and a trace of ferric chloride being used ("Organic Syntheses," vol. 8, p. 92).

The author desires to thank Dr. T. A. Henry for his kind advice and criticism, and Mr. H. C. Clarke for his assistance in the preparation and analysis of the products described.

WELLCOME CHEMICAL RESEARCH LABORATORIES,
LONDON, E.C. 1. [*Received, October 17th*, 1928.]

CCCCVI.—*The Action of Bromine on Strontium Oxide and its Hydrates.*

By HORACE BARRATT DUNNICLIFF, HARNAM DAS SURI, and KISHEN LAL MALHOTRA.

THE action of halogens on slaked lime was studied by Wilks (J., 1912, **101**, 366), and we now describe the action of bromine both as vapour and as a solution in carbon tetrachloride on strontium oxide and its hydrates.

The Action of Bromine on Anhydrous Strontium Oxide.—Merck's pure strontium oxide was used. Pure carbon tetrachloride (Kahlbaum) was distilled over calcium chloride; and bromine was purified by a modification of Brauner's method (*J. Amer. Chem. Soc.*, 1920, **42**, 921). After exposure to bromine vapour for some days, strontium oxide adsorbed about 1% of its weight of bromine, giving a pale dirty-brown product containing a few scarlet specks. The same proportion of bromine is adsorbed under identical conditions by dry, powdered silica. Strontium oxide shaken with a 2% solution of bromine in carbon tetrachloride for 48 hours took up 1·5% of its weight of bromine, as determined by loss of bromine from the solution. In both cases the solid lost the adsorbed bromine on exposure to the air, so chemical action had not taken place.

The Action of Bromine on Strontium Hydroxide Monohydrate.—Kahlbaum's strontium hydroxide octahydrate was recrystallised in a carbon dioxide-free atmosphere (Found: SrO, 39·15. Calc.: SrO, 39·06%). The powdered octahydrate was extracted with alcohol (b. p. 78·2°/742 mm.) in a Soxhlet apparatus under 150—170 mm. pressure for 10 hours: this is a new method for the preparation of strontium hydroxide monohydrate (Found: SrO, 73·87. Calc.: SrO, 74·21%). When the monohydrate is exposed to excess of bromine vapour, it yields a dark brown substance which resembles brom-bleaching powder (Wilks, *loc. cit.*), and from which carbon tetrachloride extracts some bromine. When this substance is kept

in a closed vessel, the brown colour gradually disappears, giving a pale yellow substance which yields no bromine to carbon tetrachloride. Quantitative action was not observed, but in a typical sample exposed for 12 days to the action of bromine vapour and then set aside in a large empty vessel until the colour was pale yellow 77% of the hydroxide had been attacked, giving, on solution in water, bromide (2·2 mols.) and hypobromite (1 mol.); bromate was absent. When exposed to moist air, the substance becomes pasty and finally contains bromide and bromate, but no hypobromite.

To investigate the nature of the reaction between carbon tetrachloride solutions of bromine and strontium hydroxide monohydrate, quantities of 1 g. of the hydroxide were shaken with bromine solutions in a thermostat at 20° for 24 hours. The liquid was then filtered from the solid, special precautions being taken to avoid loss of bromine, and the amount of bromine remaining in the solution was determined volumetrically. In Table I, c and $(c-x)$ show respectively the initial and final concentrations of bromine (mg. per 100 c.c. of solution), x mg. therefore reacting with 1 g. of the hydroxide.

TABLE I.

Action of Bromine in Carbon Tetrachloride Solution on $Sr(OH)_2,H_2O$.

c.	$(c-x)$.	x.	log $(c-x)$.	log x.	log $(x-450)$.	$\frac{(x-450)}{(c-x)^2}$.
450	Traces	450	—	—	—	—
473	6	467	0·778	2·669	1·230	—
574	15	559	1·176	2·747	2·037	44
695	110	585	2·041	2·767	2·303	42
951	239	712	2·378	2·853	2·415	42
1219	427	792	2·630	2·891	2·534	45
1515	716	799	2·855	2·903	2·543	39
1838	1025	812	3·011	2·910	2·559	36
2949	2137	812	3·330	2·910	2·559	—

When $(c-x)$ is plotted against x, a curve suggesting adsorption is obtained which cuts the axis at $x=450$ mg., and if log $(c-x)$ is plotted against log $(x-450)$, the points lie practically on a straight line. It therefore appears that a very rapid chemical action takes place in which 0·45 g. of bromine reacts with 1 g. of the hydrate in the molecular proportion $Br_2 : Sr(OH)_2,H_2O = 1 : 2·5$. After that, the resulting mixture adsorbs bromine until, at high concentrations, 1 mol. of the hydroxide has reacted with a maximum of 0·7 mol. of bromine: it is not possible to wash this product completely free from bromine. The substance obtained by desiccation to constant weight was analysed for bromine, bromide, hypobromite, and bromate by Dehn's method (*J. Amer. Chem.*

Soc., 1909, **31**, 525), and strontium was determined as sulphate (Found: Sr, 32·36; Br, extracted by CCl_4, traces; Br, as bromide, 36·10; as hypobromite, 4·54; as bromate, nil). The bromide and hypobromite correspond to 61·3% of the strontium present. Thus, when treated either with bromine vapour or with bromine in carbon tetrachloride, strontium hydroxide monohydrate gives appreciable amounts of hypobromite. Reference to the action of bromine on the octahydrate (below) shows that, when greater quantities of water are present, the hypobromite is decomposed almost as quickly as it is formed.

The Action of Bromine on Strontium Hydroxide Octahydrate.— When strontium hydroxide octahydrate was exposed to bromine vapour, a yellow, gelatinous mass containing droplets of water was formed. After standing in a vacuum desiccator for 48 hours, it contained 37·51% of bromine as strontium bromide and 8·89% as bromate; hypobromite was absent. These results give a calculated value for strontium as bromide and bromate of 25·40%, whereas the proportion of strontium actually found was 25·16%. Hence the reaction is quantitative.

When first exposed to a solution of bromine in carbon tetrachloride, strontium hydroxide octahydrate turns brown. In the dark or in daylight the colour gradually fades, and a flocculent mass containing droplets of water is formed. After several weeks, colourless, needle-shaped crystals are found on the sides of the vessel and extend far above the level of the solid phase. These crystals (roughly dried, m. p. 92°) are strontium bromide contaminated with a little bromate and water; their formation is accelerated by insolation.

In order to determine the time taken for the completion of the reaction, powdered strontium hydroxide octahydrate (1 g.) was shaken in a number of bottles at 20° with 100 c.c. of a solution of 1·594 g. (19·93 mg.-equivs.) of bromine in carbon tetrachloride for various intervals of time, and the loss of bromine from the liquid phase determined volumetrically. The results (Table II) show that, at first, a rapid chemical reaction with 200 mg. (2·50 mg.-equivs.) of bromine takes place. This is followed by a slower reaction, as shown by the increase in the value of x (mg.-equivs. of bromine consumed) with time (t, in hours), and if allowance be made for the 2·50 mg.-equivs. of bromine used in the primary reaction, a unimolecular velocity coefficient (k) is obtained for the first hour of the second reaction; thus, a being the original concentration of bromine (19·93 mg.-equivs. per 100 c.c.), $a_1 = a - 2{\cdot}50 = 17{\cdot}43$, and putting $x_1 = x - 2{\cdot}50$, we have $k = 1/t \,.\, \log a_1/(a_1 - x_1)$. By application of the method of calculation given by Dunnicliff and

Butler (J., 1921, **119**, 1384), the preliminary reaction is found to be equivalent to the change which would have taken place in 1 hour if the unimolecular reaction had proceeded smoothly from the start, for, by adding 1 hour to the observed time and using the actual values for bromine concentration and amount of bromine taken up, we obtain $k_1 = 1/(t+1) \cdot \log a/(a-x)$, the values of which are also shown in Table II. (This time-correction varies with the temperature of reaction and the concentration of the solution.) The final result of the reaction is a quantitative yield of strontium bromide and bromate (*vide infra*).

TABLE II.

The Action of Bromine in Carbon Tetrachloride on $Sr(OH)_2,8H_2O$.

t	0·000	0·083	0·25	0·50	0·75	1·00	2·00	5·00	24·00
x	2·50	2·71	3·16	3·73	4·29	4·75	6·00	7·20	7·48
x_1	0·00	0·21	0·66	1·23	1·79	2·25	3·50	4·70	4·98
$k \times 10^4$	—	636	632	636	628	600	487	273	—
$k_1 \times 10^4$	582	578	600	600	602	591	518	325	—

Effect of the Concentration of the Bromine Solution.—Strontium hydroxide octahydrate (1 g.) was placed in 100 c.c. of solutions of bromine in carbon tetrachloride of various strengths for 24 hours at 20°. In dilute solutions the whole of the bromine was taken up, but in concentrated solutions the solid gelatinised and droplets of water were observed on the surface of the liquid. The original and final (equilibrium) concentrations of bromine and the differences were :

Conc. of bromine, g. per 100 c.c.			Conc. of bromine, g. per 100 c.c.			
Original.	Final.	Diff.	Original.	Final.	Diff.	
0·391	0·000	0·391	0·895	0·313	0·582	Mean = 0·598
0·488	0·013	0·475	1·567	0·959	0·608	
0·527	0·020	0·507	1·771	1·199	0·572	
0·623	0·085	0·538	2·550	1·946	0·604	
0·786	0·224	0·562	2·925	2·302	0·623	

Thus, 1 g. of $Sr(OH)_2,8H_2O$ (0·390 g. of SrO) reacts with 0·598 g. of bromine, or $SrO : Br_2 = 1 : 1{\cdot}007$, the proportion required for equimolecular quantities of strontium bromide and hypobromite.

The hypobromite formed in the earlier stages of the reaction was estimated by treating the solid phase (washed free from bromine by carbon tetrachloride) with ammonia in a Lunge nitrometer, and measuring the nitrogen evolved. The relationship between the hypobromite content (in terms of nitrogen) and the time of exposure of 1 g. of the octahydrate to a 1% solution of bromine in carbon tetrachloride at 20° was :

Time, hours	0·25	0·50	1·00	2·00	4·00	6·00
Nitrogen (c.c. at N.T.P.)	7·75	8·6	9·35	12·1	8·25	3·75

From this it is concluded that the hypobromite is formed and decomposed almost immediately, but that, up to 2 hours, the rate of formation exceeds the rate of decomposition. At the end of the reaction, hypobromite is negligible or absent.

* From columns 2 and 3.

The gelatinous residue from each of several experiments was left in a desiccator until its weight was constant and then analysed. The vapour pressures of the crystalline bromide and bromate are low, and the water content of the final product, as found by heating with lead chromate in a current of dry air, is within reasonable agreement with the value (Table III, col. 5) found by calculation from the water of crystallisation of the salts (Table III, cols. 2 and 3). If, as these results indicate, the preliminary formation of equimolecular quantities of hypobromite and bromide is followed by the rapid decomposition of the hypobromite into bromide and bromate, one would expect the final proportion of bromide to bromate to be 5 : 1. Our ratio is uniformly lower and suggests that, in the presence of sufficient water, the excess of bromine oxidises some of the hypobromite to bromate direct (compare Dietzel and Schlemmer, *Z. anorg. Chem.*, 1925, **145**, 381). The following results, obtained by treating equal quantities of strontium hydroxide octahydrate with a 3% solution of bromine in the dark and in sunlight for 8 hours, show that the formation of bromate is favoured by insolation, and the values in the last two columns show that the reaction is quantitative :

The Action of Iodine on Strontium Oxide and its Hydrates.— Rama Krishna Bahl has carried out a similar series of experiments with iodine. There was no action with strontium oxide. With the monohydrated hydroxide, the interaction was small and the

results were inconclusive. The analyses by Schulek's method (*Z. anal. Chem.*, 1925, **67**, 142) of the samples obtained by exposing the octahydrate to the action of 5% iodine in carbon tetrachloride for 5 days at 20° are given in Table IV. The reaction proceeds slowly and is not quantitative. The samples marked *a* were

CCCCVII.—*Selective Solvent Action. Part VII. Solubilities in Mixed Solvents.*

By NORA GREGG-WILSON and ROBERT WRIGHT.

SEVERAL cases are known of increased solubility in mixed solvents, even when the solute is only slightly soluble in one constituent (Holleman and Antusch, *Rec. trav. chim.*, 1894, **13**, 277; Anglescu and Dumitrescu, *Z. physikal. Chem.*, 1928, **132**, 127). Solutes which show this behaviour are generally of a complex character, and this suggests a possible explanation of the phenomenon. A given solvent dissolves certain types of solute more easily than others: water dissolves hydroxylic compounds, benzene dissolves hydrocarbons, and alcohol has intermediate properties; it therefore seems probable that the solubility of a complex solute in different solvents is due to the action of different groups in the solute. Hence, when such a solute is added to a binary mixed solvent, each constituent of the solvent acts on the appropriate radical of the solute, and the two-fold effect on the solute may result in increased solubility.

The organic acids (except oxalic acid) and their salts are simple examples of solutes with two different groups, and such substances might be expected to show an increased solubility in aqueous alcohol. The values in Table I are taken from Seidell's results

(*U.S. Hyg. Labor. Bull. No.* 67) and from his tables, and the calculated values are based on the "mixture" rule. The results are in agreement with the view put forward, the double solvent attraction being that of the alcohol on the hydrocarbon radical and of water on the carboxyl group. It may also be noted that, if the solute is fairly soluble in both constituents, then abnormally high solubility occurs with all proportions of the mixed solvent, whereas if the solute is only slightly soluble in one constituent, then the maximum increase occurs with a mixture rich in the other constituent. Stearic acid shows no exaltation in solubility, but it is almost a hydrocarbon and has a very slight solubility in water, so an exaltation would only be expected in almost absolute alcohol.

In the present paper the work has mainly been confined to an examination of the solubility of acetanilide in a number of binary solvent mixtures. The results (Table II) are in accordance with the views put forward. The solubility in water is probably due to the carbonyl and imino-groups; alcohol will probably act, in addition, on the hydrocarbon portion of the molecule, resulting in an increased solubility for certain compositions of the mixed solvent. The effect should be greater with the higher alcohols, as they have greater solvent power for hydrocarbons. Thus the effect is absent with water–methyl alcohol, and is greater with propyl alcohol than with ethyl alcohol. Again, in alcohol–benzene mixtures, the benzene probably acts only on the phenyl group,

and the alcohol acts in addition on the carbonyl and imino-groups. The increased solubility is less marked in mixtures of the higher alcohols with benzene, for such alcohols are more similar to benzene in their solvent properties and hence the two constituents of the solvent do not have different effects. When the constituents of the mixed solvent resemble one another very closely, the solubility almost follows the mixture rule. Methyl–ethyl alcohol and ethyl–propyl alcohol mixtures behave in this manner.

The above view is, however, incomplete, since it neglects the action of the solvent constituents on one another. Solvate formation, since it decreases the latent valencies, should diminish solvent power; and dissociation, of one or both constituents due to the presence of the other, should increase it. Again, since hydrocarbons possess only one type of radical, they should not show abnormal solubility in mixed solvents. Few measurements have been made with these substances, but Tyrer (private communication to Seidell) has shown that anthracene in benzene–pentane or benzene–heptane mixtures always shows a sub-normal solubility. The results found by the authors for phenanthrene in mixtures of water and the alcohols are in Table III, and, like those for anthracene, show only a decreased solubility. On the other hand, Disselkamp (*Z. physikal. Chem.*, 1926, **123**, 99) has found an increased solubility for anthracene in several liquid mixtures, and attributes the result to interaction between the solvent constituents. He further draws a parallelism between the solvent power and the vapour pressure of a mixed solvent; but such a view must also be incomplete, since it would necessitate a constant form of solubility curve, independent of the solute, for any given binary solvent.

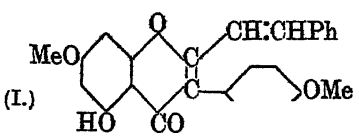
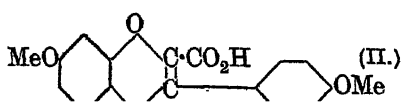
Experimental.—The methyl alcohol, ethyl alcohol, and benzene were the purest obtainable from the British Drug Houses, and boiled over a range of less than 0·1°. The propyl alcohol was prepared from the commercial product, and its b. p. varied over 1°. The determinations were carried out by shaking solvent and solute in a thermostat in a small stoppered tube, withdrawing a sample by means of a pipette, and evaporating it to dryness at 40° under diminished pressure. Preliminary tests showed that the solutes were not volatile under such treatment.

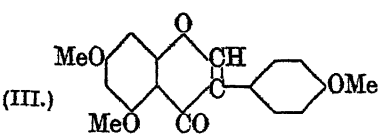
In conclusion, we desire to thank Mr. J. C. MacMaster for carrying out some of the preliminary measurements.



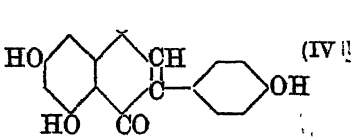
GLASGOW UNIVERSITY. [*Received, July 27th*, 1928.]



CCCCVIII.—*Synthetical Experiments in the* iso*Flavone Group. Part III. A Synthesis of Genistein.*



By WILSON BAKER and ROBERT ROBINSON.



THE synthesis of methylgenistein dimethyl ether described in Part II of this investigation (J., 1926, 2713) sufficed to determine the constitution of genistein (prunetol), and we are now able to report the synthesis of the colouring matter itself by an extension of the methods previously employed.

When 5 : 7-dihydroxy-4′-methoxy-2-styryl*iso*flavone (Baker and Robinson, *loc. cit.*) was methylated by means of methyl sulphate and methyl-alcoholic aqueous potassium hydroxide, nuclear alkylation was avoided and the product was *5-hydroxy-7 : 4′-dimethoxy-2-styryl*iso*flavone* (I), which was quite insoluble in boiling aqueous potassium hydroxide and could not be further methylated by means of methyl sulphate and potassium hydroxide in boiling methyl-alcoholic solution.

(I.) 

(III.) 

In the presence of acetone, however, the action of methyl sulphate and sodium hydroxide on the phenol led to the formation of

5 : 7 : 4′-trimethoxy-2-styrylisoflavone. We wish to direct particular attention to this modification of the usual procedure, since we have found in other cases that it is remarkably effective.

Several attempts to prepare derivatives of genisteincarboxylic acid by oxidation of the acetyl derivative of (I) were unsuccessful, but the methyl ether could be oxidised by means of potassium permanganate in aqueous pyridine solution with formation of benzoic acid and *5 : 7 : 4′-trimethoxyisoflavone-2-carboxylic acid* (II). This acid decomposes smoothly, when heated above its melting point, yielding *5 : 7 : 4′-trimethoxyisoflavone* (III) or genistein trimethyl ether. The latter has not yet been obtained from genistein, but on demethylation it furnished 5 : 7 : 4′-trihydroxy*iso*flavone (IV), identical in all respects with genistein from *Genista tinctoria*, Linn. (Perkin and Newbury, J., 1899, **75**, 830), a specimen of which was very kindly sent to us by Professor A. G. Perkin.

EXPERIMENTAL.

5-Hydroxy-7 : 4′-dimethoxy-2-styrylisoflavone (I).—Methyl sulphate and aqueous potassium hydroxide (40%) were added in small portions alternately and with shaking to a solution of 5 : 7-dihydroxy-4′-methoxy-2-styryl*iso*flavone (Part II, *loc. cit.*) (7·5 g.) in methyl alcohol (100 c.c. of 50%) and potassium hydroxide (10 g.). The deep orange-yellow colour of the solution faded. The precipitated methylated product, after being washed successively with dilute aqueous potassium hydroxide, water, and alcohol, crystallised from much alcohol in tiny, bright yellow needles, m. p. 245—246° (Found: C, 74·8; H, 5·2. $C_{25}H_{20}O_5$ requires C, 75·0; H, 5·0%). The phenolic function is feebly exercised, since, although the alcoholic solution becomes greenish-brown on the addition of ferric chloride, the substance is insoluble in dilute caustic alkali solution. The solution in sulphuric acid is intensely yellow and exhibits a weak green fluorescence.

The *acetyl* derivative was prepared in the usual manner by means of acetic anhydride. It crystallised from alcohol in thin, yellow prisms, m. p. 203—204° (Found: C, 73·1; H, 5·2. $C_{27}H_{22}O_6$ requires C, 73·3; H, 5·0%). Hydrolysis regenerated 5-hydroxy-7 : 4′-dimethoxy-2-styryl*iso*flavone, m. p. 245—246°. Attempts to oxidise this derivative to *O*-dimethylgenisteincarboxylic acid by means of potassium permanganate in acetone at − 10° to − 15° and in pyridine were fruitless.

5 : 7 : 4′-Trimethoxy-2-styrylisoflavone (Methyl ether of I).—Methyl sulphate (100 c.c.) and aqueous sodium hydroxide (100 c.c. of 20%) were added to a solution of 5-hydroxy-7 : 4′-dimethoxy-2-styryl*iso*flavone (10 g.) in acetone (400 c.c.). The mixture was

not cooled and the acetone layer, at first orange, became lemon-yellow; thereupon aqueous sodium hydroxide (50 c.c. of 20%) and methyl sulphate (50 c.c.) were added. Subsequently the liquid was kept strongly alkaline by the further gradual addition of 20% sodium hydroxide (100 c.c.). The product, obtained in theoretical yield, was precipitated by water (500 c.c.) and collected. It gave no coloration with ferric chloride in alcoholic solution and crystallised from alcohol in pale yellow, iridescent needles, m. p. 193° (Found: C, 75·3; H, 5·3. $C_{26}H_{22}O_5$ requires C, 75·4; H, 5·3%). The crystals are plank-shaped with obliquely cut ends and give an intensely yellow solution in sulphuric acid.

5 : 7 : 4′-*Trimethoxy*-2-*styryl*-6(?)-*methyl*iso*flavone*, prepared in a like manner from 5-hydroxy-7 : 4′-dimethoxy-2-styrylmethyl*iso*flavone (Part II, *loc. cit.*), crystallised from alcohol in pale yellow needles, m. p. 211° with some previous shrinking (Found: C, 75·9; H, 5·7. $C_{27}H_{24}O_5$ requires C, 75·7; H, 5·6%). A mixture of this nuclear methylated compound with its lower homologue (m. p. 193°) melted at 175—180°.

5 : 7 : 4′-*Trimethoxy*iso*flavone*-2-*carboxylic Acid* (II).—A solution of potassium permanganate (15 g.) in water (500 c.c.) at about 30° was rather quickly added to one of 5 : 7 : 4′-trimethoxy-2-styryl*iso*flavone (9 g.) in pure pyridine (500 c.c.) at about 35°. The oxidation was accompanied by a considerable rise of temperature. When the permanganate was reduced, the solution was filtered and distilled under about 100 mm. pressure until the liquid clouded and frothed excessively. The mixture was at once rendered strongly acid and while still warm the precipitated sticky orange mass was taken up in ethyl acetate. The extract was washed with water and then with aqueous sodium carbonate; the latter washings gave an ochreous precipitate on acidification. This was collected and heated with a little acetic acid in order to dissolve the impurities; the colourless, sandy residue (0·78 g.) was practically pure *trimethoxy*iso*flavone-carboxylic acid*. This derivative crystallises from acetic acid, in which it is very sparingly soluble, in satiny, microscopic, well-formed prisms, m. p. 237° (sharp but with immediate rapid decomposition) (Found: C, 63·8; H, 4·7. $C_{19}H_{16}O_7$ requires C, 64·0; H, 4·5%).

5 : 7 : 4′-*Trimethoxy*iso*flavone* (III).—The foregoing carboxylic acid was carefully heated above its melting point; the product crystallised several times from methyl alcohol in colourless, glistening, prismatic needles, m. p. 162—163° (Found: C, 69·1; H, 5·4. $C_{18}H_{16}O_5$ requires C, 69·2; H, 5·2%). It also separated under some undetermined conditions in rhombic plates, m. p. 162—163°.

5 : 7 : 4′-*Trihydroxy*iso*flavone* (Genistein, Prunetol, IV).—For the demethylation, the trimethyl ether was recovered from the methyl-

alcoholic mother-liquor, 0·52 g., m. p. 159—161°, being obtained. This was dissolved in a boiling mixture of acetic acid (10 c.c.) and acetic anhydride (5 c.c.), and colourless hydriodic acid (25 c.c., *d* 1·7) gradually introduced. After 20 minutes' boiling, two-thirds of the liquid was removed by distillation and water and sulphurous acid were added. The product was collected and acetylated by boiling for 30 minutes with acetic anhydride and a drop of pyridine. The acetyl derivative was isolated, crystallised once (m. p. 195—198°) from methyl alcohol, and then hydrolysed by boiling dilute aqueous sodium hydroxide and a few drops of alcohol. The recovered phenol crystallised from aqueous alcohol in long, colourless needles, m. p. 290—291° after softening and reddening at about 284°. A mixture with natural genistein and the latter alone exhibited an identical behaviour.

The synthetical specimen showed all the reactions of genistein as described in Part II (*loc. cit.*), and finally the characteristic dimethyl ether, m. p. 140—142°, was prepared and directly compared (mixed m. p.) with a specimen of natural origin (actually from prunetin), but no divergences of properties were noticed.

CCCCIX.—*The Oxidation of Dipinene.*

By LINDSAY HEATHCOTE BRIGGS and WALLACE FRANK SHORT.

THE methods which have been employed for the conversion of mono- and di-cyclic terpenes and their derivatives into diterpenes have been reviewed by Kondakov and Saprikin (*Bull. Soc. chim.*, 1925, **37**, 918, 1045. See also Carter, Read, and Smith, *J. Soc. Chem. Ind.*, 1925, **44**, 543T). No definite crystalline addition compounds have been obtained from these synthetic diterpenes, and it is suggested in the communications mentioned above that this is due to the presence of various isomeric diterpenes.

Kondakov and Saprikin suggested that the diterpenes obtained from pinene by the action of various polymerising agents (sulphuric acid, ferric chloride, fuller's earth, etc.) contain two six-membered rings united through a *gem*-dimethyl group, and that *cyclo*propane and *cyclo*butane rings are probably also present. Carter, Read, and Smith, on the other hand, suggested that the diterpenes which they obtained by the action of phosphoric acid on pinene, limonene, and cineole were possibly formed owing to the production and subsequent condensation of terpinene and terpineol. The terpineol

residue might become attached to position 5, 6, 7, or 8 in the terpinene molecule:

No well-characterised oxidation products have hitherto been obtained from any of the diterpenes produced by the polymerisation of mono- and di-cyclic terpenes. By applying the method of "dehydrogenating disruption" with manganese dioxide and sulphuric acid, developed by Ruzicka, to a dipinene produced by the action of hydrogen chloride and ferric chloride upon pinene, we have obtained an oxidation product from which trimellitic, terephthalic, and benzoic acids were isolated. This result supports the suggestion that diterpenes of this type contain two hexagonal nuclei united through a chain of one or two carbon atoms. Further deductions would, however, be unwarranted, because it is now well known (Carius, *Annalen*, 1868, **148**, 50; Ruzicka and Rudolph, *Helv. Chim. Acta*, 1927, **10**, 917) that some of the benzenecarboxylic acids obtained by oxidation with manganese dioxide and sulphuric acid are not produced normally from the carbon framework of the oxidised substance, but contain adventitious carboxyl groups.

Experimental.

Preparation of Dipinene.—Moist hydrogen chloride was passed into a mixture of 300 g. of pinene (b. p. 155—160°; $[\alpha]_{5770}^{16°}$ − 24·4°) with light petroleum (250 c.c.) until 87 g. had been absorbed. After another 300 g. of pinene had been added, anhydrous ferric chloride (30 g.) was introduced in small portions with stirring. This caused the solution to boil, and, after it had cooled, it was washed with sodium hydroxide and water and dried over sodium sulphate. The solvent was then removed and the residue distilled in a vacuum. The diterpene fraction was repeatedly distilled, finally over sodium, through a 10 cm. Vigreux column and 77 g. of a colourless oil were ultimately obtained, b. p. 183—184°/15 mm., $d_4^{20°}$ 0·9260, $n_D^{20°}$ 1·5174, $[R_L]_D$ 88·92 (calc. for a dicyclic diterpene, 88·76).

Oxidation of Dipinene.—A preliminary experiment showed that the physical constants were only very slightly changed when dipinene was boiled with 57% sulphuric acid for 36 hours.

Powdered manganese dioxide (370 g. of 82%) was added in small portions during ½ hour to a mixture of dipinene (22 g.), concentrated sulphuric acid (500 c.c.), and water (600 c.c.). After the mixture

had been refluxed for 2½ days, manganese dioxide (100 g.) and concentrated sulphuric acid (175 c.c.) were added and the boiling was continued until solution of the oil was complete (1 day). The product was diluted with an equal volume of water and filtered while still warm. The residual manganese dioxide was digested at 100° with dilute sodium hydroxide solution, the filtered alkaline liquid added to the acid filtrate, and the whole exhaustively extracted with alcohol-free ether. The dark brown product (approx. 6 g.) obtained was dissolved in dilute ammonia, filtered from a small quantity of gelatinous material, neutralised, and precipitated with silver nitrate. The silver salts, after being dried at 60° in a vacuum for 24 hours, were mixed with dry methyl iodide (7 g.) and absolute ether (10 c.c.), and the mixture, which became warm, was finally heated under reflux (3 hours) to complete the reaction. The product was diluted with ether, filtered, extracted with dilute sodium hydroxide solution, washed with water, and dried. (The alkaline layer contained an insignificant amount of organic material.) The residue obtained by removal of the ether was distilled in a vacuum and the following fractions were collected: (1) b. p. 50—60°/5 mm. (1·1 g.), (2) 70—80°/0·2 mm. (1·1 g.), (3) 80—140°/0·2 mm. (0·6 g.), (4) 140—150°/0·2 mm. (2·4 g.).

Fraction (1) was hydrolysed by alcoholic potassium hydroxide and yielded benzoic acid, m. p. 119—121° (Found for the silver salt: Ag, 47·3. Calc.: Ag, 47·1%) (*p*-nitrobenzyl ester, m. p. 88—89°).

Fraction (2) was recrystallised three times from hot methyl alcohol and then melted at 137—138° (methyl terephthalate melts at 140°). The acid obtained by hydrolysis sublimed without melting and was identified with terephthalic acid by analysis of the silver salt (Found: Ag, 56·5. Calc.: Ag, 56·8%) and by conversion into the *p*-nitrobenzyl ester, m. p. 263·5°.

Fraction (3) was recrystallised from methyl alcohol, but no homogeneous substance could be isolated.

Fraction (4) was only partly saponified by alcoholic potassium hydroxide and was therefore hydrolysed by heating at 150° for 8 hours with concentrated hydrochloric acid (4 parts) (compare Ruzicka, Schinz, and Meyer, *Helv. Chim. Acta*, 1923, **6**, 1091). The resulting acid was repeatedly crystallised from acetone–benzene and melted at 224°. Analysis of the silver salt (Found: Ag, 61·3. Calc. for $C_9H_3O_6Ag_3$: Ag, 61·0%) indicated that the acid was one of the benzenetricarboxylic acids. Of these, hemimellitic acid is eliminated by its melting point (190°), and trimesic acid (m. p. 380°) by the fact that the acid obtained from dipinene gave a fluorescent product on condensation with resorcinol. Somewhat discordant values, ranging from 216—218° (Schultz, *Annalen*, 1908, **359**, 129;

Aschan and Virtanen, *ibid.*, 1921, **424**, 213) to 230° (von Braun, Kirschbaum, and Schuhmann, *Ber.*, 1920, **53**, 1164), have been given as the melting point of trimellitic acid.

The authors are indebted to the Chemical Society for the loan of a vacuum pump.

CCCCX.—*The Reduction of Nitro-compounds by Aromatic Ketols. Part II. Some* o-, m-, *and* p-*Azoxy-compounds.*

By HUGH BRYAN NISBET.

IN extending the work already done (Part I, J., 1927, 2081), it has been proved that benzoin and its homologues in hot alcoholic solution under the influence of a trace of sodium ethoxide reduce nitro-groups to azoxy-groups no matter what position these occupy in the benzene ring. Whilst the reaction, as a method of preparing azoxy-compounds, still continues to be particularly successful in the case of para-compounds and more particularly in the case of para-compounds containing a carbon-to-carbon or a carbon-to-nitrogen double bond, yields of the order 50—87% being obtained, it is not so successful in the case of *o*- and *m*-compounds, the yields dropping to the order of 6—50%.

The isolation of the azoxy-compound from the accompanying diketone is the main difficulty, for only methods of fractional crystallisation can be resorted to because azoxy-compounds readily decompose when distilled, even in a vacuum, especially when in admixture with other compounds. *p*-Azoxy-compounds are usually much less soluble in common solvents than benzil and can, in general, be easily separated even in alcoholic solution. *o*- and *m*-Azoxy-compounds, however, are as soluble as or more soluble than the diketone, which is often the first product of the reaction, whilst the azoxy-compound must be isolated from the mother-liquors. In many cases it has been found impossible to isolate the azoxy-compound; but in every case examined it has been possible to separate the diketone and thus prove that the nitro-group has oxidised the ketol and has at the same time suffered reduction. This reaction is utilised in a new preparation of anisil and furil by oxidation of the corresponding ketol with nitrobenzene.

o-, *m*-, and *p*-Azoxy-compounds have been prepared from *o*-, *m*-,

and *p*-nitrobenzylideneacetophenone, 2-*o*-, 2-*m*-, and 2-*p*-nitrostyryl-3-methylchromone, and *o*-, *m*-, and *p*-nitrobenzylidene-*p*-bromoaniline. *p*-Azoxybenzylidene-*p*-toluidine has already been described (J., 1927, 2084); the m-*azoxy*-compound has now been prepared, but the *o*-azoxy-compound could not be isolated. Ethyl *p*-nitrobenzoate is reduced to ethyl *p*-azoxybenzoate, but the isolation of the esters of *m*-and *o*-azoxybenzoic acids could not be accomplished. The preparation of *o*- and *m*-azoxybenzonitrile, of azoxybenzene, and of α-azoxynaphthalene (compare Cumming and Steele, J., 1923, **123**, 2466) failed. In each case, however, benzil was separated.

EXPERIMENTAL.

Preparation of 2-Nitrostyryl-3-methylchromones.—2 : 3-Dimethylchromone was condensed with the corresponding nitrobenzaldehyde by Heilbron, Barnes, and Morton's method (J., 1923, **123**, 2565).

2-o-*Nitrostyryl*-3-*methylchromone*, $C_6H_4<\begin{matrix}CO\cdot CMe\\ \|\\ O—C\cdot CH:CH\cdot C_6H_4\cdot NO_2\end{matrix}$.

2 : 3-Dimethylchromone (2·8 g.) and *o*-nitrobenzaldehyde (2·2 g.) gave 1·6 g. of a solid which recrystallised from glacial acetic acid in yellow needles, m. p. 161° (Found: N, 4·5. $C_{18}H_{13}O_4N$ requires N, 4·55%).

2-m-*Nitrostyryl*-3-*methylchromone*. The chromone (3·4 g.) and *m*-nitrobenzaldehyde (3 g.) gave a solid which recrystallised from acetone in greenish-yellow needles (3 g.), m. p. 212° (Found: N, 4·55%).

2-p-*Nitrostyryl*-3-*methylchromone*, similarly prepared from *p*-nitrobenzaldehyde (3 g.), crystallised from glacial acetic acid in orange-yellow needles (2·8 g.), m. p. 238° (Found: N, 4·5%).

Preparation of Azoxy-compounds. General Method and Remarks.—The general method described in Part I (*loc. cit.*) was again employed. In those cases in which the azoxy-compound did not separate immediately or on standing for some time, some of the alcohol was distilled off and the reaction mixture was again kept until needles of benzil crystallised. These were filtered off and the mother-liquor was poured into water. The solid which separated (a mixture of benzil and azoxy-compound) was then dried and dissolved in the minimum quantity of benzene or xylene, and the azoxy-compound precipitated by addition of light petroleum.

A modification of the process, with benzene as a solvent and piperidine as an activator, was used in the preparation of 2-nitro-4-azoxytoluene.

p-*Azoxybenzylideneacetophenone*, $(C_6H_5\cdot CO\cdot CH:CH\cdot C_6H_4)_2N_2O$. *p*-Nitrobenzylideneacetophenone (4·2 g.) and benzoin (5·4 g.) gave 3·5 g. (87% of the theoretical yield) of the *p*-azoxy-compound,

which recrystallised from xylene in yellow flakes, m. p. 211—213° (compare Vorländer, *Ber.*, 1906, **39**, 810) (Found: N, 5·8. Calc.: N, 6·1%).

m-*Azoxybenzylideneacetophenone.* *m*-Nitrobenzylideneacetophenone (4·8 g.) and benzoin (6·5 g.) gave an oily solid which crystallised after some time. Recrystallised from dilute acetone and finally purified by dissolution in hot xylene and precipitation with light petroleum, it gave a brown, microcrystalline solid, m. p. 156—157°. Yield, 0·75 g. (6%) (Found: N, 6·1. $C_{30}H_{22}O_3N_2$ requires N, 6·1%).

o-*Azoxybenzylideneacetophenone.* *o*-Nitrobenzylideneacetophenone (4·6 g.) and benzoin (6·36 g.) gave benzil (4·5 g.) as a first product, and the mother-liquor, poured into water, gave a brown solid which crystallised from benzene and light petroleum in brown flakes, m. p. 141—142° after softening at 135°. Yield, 1·2 g. (11%) (Found: N, 6·2%).

2-p-*Azoxystyryl*-3-*methylchromone.* 2-*p*-Nitrostyryl-3-methylchromone (1·5 g.) and benzoin (1·1 g.) gave 0·6 g. (43%) of the p-*azoxy*-compound, which recrystallised from xylene in orange-yellow flakes, m. p. 289° (Found: N, 5·0. $C_{36}H_{26}O_5N_2$ requires N, 4·9%).

2-m-*Azoxystyryl*-3-*methylchromone* (0·75 g.; 62%), prepared from 2-*m*-nitrostyryl-3-methylchromone (1·3 g.) and benzoin (1·2 g.), separated from xylene as a yellowish-white, microcrystalline solid, m. p. 275·5° (Found: N, 5·0%).

2-o-*Azoxystyryl*-3-*methylchromone* (0·2 g.; 15%), obtained from 2-*o*-nitrostyryl-3-methylchromone (1·5 g.) and benzoin (1·3 g.), formed greenish-yellow needles, m. p. 202° (Found: N, 4·8%).

p-*Azoxybenzylidene*-p-*bromoaniline*, $(C_6H_4Br\cdot N{:}CH\cdot C_6H_4)_2N_2O$, (1 g.; 55%), prepared from *p*-nitrobenzylidene-*p*-bromoaniline (2 g.) and benzoin (2 g.), recrystallised from glacial acetic acid in yellowish-red plates, m. p. 218° (Found: N, 10·15. $C_{26}H_{18}ON_4Br_2$ requires N, 10·0%).

m-*Azoxybenzylidene*-p-*bromoaniline.* m-*Nitrobenzylidene*-p-*bromoaniline* was prepared by heating *m*-nitrobenzaldehyde and *p*-bromoaniline together until no more water was given off. It crystallised from alcohol in long, yellow needles, m. p. 84° (Found: N, 9·4. $C_{13}H_9O_2N_2Br$ requires N, 9·2%).

m-Nitrobenzylidene-*p*-bromoaniline (4 g.) and benzoin (4 g.) gave on standing for some time 0·7 g. (19%) of the m-*azoxy*-compound, which separated from benzene and light petroleum as a yellow microcrystalline solid, m. p. 120° (Found: N, 10·15. $C_{26}H_{18}ON_4Br_2$ requires N, 10·0%).

o-*Azoxybenzylidene*-p-*bromoaniline* (0·5 g.; 27%), obtained from

o-nitrobenzylidene-*p*-bromoaniline (2 g.) and benzoin (2 g.) after standing for 2 days, crystallised from xylene and light petroleum in yellow needles, m. p. 299° (Found: N, 10·3%).

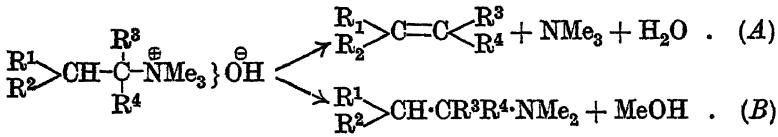
m-*Azoxybenzylidene*-p-*toluidine* (2 g.; 46%), obtained from *m*-nitrobenzylidene-*p*-toluidine (4·8 g.) and benzoin (5 g.) after standing for some time, was recrystallised, first from glacial acetic acid and then from benzene and light petroleum; it formed pale yellow needles, m. p. 150° after softening at 135° (Found: N, 13·0. $C_{28}H_{24}ON_4$ requires N, 13·0%).

Ethyl *p*-azoxybenzoate (2·75 g.; 78%), prepared from ethyl *p*-nitrobenzoate (4 g.) and benzoin (6·5 g.), crystallised from glacial acetic acid in salmon-pink needles, m. p. 117° (compare Meyer and Dahlem, *Annalen*, 1903, **326**, 334) (Found: N, 8·3. Calc.: N, 8·2%).

2-*Nitro*-3-*azoxytoluene*. A solution of 2 : 4-dinitrotoluene (5 g.) and benzoin (10 g.) in 15 c.c. of benzene containing 2 c.c. of piperidine was boiled under reflux for 6 hours. The solvent was then allowed to evaporate almost to dryness. The solid which separated, after being washed with a little cold benzene and recrystallised from glacial acetic acid and from benzene–light petroleum, formed yellowish-white needles, m. p. 164° (compare Brand and Zöller, *Ber.*, 1907, **40**, 3329). Yield, 1 g. (23%) (Found: N, 17·6. Calc.: N, 17·7%).

Preparation of Anisil and Furil.—Although azoxybenzene could not be isolated in the reduction of nitrobenzene by means of benzoin, anisoin, or furoin, by using excess of the oxidising agent it was found possible to utilise the reaction as a method of preparing anisil and furil in 80% and 90% yields, respectively. Benzil is obtained by the same reaction in yields of 30—40%.

A solution of the ketol (5 g.) and nitrobenzene (4 g.) in 50 c.c. of alcohol containing 2 c.c. of 6% alcoholic sodium ethoxide was boiled under reflux for 2—3 minutes and then allowed to cool. The diketone which separated, recrystallised from alcohol, gave 4 g. of anisil, m. p. 133°, in the case of anisoin, and 4·7 g. of furil, m. p. 162°, in the case of furoin.



The author again desires to thank Prof. A. A. Boon for his interest in the work and for providing facilities for its prosecution.

HERIOT-WATT COLLEGE, EDINBURGH. [*Received, October 8th*, 1928.]

CCCCXI.—*Influence of Poles and Polar Linkings on the Course pursued by Elimination Reactions. Part II. Mechanism of Exhaustive Methylation* (continued).

By CHRISTOPHER KELK INGOLD and CHARLES CYRIL NORREY VASS.

IN Part I,* a theory of the mechanism of the decomposition of quaternary ammonium compounds was developed and shown to be in accord with several different types of experimental data. One of the tests applied consisted in tracing the relation between the constitution of an alkyl group (Alk) and the ratio of the olefin formed to the methyl alcohol eliminated in the decomposition of the corresponding trimethylalkylammonium hydroxide (Alk·NMe_3·OH). Expanding Alk to $CHR^1R^2{\cdot}CR^3R^4{\cdot}$, and naming the simultaneous reactions referred to (*A*) and (*B*) for convenience in reference :

theory predicted that the suppression of (*A*) in favour of (*B*)

(i) should be governed by R^1 and R^2 much more than by R^3 and R^4.

(ii) should increase, tending towards constancy, with increasing R^1 and R^2.

(iii) should be greater when $R^1R^2CH{\cdot}$, or any part thereof, is branched than when the corresponding group or part is unbranched but isomeric.

In Part I, prediction (i) was established very fully, (ii) was demonstrated for groups up to and including propyl, and (iii) was confirmed for *n*- and *iso*-propyl. In the present paper, this particular test of the general theory is extended, prediction (ii) is verified up to and including hexyl, and (iii) is further established in the case of *n*- and *iso*-butyl. The results are shown in Table I.

Since the publication of Part I, the technique of these decompositions has been improved in various minor details (*e.g.*, the quantitative collection of the olefin and the more complete exclusion of carbonates and silicates from the hydroxide solution) and we have accordingly to correct the earlier values for propyl and butyl by

* The parent paper of this series (Hanhart and Ingold, J., 1927, [illegible] herein called Part I, was actually published under another (more [illegible]) title.

few units per cent.* Although it is necessary to direct attention to the results already on record (Table I), we do not propose here to discuss the cause of the large discrepancies between v. Braun's results and those obtained by us, since this point, which is of considerable interest, will be dealt with in a forthcoming paper by that author. The figures in the last column of the table we regard with confidence. In Nos. 1—7 the suppression of (*A*) with increasing R^1, and the approach to a constant value (75%) are clearly indicated (prediction ii), and the comparison of Nos. 4 and 8, in which CHR^1R^2· is *n*- and *iso*-butyl, respectively, supplies a further confirmation of (iii).

EXPERIMENTAL.

The quaternary compounds were prepared from trimethylamine and the appropriate alkyl bromide or iodide. Benz-*n*-amylamide (an intermediate in the preparation of *n*-amyl bromide from piperidine) is described by v. Braun and Sobechi as an oil (*Ber.*, 1910, **43**, 3596). Our specimens were in all cases solid and crystallised from ether–ligroin in needles, m. p. 31—32°, b. p. 205—210°/18 mm.

The method was substantially the same as in Part I, the olefins being weighed as their dibromides (Table II, column 5), and the mixed tertiary bases analysed as their methopicrates. Since the precipitation of these was never complete (Table II, column 7), the compositions deduced from their nitrogen content constitute only an approximate check (Table II, column 8). The hexene, heptene, and octene were collected in chloroform (under hydrochloric acid) and subsequently combined with bromine.

* There is theoretical reason to suspect that the proportion of olefin formed would vary *slightly* with the form of the apparatus used for distillation, so that the 3—4% difference may not all represent experimental error.

CCCCXII.—*Influence of Poles and Polar Linkings on the Course pursued by Elimination Reactions. Part III. A Decomposition of Dialkylsulphones.*

By GEOFFREY WILLIAM FENTON and CHRISTOPHER KELK INGOLD.

THE mechanism advanced in Part I (Hanhart and Ingold, J., 1927, 997) for the decomposition of quaternary ammonium hydroxides into olefins, tertiary amines, and water suggests that dialkylsulphones (Alk·SO_2·Alk′) should be capable of a similar decomposition, since the dipole in the sulphone group (Sugden, Reed, and Wilkins, J., 1925, 127, 1525; Sugden, this vol., p. 263) would be expected to induce incipient ionisation in the β-protons of each alkyl group to a sufficient degree to facilitate their union with a suitable proton-

acceptor. The products would be an olefin and an alkylsulphinic acid (*A*). Indeed the suggested analogy between

and

is complete except in two respects. The first of these is that, whereas the quaternary ammonium compound can supply its own proton-seeking anions (hydroxide), the sulphone cannot; wherefore alkali would have to be added in the latter case (*B*). The second is that the electron-affinity of $\cdot SO_2Alk$ is weaker than that of $\cdot NMe_3$ (Ingold, Ingold, and Shaw, J., 1927, 813); wherefore the effect of R→ in inhibiting the reaction (compare Parts I and II) should work more powerfully in the case of the sulphones (*C*). Otherwise we should expect most of the features which characterise the reaction of the quaternary hydroxides to apply without change to that of the sulphones, as, for instance, the rule regarding the preferential elimination of ethylene (*D*).

We have examined the action of alkali on three typical sulphones and have established the following facts:

(1) The expected decomposition of diethylsulphone occurs, the products being ethylene and ethanesulphinic acid (compare *A*). Alkali is necessary to the decomposition (compare *B*).

(2) *Ethyl*-n-*octylsulphone* similarly decomposes, giving ethylene and *n*-octanesulphinic acid, but no detectable quantity of *n*-octene or ethanesulphinic acid. This illustrates the ethylene rule (compare *D*).

(3) In contrast with the fission of trimethyl-*n*-octylammonium hydroxide, which yields some 75% of *n*-octene (compare Part II), di-*n*-octylsulphone is not decomposed at all under the conditions of reaction mentioned under (1) and (2); so that, when each β-proton is protected by the electron-source action of a *n*-hexyl group (R in the formulæ), the fission of the sulphone is inhibited completely (compare *C*).

Experimental.

Decomposition of Diethylsulphone.—Diethylsulphone (4 g., m. p. 71°, prepared from diethyl sulphide by oxidation with permanganate, and crystallised from alcohol) was mixed with ground potassium hydroxide (15 g.) and a little water, and the melt heated in a metal-bath at 200° until the vigorous evolution of gas ceased; the whole

apparatus was then swept out with a current of nitrogen. The gases were passed first through dilute hydrochloric acid (two flasks), then through liquid bromine (two flasks), and finally into an aspirator. The gas in this was proved to be free from ethane or other hydrocarbon. The hydrochloric acid solution was tested for ethyl alcohol by distilling it and treating the first portion of the distillate with *p*-nitrobenzoyl chloride and alkali; no ethyl *p*-nitrobenzoate was obtained. Thus it appears that possible hydrolysis to ethyl alcohol and ethanesulphinic acid does not correspond with the products, and that, if ethanesulphinic acid is formed in any manner, it does not break down to ethane and sulphurous acid under the conditions of the experiment. The contents of the traps containing bromine were mixed with ice, decolorised with sulphur dioxide, and made alkaline with sodium carbonate. The heavy oil was partly run off and partly extracted with ligroin, and then distilled, 3·7 g., b. p. 129—131°, being obtained. Its b. p. and analysis (Found : C, 12·4; H, 2·2. Calc. : C, 12·8; H, 2·1%) identify it as ethylene dibromide. The alkaline residue was mixed with water and dilute hydrochloric acid, during which process the odour of hydrogen sulphide was noticed, and then exactly neutralised with sodium carbonate and evaporated to dryness. The residue was extracted with alcohol, which removed sodium ethanesulphinate and traces of inorganic salts; and the latter were finally eliminated by complete evaporation of the alcohol and re-extraction of the sulphinate with the same solvent, from which it crystallised on concentration (yield, 60%). From the sodium salt (2·3 g.), barium ethanesulphinate was prepared by precipitation with barium iodide in alcoholic solution (Found : Ba, 42·4; C, 14·7; H, 3·1. Calc. : Ba, 42·5; C, 14·8; H, 3·1%).

Decomposition of Ethyl-n-octylsulphone.—Sodium (1·2 g.) was dissolved in a solution of ethyl mercaptan (3·1 g.) in ether and the ether evaporated. The residue was heated on the steam-bath for 5 hours with an alcoholic solution of *n*-octyl bromide (10 g.) and the product was poured into a large volume of water and extracted with ether. The ethyl *n*-octyl sulphide, b. p. 102—103°/11 mm., was run with rapid stirring into nitric acid, and the product poured on ice; a rapidly solidifying oil was then precipitated. On crystallisation from ligroin this yielded *ethyl-n-octylsulphone* as platelets, m. p. 68°. On one occasion the product obtained by oxidation with nitric acid remained largely liquid; it was therefore treated with powdered potassium permanganate in glacial acetic acid and the same crystalline sulphone, m. p. 68°, was obtained (Found : C, 58·4; H, 10·[illegible]. $C_{10}H_{22}O_2S$ requires C, 58·3; H, 10·7%).

The method of decomposition was that already descri[illegible] diethylsulphone and the reaction again took place smoothly [illegible];

the bath, however, was raised to 270° at the end of the process. The absence of appreciable amounts of ethane, octane, ethyl alcohol, and octyl alcohol was demonstrated. Octene, which would have collected mainly in the hydrochloric acid traps, was also absent, and the bromine solution, on being worked up for bromohydrocarbons, yielded only ethylene dibromide (b. p. 129—131°. Found: C, 13·3; H, 2·4%). The alkaline residues on acidification had an odour of hydrogen sulphide, and, following the procedure described above, sodium *n*-octanesulphinate was isolated in 70% yield. The corresponding *ferric* salt was obtained by precipitation with ferric chloride in the presence of dilute hydrochloric acid (Found: Fe, 9·6. $C_{24}H_{51}O_6S_3Fe$ requires Fe, 9·5%).

*Stability of Di-*n*-octylsulphone.*—A portion (180 c.c.) of a solution of potassium hydroxide (17 g.) in ethyl alcohol (450 c.c.) was saturated with hydrogen sulphide and added to the remainder. *n*-Octyl bromide (20 g.) was added and the mixture was kept at the ordinary temperature for 2 days, heated for 2 hours on the steam-bath, poured into a large volume of water, and extracted with ether. The di-*n*-octyl sulphide (compare Möslinger, *Annalen*, 1877, **185**, 59), b. p. 180°/10 mm., was treated (10 g.) with nitric acid (50 c.c., *d* 1·49). The oil which was precipitated by the addition of water partly solidified on keeping, and probably consisted of a mixture of di-*n*-octyl sulphoxide and di-*n*-octylsulphone. On treatment with powdered potassium permanganate in glacial acetic acid, it yielded *di-*n*-octylsulphone*, which was isolated by adding water and passing sulphur dioxide, and was purified by crystallisation from ligroin, from which it separated in platelets, m. p. 76° (Found: C, 65·9; H, 12·0. $C_{16}H_{34}O_2S$ requires C, 66·2; H, 11·8%).

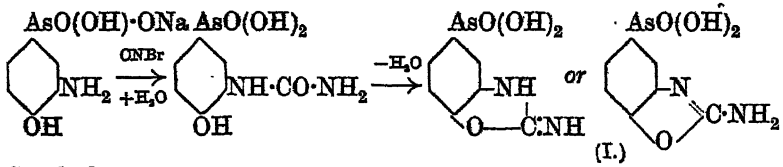
On treatment with alkali under the conditions of the previous experiments, no decomposition took place, and some unchanged sulphone collected in the first trap containing hydrochloric acid. The sulphone was therefore heated for 2 hours under reflux with 90% potassium hydroxide; again no evidence of decomposition was observed and, on cooling, the original sulphone was recovered in almost the theoretical quantity.

We wish to express our thanks to the Chemical Society for a grant in aid of this work, which is being continued.

THE UNIVERSITY, LEEDS. [*Received, October 26th*, 1928.]

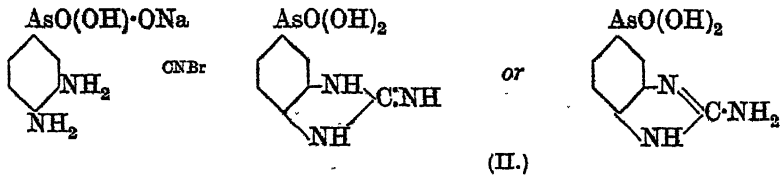
CCCCXIII.—*Heterocyclic Compounds containing Arsenic. Part IV. Carbamido-derivatives of Arylarsinic Acids.*

By RALPH WILLIAM EWART STICKINGS.



IN an attempt to prepare some guanidine derivatives of aromatic arsinic acids, the well-known reaction between a primary amine and a cyanogen halide was employed:

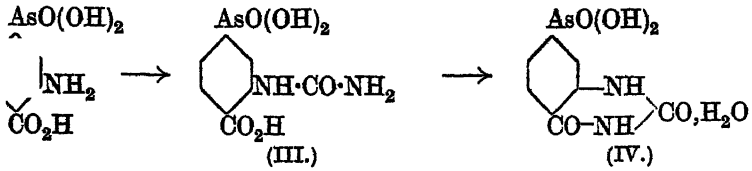
$$R{\cdot}NH_2 + CNBr \longrightarrow R{\cdot}NH{\cdot}CN + HBr.$$
$$R{\cdot}NH{\cdot}CN + R{\cdot}NH_2,HBr \longrightarrow (R{\cdot}NH)_2C{:}NH,HBr.$$



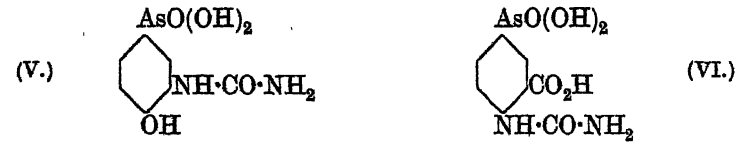
p-Arsanilic acid and cyanogen bromide, however, would not react in presence of benzene, even when boiling. Sodium *p*-arsanilate reacted rapidly with an aqueous suspension of cyanogen bromide in the cold, yielding, not a guanidine derivative, but p-*carbamidophenylarsinic acid*; of the two g.-mols. of arsanilate employed, one was recovered unchanged:

$$NH_2{\cdot}C_6H_4{\cdot}AsO(OH){\cdot}ONa + CNBr + H_2O = NH_2{\cdot}CO{\cdot}NH{\cdot}C_6H_4{\cdot}AsO(OH)_2 + NaBr.$$

No intermediate cyanamide derivative could be isolated, and it was subsequently found that this reaction was a general one with aminoarylarsinic acids. In cases where the primary amino-group is in the ortho-position to another reactive constituent group, *e.g.*, (OH) or (NH_2), the reaction proceeds further with ring formation:



Similarly



These heterocyclic compounds are soluble in mineral acids and in alkalis. They probably contain a primary amino-group, since, on diazotisation and boiling, the compound (I) yields a hydroxy-derivative. With compound (II), however, the reaction appeared to go further, the only product isolated being the original diamino-phenylarsinic acid.

If the parent arsinic acid contains a carboxyl group ortho to the amino-group, a compound is produced by the action of cyanogen bromide and water which has the properties of a diketotetrahydroquinazoline. It is insoluble in mineral acids, is not decomposed by prolonged heating with concentrated sodium hydroxide solution or 50% sulphuric acid, and on reduction with sodium hydrosulphite gives an arseno-compound insoluble in sodium hydroxide solution. On the other hand, analysis gives figures which indicate the presence of an extra molecule of water, which cannot be removed by prolonged drying in a vacuum at 110°. It appears, therefore, that this molecule of water is attached to one of the carbonyl groups in the heterocyclic nucleus and that the reaction may be represented thus :

It is inconceivable that prolonged boiling with concentrated alkali solution or acid would fail to liberate ammonia and carbon dioxide from a substituted carbamide of the type (III).

Methods (Farbwerke vorm. Meister, Lucius, & Brüning, U.S.P. 1077462, D.R.-P. 213155) for the preparation of carbamidoarylarsinic acids by the potassium cyanate method lead, according to their authors, to simple carbamide derivatives such as (V) and (VI).

This work has been confirmed in the case of (V); the compound isolated differs in properties, as would be expected, from the condensation product (I) obtained by means of cyanogen bromide.

Further work is in progress to elucidate the course of the reaction which produces these heterocyclic arsinic acids, as it has been found difficult to convert (V) into (I) by formation of the heterocyclic nucleus. An attempt is also being made to synthesise (IV) by introducing the arsinic acid group at the final stage by the Bart method.

The trypanocidal action of these compounds and of further derivatives thereof has been studied and will be reported elsewhere.

EXPERIMENTAL.

p-*Carbamidophenylarsinic Acid* (compare D.R.-P. 213155).—A solution of 108 g. of *p*-arsanilic acid in aqueous sodium hydroxide (20 g. in 500 c.c. of water) and a freshly prepared suspension of 106 g. of cyanogen bromide in 300 c.c. of water were mixed and stirred; a crystalline precipitate gradually formed and the odour of cyanogen bromide disappeared. Next day, the mixture was acidified to Congo-red with concentrated hydrochloric acid. The precipitate was collected, redissolved in aqueous sodium hydroxide, and, after the solution had been made neutral and treated with charcoal, re-precipitated with hydrochloric acid; yield, 89 g. (Found: As, 28·7; N, 10·8. $C_7H_9O_4N_2As$ requires As, 28·8; N, 10·8%). The product crystallised from hot water in glistening needles. It was sparingly soluble in cold water or organic solvents, insoluble in dilute mineral acids, and readily soluble in hot water and in caustic alkali or alkali carbonate solutions. Warming with sodium hydroxide solution liberated ammonia, and the solution on acidification with acetic acid gave carbon dioxide and *p*-arsanilic acid.

5-*Carbamido*-2-*hydroxyphenylarsinic Acid*.—5-Amino-2-hydroxyphenylarsinic acid (Fourneau, Tréfouel, and Bénoit, *Bull. Soc. chim.*, 1927, **41**, 449) (117 g.) was treated exactly as described above with 106 g. of cyanogen bromide. The product obtained on acidification was decolorised by isolation of the sodium salt and regeneration of the acid. Yield, 64 g. of white, needle-shaped crystals, soluble in hot water and in alkalis, insoluble in mineral acids (Found: As, 27·0; N, 10·3. $C_7H_9O_5N_2As$ requires As, 27·2; N, 10·1%).

1-*Aminobenzoxazole*-4-*arsinic Acid* (I).—The reaction between 3-amino-4-hydroxyphenylarsinic acid (117 g., dissolved in a solution of 20 g. of sodium hydroxide in 500 c.c. of water) and 120 g. (excess) of cyanogen bromide was complete in about 1 hour. After the addition of 10 c.c. of glacial acetic acid, the rather dark precipitate was collected and dissolved in 20% sodium hydroxide solution, which was then cooled and treated with an excess of sodium chloride. Next day, the thick mass of crystals obtained was washed with brine and decolorised in 400 c.c. of hot water with charcoal. Acidification with excess of acetic acid gave 88 g. of white prismatic needles (Found: As, 28·9; N, 10·7. $C_7H_7O_4N_2As$ requires As, 29·1; N, 10·8%).

The new *acid* is soluble in dilute mineral acids and in alkalis, and sparingly soluble in hot or cold water. It is only slowly decomposed by boiling concentrated aqueous caustic alkali.

2-*Aminobenziminazole*-5-*arsinic Acid* (II).—3 : 4-Diaminophenyl-

arsinic acid (Bertheim, *Ber.*, 1911, **44**, 3095) (116 g.) was treated exactly as described in the preceding preparation. The *product*, also purified in the same way, formed white, slender needles (55 g.), moderately easily soluble in hot water and readily soluble in dilute mineral acids or alkalis (Found: As, 29·0; N, 16·1. $C_7H_8O_3N_3As$ requires As, 29·2; N, 16·3%).

1-*Amino*-6-*acetamidobenzoxazole*-4-*arsinic Acid*.—A neutral solution of 28 g. of 3-amino-5-acetamido-4-hydroxyphenylarsinic acid (this vol., p. 2376) in dilute aqueous sodium hydroxide was diluted to 150 c.c. and added rapidly to an aqueous suspension of cyanogen bromide freshly made from 18 g. of bromine, and the whole was well stirred. After 1 hour, the product was acidified with acetic acid in excess and the brown crystals obtained were treated in alkali solution with charcoal and reprecipitated as white, prismatic needles (20 g.), readily soluble in dilute mineral acids and in alkalis (Found: As, 23·2; N, 13·2. $C_9H_{10}O_5N_3As$ requires As, 23·8; N, 13·3%).

2 : 4-*Diketo*-1 : 2 : 3 : 4-*tetrahydro*-1 : 3-*quinazoline*-7-*arsinic Acid* (IV).—3-Amino-4-carboxyphenylarsinic acid (26 g.) in neutral solution was similarly treated with cyanogen bromide (from 15 g. of bromine) and left for 1 hour in a warm place. The crystalline precipitate obtained on acidification (to Congo-red) with hydrochloric acid was recovered, after the usual purification with charcoal, in white prisms (18 g.), which were dried at 110° (Found: As, 24·4; N, 9·3. $C_8H_7O_5N_2As$ requires As, 26·2; N, 9·8%. $C_8H_7O_5N_2As,H_2O$ requires As, 24·7; N, 9·2%).

The author's thanks are due to Messrs. May & Baker Ltd., Battersea, for permission to publish this work.

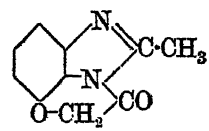
CCCCXIV.—*Heterocyclic Compounds of Arsenic. Part V. Benziminazolearsinic Acids.*



By MONTAGUE ALEXANDRA PHILLIPS.

IT has previously been shown (Phillips, this vol., pp. 172, 2393) that 2-substituted benziminazoles can readily be obtained from mono- and di-acyl-*o*-diamines by the action of boiling dilute mineral acids and from *o*-diamines by the action of organic acids in the presence of boiling dilute mineral acids. It is now shown that these reactions may be employed for the synthesis of benziminazolearsinic acids. 3 : 4-Diaminophenylarsinic acid gives with formic, acetic, propionic,

and lactic acids, respectively, benziminazole-5(6)-arsinic acid, 2-methyl-, 2-*ethyl*-, and 2-*α-hydroxyethyl-benziminazole*-5(6)-*arsinic acids*. Similarly, 2-*methyl*- and 2-*α-hydroxyethyl-benziminazole*-4(7)-*arsinic acids* and *benziminazole*-4(7)-*arsinic acid* were obtained from 2 : 3-diaminophenylarsinic acid. 3 : 4-Diacetamidophenylarsinic acid, on treatment with boiling dilute hydrochloric acid, gave 2-methylbenziminazole-5(6)-arsinic acid, which was also obtained by the application of the Bart reaction to 5-amino-2-methylbenziminazole. In no case except that of 2-α-hydroxyethylbenziminazole-5(6)-arsinic acid was the cyclic compound obtained in the absence of the catalyst.

The action of dibasic acids on the above diaminophenylarsinic acids calls for special note (compare Phillips, this vol., p. 2397). Malonic acid and 3 : 4-diaminophenylarsinic acid in the presence of boiling dilute hydrochloric acid gave an amorphous compound which appeared to be malon-*o*-phenyleneamide-4-arsinic acid, identical with the substance obtained by Lewis and Bent (*J. Amer. Chem. Soc.*, 1926, **48**, 949) from 3 : 4-diaminophenylarsinic acid and malonic ester. Oxalic acid under the same conditions gave a quantitative yield of 2 : 3-*dihydroxyquinoxaline*-6(7)-*arsinic acid* identical with the product obtained in this laboratory by the reduction of 3-nitro-4-oxalylaminophenylarsinic acid and by the action of oxalyl chloride on 3 : 4-diaminophenylarsinic acid. In all cases it was obtained as a monohydrate which did not lose water at 100°. It is possibly, therefore, a dihydroxy-derivative of formula (I).

(I.) 

(II.)

The arseno-derivative obtained by reduction of compound (I) was insoluble in alkalis and dilute mineral acids; the isomeric 2-carboxybenziminazolearsinic acid formula is therefore untenable (compare Phillips, this vol., p. 2398).

2 : 3-Diaminophenylarsinic acid condensed similarly with oxalic acid under the above conditions, giving a good yield of 2 : 3-*dihydroxyquinoxaline*-5(8)-*arsinic acid*, which was also obtained as a monohydrate stable at 100°.

The action of succinic or benzoic acid and derivatives of the latter on 3 : 4-diaminophenylarsinic acid gave no crystalline product.

Although 5-amino-3-hydroxy-1 : 4-benz*iso*oxazine and [illegible] 6-arsinic acid (Newbery and Phillips, this vol., p. 3048; Newbery, Phillips, and Stickings, *ibid.*, p. 3057) behave similarly to [illegible]-amino-

acetanilide towards nitrous acid, forming triazoles, complex benziminazoles of the type (II) could not be obtained from them by the action of acetic anhydride and boiling dilute hydrochloric acid or from their acetyl derivatives by treatment with boiling dilute mineral acids.

Attempts to nitrate 2-methylbenziminazole-5(6)-arsinic acid under a variety of conditions gave either unchanged material or mixtures from which no crystalline substance could be obtained; similar results were recorded for 3 : 4-diacetamidophenylarsinic acid.

Experimental.

3 : 4-Diacetamidophenylarsinic acid could not be obtained by acetylation of 3 : 4-diaminophenylarsinic acid (compare Baxter and Fargher, J., 1919, **115**, 1372), but was prepared in 50% yield by decomposing a diazotised solution of 4-amino-1 : 2-diacetamidobenzene (Phillips, this vol., p. 175) (8 g.; 60 c.c. of ice-water; 8 c.c. of hydrochloric acid, *d* 1·16; 2·8 g. of sodium nitrite) at 50° with a copper arsenite suspension (5 g. of arsenious oxide; 6 g. of sodium hydroxide in 50 c.c. of water; 8 c.c. of 2*N*-copper sulphate). The solution was then acidified to litmus, filtered from amorphous material, acidified to Congo-red, and concentrated to 50 c.c. The arsinic acid obtained crystallised from concentrated aqueous solution in colourless needles, m. p. 320° (decomp.), readily soluble in cold water (Found: As, 24·0; N, 9·0. Calc.: As, 23·7; N, 8·9%).

2-Methylbenziminazole-5(6)-arsinic acid, obtained by Baxter and Fargher (*loc. cit.*) by treatment of the above arsinic acid with water in a sealed tube, was best prepared (*a*) by refluxing the above acid (4 g.) with 5*N*-hydrochloric acid (20 c.c.) for 40 minutes and neutralising the filtered solution to Congo-red; yield, 2·5 g. (78%). It was also obtained (*b*) by boiling under reflux 3 : 4-diaminophenylarsinic acid (4 g.; Bertheim, *Ber.*, 1911, **44**, 3095) with 5*N*-hydrochloric acid (30 c.c.) and acetic acid or anhydride (2 c.c.) for 40 minutes and neutralising the filtered solution to Congo-red; yield, 2 g. (40%). (*c*) A diazotised solution of 5-amino-2-methylbenziminazole dihydrochloride (22 g.; water, 100 c.c.; sodium nitrite, 7 g.) was decomposed at 50° with copper arsenite (arsenious oxide, 15 g.; sodium hydroxide, 15 g.; 2*N*-copper sulphate, 6 c.c.; water, 100 c.c.); yield, 30%.

2-Methylbenziminazole-5(6)-arsinic acid (m. p. 275°, decomp., when anhydrous) was obtained in all cases as a monohydrate (Found: As, 27·3; N, 10·0. Calc.: As, 27·4; N, 10·2%), which lost half its water at 100° and the rest only slowly at 120° (Found in anhydrous substance: As, 29·4; N, 10·8. Calc.: As, 29·3; N, 10·9%). It consists of colourless prisms, sparingly soluble in

cold water, but readily soluble in mineral acids and in alkalis. The calcium and magnesium salts are amorphous. The acid contains no free amino-group as shown by the diazo-alkaline β-naphthol test. The *nitrate* (Found: As, 24·0. N, 13·45. $C_8H_9O_3N_2As,HNO_3$ requires As, 23·5; N, 13·2%) was obtained in white needles in quantitative yield by the action of boiling 10% nitric acid on the arsinic acid.

2 : 2′-*Dimethyl*-5 : 5′-*arsenobenziminazole*, obtained in 60% yield by hyposulphite reduction of the above arsinic acid, was a deep yellow, amorphous solid, insoluble in water and alkalis, soluble in dilute mineral acids. It contains no free amino-group as shown by the diazo-alkaline β-naphthol test. On desiccation in a vacuum it retained 4 molecules of water, one of which was removed with difficulty at 90° (Found: As, 32·0; N, 11·85; H_2O lost at 90°, 3·9. $C_{16}H_{14}N_4As_2,4H_2O$ requires As, 31·0; N, 11·6; $1H_2O$, 3·95%).

The following three acids were obtained by refluxing 3 : 4-diaminophenylarsinic acid with 5*N*-hydrochloric acid and formic, propionic, or *l*-lactic acid for 1 hour, treating the solution with charcoal, and neutralising it to Congo-red or litmus.

Benziminazole-5(6)-arsinic acid crystallised from water in diamond-shaped plates, identical with the material obtained by Baxter and Fargher's method (*loc. cit.*) (Found: As, 31·2; N, 11·6. Calc.: As, 31·0; N, 11·6%). On reduction with sodium hyposulphite, it gave 5 : 5′-*arsenobenziminazole* in 60% yield as a yellow amorphous solid, insoluble in water, alkalis, and organic solvents, soluble in dilute mineral acids, and containing no free amino-group (Found: As, 38·6; N, 14·4. $C_{14}H_{10}N_4As_2$ requires As, 39·0; N, 14·6%).

2-*Ethylbenziminazole*-5(6)-*arsinic acid* was purified by the method suggested by Christiansen (*J. Amer. Chem. Soc.*, 1920, **42**, 2403) for 3-amino-4-hydroxyphenylarsinic acid. It formed clusters of needles, moderately easily soluble in cold water and alcohol, readily soluble in alkalis and dilute mineral acids. The calcium salt separates from a hot aqueous solution in clusters of prisms, soluble in cold water; the magnesium salt is amorphous (Found: As, 27·5; N, 10·5. $C_9H_{11}O_3N_2As$ requires As, 27·8; N, 10·4%).

2-α-*Hydroxyethylbenziminazole*-5(6)-*arsinic acid*, purified by acidification of its alkaline solution, formed colourless needles, insoluble in cold water and sparingly soluble in boiling water. It forms an amorphous magnesium salt (Found: As, 26·4; N, 10·0. $C_9H_{11}O_4N_2As$ requires As, 26·2; N, 9·8%). The acid was also obtained (yield, 1 g. or 40%) when 3 : 4-diaminophenylarsinic acid (2 g.) was heated in a boiling water-bath for 1 hour with *l*-lactic acid (5 c.c.), and the solution then diluted with water (3[illegible]) (Found: As, 26·0%).

2 : 3-Diaminophenylarsinic acid has been obtained (D.R.-P. 256343) by reduction of 2-nitro-3-aminophenylarsinic acid. That required for this investigation was, however, prepared as follows: 2-Nitro-3-carbethoxyaminophenylarsinic acid (5 g.) (Newbery, Phillips, and Stickings, this vol., p. 3053) was dissolved without cooling in a solution of sodium hydroxide (5 g.) in water (25 c.c.), and glucose (4 g.) was added immediately. A reaction occurred during which no ammonia was liberated. When this had subsided, the liquid was boiled for 5 minutes, acidified strongly to Congo-red, treated with charcoal, and filtered. On neutralisation to Congo-red with 10*N*-sodium hydroxide and cooling, the diamino-acid separated (yield, 1·5 g. or 45%). Purified by Christiansen's method (*loc. cit.*), it consisted of colourless plates, m. p. 198° (decomp.), sparingly soluble in water. The calcium, barium, and magnesium salts are relatively soluble and the acid gives a rich red colour with acidified dichromate solution. It differs considerably from the isomeric 3 : 4-diaminophenylarsinic acid, which gives a characteristic insoluble calcium salt (plates), decomposes at 158°, and gives a purple colour with acidified dichromate solution. This acid, moreover, is considerably more basic than 2 : 3-diaminophenylarsinic acid. The orientations of the latter acid, which is undoubtedly an *o*-phenylenediamine derivative, and of 2-nitro-3-carbethoxyaminophenylarsinic acid would therefore appear to be firmly established. *Benziminazole-4(7)-arsinic acid*, obtained from 2 : 3-diaminophenylarsinic acid and formic acid as described under benziminazole-5(6)-arsinic acid, forms colourless prisms, m. p. 277° (decomp.), from boiling water, in which it is sparingly soluble (Found: As, 30·9; N, 11·5%). It is markedly amphoteric, but appears to be somewhat less basic than the 5(6)-arsinic acid. The calcium salt is amorphous, and soluble in cold but insoluble in boiling water; the magnesium salt forms clusters of colourless prisms. *4 : 4'-Arsenobenziminazole* is an amorphous yellow solid (Found in substance dried at 100°: As, 38·8; N, 14·5%), insoluble in water, alkalis and organic solvents, but soluble in dilute hydrochloric acid to give a hydrochloride, which is precipitated by excess of the mineral acid.

2-Methylbenziminazole-4(7)-arsinic acid, obtained in 50% yield from 2 : 3-diaminophenylarsinic acid and acetic anhydride in the presence of boiling 4*N*-hydrochloric acid, forms anhydrous needles, m. p. 280—282°, from boiling water (Found: As, 28·9; N, 10·7%). It is readily soluble in alkalis and dilute mineral acids. Its magnesium and calcium salts are amorphous.

2 : 2'-Dimethyl-4 : 4'-arsenobenziminazole is a yellow, amorphous solid, resembling its lower homologue in all its properties. It can

readily be dried in a vacuum, differing from 2 : 2′-dimethyl-5 : 5′-arsenobenziminazole (p. 3137) in this respect (Found: As, 36·0; N, 13·3. $C_{16}H_{14}N_4As_2$ requires As, 36·4; N, 13·6%).

2-α-*Hydroxyethylbenziminazole*-4(7)-*arsinic acid* was obtained in poor yield from 2 : 3-diaminophenylarsinic acid, *l*-lactic acid, and 4*N*-hydrochloric acid. It forms colourless needles from boiling water, is amphoteric, and gives an amorphous magnesium salt (Found: As, 26·0; N, 9·5%).

Condensation of Dibasic Acids with 2 : 3- *and* 3 : 4-*Diaminophenylarsinic Acids.*—(1) *Oxalic acid.* (a) 3 : 4-Diaminophenylarsinic acid (2 g.), 4*N*-hydrochloric acid (14 c.c.), and crystalline oxalic acid (1·2 g.) were boiled under reflux for 40 minutes. On cooling, 2 : 3-*dihydroxyquinoxaline*-6(7)-*arsinic acid* separated (yield, 1·5 g. or 60%). Crystallised many times from boiling water, in which it was very sparingly soluble, it formed colourless hexagonal plates, not molten at 300° (Found: As, 25·0; N, 9·2. $C_8H_7O_5N_2As,H_2O$ requires As, 24·8; N, 9·2%). It is insoluble in dilute mineral acids, but readily soluble in alkalis, giving with sodium hydroxide mono- and di-sodium salts. It also forms very sparingly soluble calcium, barium, and magnesium salts.

(b) 2 : 3-Diaminophenylarsinic acid, treated similarly, gave a 75% yield of 2 : 3-*dihydroxyquinoxaline*-5(8)-*arsinic acid*, which crystallised in prisms not molten at 300°. Like its isomeride, it is very sparingly soluble in boiling water and gives very sparingly soluble calcium, barium, and magnesium salts (Found: As, 24·9; N, 9·2. $C_8H_7O_5N_2As,H_2O$ requires As, 24·7; N, 9·2%). The arseno-derivative has properties identical with those of the compound derived from the isomeric 6(7)-arsinic acid.

(2) *Malonic acid.* (a) 3 : 4-Diaminophenylarsinic acid (2 g.), malonic acid (1 g.), and 4*N*-hydrochloric acid (14 c.c.), boiled under reflux for 1 hour, gave a trace only of red, amorphous material on cooling. The filtrate contained about 1 g. of unchanged diamino-acid. The red material was purified by solution in glacial acetic acid and reprecipitation by ether. It was insoluble in water, dilute mineral acids, and most organic solvents, but readily soluble in alkalis, giving neutral solutions (Found: As, 24·8%).

(b) 3 : 4-Diaminophenylarsinic acid, treated in methyl alcohol with ethyl malonate as described by Lewis and Bent (*loc. cit.*), gave the same material, which was purified similarly and dried at 90°. It appears to be malon-*o*-phenyleneamide-4-arsinic acid and, unlike the quinoxalinearsinic acids, gives soluble calcium, barium, and magnesium salts (Found: As, 24·8; N, 9·2. Calc. for $C_9H_9O_5N_2As$: As, 25·0; N, 9·3%).

(3) *Succinic acid.* 3 : 4-Diaminophenylarsinic acid (2 g., 4*N*-

hydrochloric acid (14 c.c.), and succinic acid (2 g.) gave, on refluxing for 1 hour and cooling, a 60% return of unchanged 3 : 4-diaminophenylarsinic acid. No cyclic arsinic acid could be detected.

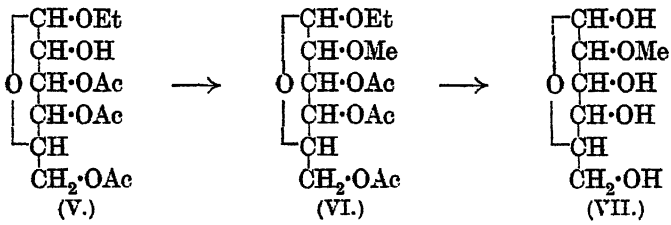
CCCCXV.—*Glucosides. Part I. The Formation of Glucosides from 3 : 4 : 6-Triacetyl Glucose 1 : 2-Anhydride.*

By WILFRED JOHN HICKINBOTTOM.

A TRIACETYL glucose anhydride has been prepared by Brigl (*Z. physiol. Chem.*, 1922, **122**, 257), who described it as a crystalline solid which reacted with methyl alcohol to yield a triacetyl β-methylglucoside. This anhydride may therefore prove to be a valuable general reagent for the preparation of glucosides, and more particularly of glucosides which are not obtained conveniently by the usual standard methods. Its reactions with a number of substances have been investigated; those with phenol and with alcohols are here recorded.

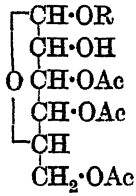


Brigl assigned to the triacetyl glucose anhydride the formula (I) on the basis of its formation from triacetyl glucosyl chloride (II), the structure of which has been determined by its conversion into a triacetyl dichloroglucose (III) and subsequent reduction to triacetyl glucal (IV).

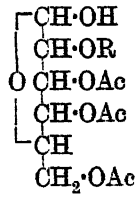
(I.) (II.) (III.) (IV.)

This formulation of the triacetyl glucose anhydride has been confirmed by an independent method. The anhydride was converted, by the interaction of ethyl alcohol and the ethylene oxide group, into 3 : 4 : 6-*triacetyl* β-*ethylglucoside* (V), which, by methylation with methyl iodide in presence of silver oxide, yielded a *triacetyl methyl* β-*ethylglucoside* (VI). Deacetylation by means of alcoholic ammonia, followed by hydrolysis, gave a monomethyl glucose. This sugar was characterised by its *phenylhydrazone*. No phenylosazone could be obtained from it. It must be therefore

2-methyl glucose (VII), as the methyl group can only replace the hydrogen of the remaining hydroxyl group in triacetyl β-ethyl-glucoside.



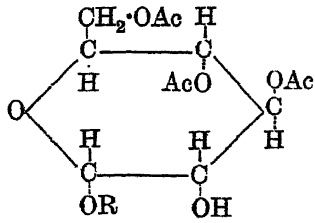
3 : 4 : 6-Triacetyl glucose anhydride reacts similarly with other primary and with secondary alcohols at room temperature to yield β-glucosides: methyl alcohol gives a product consisting principally of 3 : 4 : 6-triacetyl β-methylglucoside (compare Brigl, *loc. cit.*), *iso*propyl alcohol furnishes 3 : 4 : 6-triacetyl β-*iso*propylglucoside, and menthol gives 3 : 4 : 6-triacetyl β-menthylglucoside. The last glucoside appears to be identical with the product obtained by Fischer and Bergmann (*Ber.*, 1917, **50**, 711) from the reaction of menthol with tetra-acetyl glucosyl bromide in presence of quinoline. If it is, there must be in Fischer and Bergmann's product a free hydroxyl in position 2. This conclusion is supported by other observations which show that in the tetra-acyl glucosyl halides an acyl group is more readily removed from position 2 than from position 3, 4, or 6. For instance, in 2 : 3 : 4 : 6-tetra-acetyl glucosyl bromide the acetyl group in position 2 is eliminated on reduction to triacetyl glucal. Also 2-trichloroacetyl-3 : 4 : 6-triacetyl glucosyl chloride yields 3 : 4 : 6-triacetyl glucose by combined reduction and regulated hydrolysis (Hickinbottom, unpublished observation) and 3 : 4 : 6-triacetyl glucosyl chloride by carefully controlled deacylation (Brigl, *loc. cit.*).



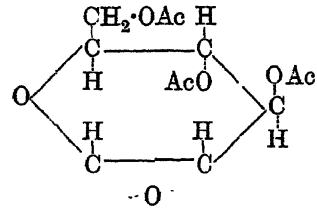
The combination of 3 : 4 : 6-triacetyl glucose anhydride with phenols proceeds less readily than with primary and secondary alcohols. The anhydride and phenol at 80—100° yield a triacetyl phenylglucoside. This was identified as an α-glucoside by conversion into α-phenylglucoside and into tetra-acetyl α-phenylglucoside and comparison of these substances with authentic specimens. This method of preparing α-phenylglucoside is more convenient than that described by Fischer and Mechel (*Ber.*, 1916, **49**, 2813), *viz.*, the condensation of phenol with tetra-acetyl glucosyl bromide in the presence of quinoline, which yields also a considerable proportion of acetyl[illegible] β-phenylglucosides.

In all the cases so far examined, the products of the con[illegible] of 3 : 4 : 6-triacetyl glucose anhydride (I) with hydroxy-com[illegible]

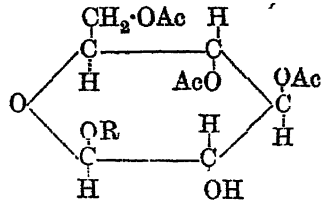
are glucosides of the type (VIII), no derivative of a 2-alkyl glucose (IX) having yet been isolated.



(VIII.)



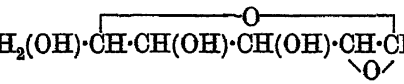
(IX.)



To show the relative dispositions of the groups in space, 3 : 4 : 6-triacetyl glucose anhydride may be formulated as in (X).

(XI.)

(X.)



(XII.)

Then (XI) will represent its α-glucosides, and (XII) the corresponding β-glucosides (compare Drew and Haworth, J., 1926, 2305). It is seen that the formation of β-glucosides by the additive union with alcohols involves the opening of the ethylene oxide ring so that the added groups occupy the *trans*-position. Kuhn and Ebel (*Ber.*, 1925, **58**, 919) also have demonstrated the *trans*-fission of the ethylene oxide ring in *cis*-oxidoethylene-αβ-dicarboxylic acid to yield *r*-tartaric acid. If it be a general behaviour of ethylene oxide rings to yield compounds having *trans*-configurations on fission, it is difficult to explain the formation of 3 : 4 : 6-triacetyl α-phenylglucoside from 3 : 4 : 6-triacetyl glucose anhydride by the action of phenol, unless the α-configuration attributed to the phenylglucoside had been wrongly assigned. The spatial distribution of the glucosidic residue with respect to the rest of the molecule may, however, be deduced from other considerations, *e.g.*, the behaviour towards enzymes, the optical rotatory power, and the formation from glucosyl halides. The evidence from these sources indicates clearly

that the configuration of α-phenylglucoside is not similar to that of β-glucosides.

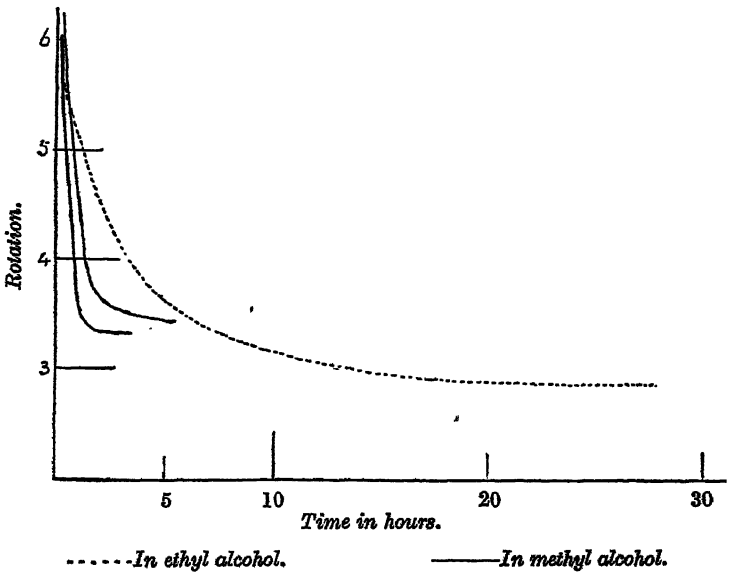
3 : 4 : 6-Triacetyl glucose anhydride, then, may yield either *cis*- or *trans*-fission products according as it reacts with phenol or alcohols. It appears, therefore, that the configuration of the product resulting from the opening of an ethylene oxide ring cannot be predicted without reference to the nature of the reactants, and probably also to the conditions during the reaction.

α-Glucosan, according to the structure assigned to it by Pictet and Castan (*Helv. Chim. Acta*, 1920, **3**, 645),

should be the parent substance of 3 : 4 : 6-triacetyl glucose anhydride. The reactions of the two substances differ so widely, however, as to shed doubt on the accuracy of the above structure.

The ethylene oxide ring in α-glucosan is surprisingly stable to reagents in comparison with that in triacetyl glucose anhydride. For instance, α-glucosan may be benzoylated or methylated by means of benzoyl chloride or methyl sulphate in presence of aqueous sodium hydroxide, and it combines additively with methyl iodide in methyl-alcoholic solution at 120° (Cramer and Cox, *Helv. Chim. Acta*, 1922, **5**, 884). Pictet and Castan isolated α-glucosan in a crystalline state by solution in cold methyl alcohol, followed by evaporation at room temperature. Under similar conditions, the ethylene oxide ring in 3 : 4 : 6-triacetyl glucose anhydride, possibly rendered more reactive by the presence of the acyl groups, is opened with the formation of 3 : 4 : 6-triacetyl β-methylglucoside.

The anhydride reacts rapidly with methyl alcohol at room temperature, the formation of the glucoside being complete in about 2 hours for a 5% solution. The rate of reaction with ethyl alcohol is slower, but is sufficiently rapid to prevent the anhydride being purified by crystallisation from this solvent. The graphs in Fig. 1 record the change of optical rotation with time for solutions of 3 : 4 : 6-triacetyl glucose anhydride in methyl and ethyl alcohols.



EXPERIMENTAL.

Preparation of 3 : 4 : 6-*Triacetyl Glucose* 1 : 2-*Anhydride* (I) (compare Brigl, *loc. cit.*).—A current of dry ammonia was slowly passed through a suspension of dry, finely powdered 3 : 4 : 6-triacetyl glucosyl chloride in 8—10 times its weight of dry benzene for 3 hours; the mixture was then kept and occasionally shaken in a sealed flask for 15 hours. The ammonium chloride having been removed, and washed with benzene, the filtrate and the washings

were freed from ammonia in a partial vacuum over concentrated sulphuric acid, and the benzene was evaporated under diminished pressure at 40°; addition of light petroleum (b. p. 40—60°) then yielded a crystalline cake of 3 : 4 : 6-triacetyl glucose 1 : 2-anhydride. It separated from a mixture of benzene and light petroleum or from the latter solvent alone in platelets, m. p. 57—58° after sintering at 56°.

The anhydride may also be obtained by shaking with silver oxide a suspension of 3 : 4 : 6-triacetyl glucosyl chloride in dry chloroform for 20 hours. The product, however, is coloured and impure.

FIG. 1.

Reaction of 3 : 4 : 6-*Triacetyl Glucose* 1 : 2-*Anhydride with Hydroxy-compounds.*

With Methyl Alcohol. Formation of 3 : 4 : 6-*Triacetyl* β-*Methyl-glucoside.*—The reaction, which took place readily in the cold, was followed polarimetrically ($l = 2$; $c = 4{\cdot}89$).

t (mins.)	7·	15	20	25	30	40	60	120	180
α_D.....	+6·11°	5·18°	4·88°	4·60°	4·37°	4·02°	3·67°	3·34°	3·32° (const.)

Similar results were obtained when methyl alcohol containing a trace of methylamine was used as solvent.

Evaporation of the solvent yielded a viscid residue, from which, by crystallisation from absolute alcohol, pure 3 : 4 : 6-triacetyl

β-methylglucoside was obtained in prisms, m. p. 95—97°, $[\alpha]_D$ + 19° (Brigl, *loc. cit.*, gives m. p. 96—98°, $[\alpha]_D$ + 9·4°).

Acetylation in pyridine yielded tetra-acetyl β-methylglucoside which, alone or mixed with a genuine specimen, melted at 101—103°.

With Ethyl Alcohol. Formation of 3 : 4 : 6-*Triacetyl* β-*Ethylglucoside* (V).—A solution of 3 : 4 : 6-triacetyl glucose anhydride in ethyl alcohol deposited on spontaneous evaporation 3 : 4 : 6-*triacetyl* β-*ethylglucoside* in prisms, m. p. 121°, $[\alpha]_D$ + 14·4° in ethyl alcohol (*c* = 2·57) (Found: C, 50·1; H, 6·7. $C_{14}H_{22}O_9$ requires C, 50·3; H, 6·6%). By slow crystallisation from ethyl alcohol, massive prisms may be obtained having bevelled ends and hexagonal cross-section.

The following rotations were observed for a solution of the anhydride in ethyl alcohol (*c* = 4·81, *l* = 2) at 22°:

t (hrs.)	0·13	0·20	0·33	0·55	0·88	1·00	1·67
α_D	+5·90°	5·87°	5·74°	5·57°	5·32°	5·23°	4·75°
t (hrs.)	3·07	3·83	4·85	22·20	26·70		
α_D	4·15°	3·82°	3·63°	2·84°	2·89° (const.)		

The end-point may be reached more rapidly by heating the solution.

The observed constant rotation gives $[\alpha]_D$ + 25·9°, calculated as for triacetyl ethylglucoside. This value is greater than the specific rotation for pure triacetyl β-ethylglucoside in ethyl alcohol. In other experiments also, both with methyl and with ethyl alcohol, the specific rotation of the final solution was greater than that of the pure β-glucoside. It is evident that a small quantity of another substance having a relatively high specific rotation is formed.

Acetylation of the triacetyl β-ethylglucoside with acetic anhydride in pyridine solution gave 2 : 3 : 4 : 6-tetra-acetyl β-ethylglucoside, m. p. 105—106°, which was identified by comparison with a genuine specimen (Found: C, 51·6; H, 6·4. Calc.: C, 51·15; H, 6·6%).

Methylation of 3 : 4 : 6-*triacetyl* β-*ethylglucoside. Formation of* 3 : 4 : 6-*triacetyl*-2-*methyl* β-*ethylglucoside.* Pure triacetyl β-ethylglucoside (0·76 g.) dissolved in an excess of methyl iodide (18 g.) was heated under reflux, with the addition of pure dry silver oxide at intervals during a period of 30 hours. A further 10 g. of methyl iodide was then added, and the heating continued for 10 hours. Dilution with ether, filtration, washing with ether, and evaporation of the filtrate and washings under diminished pressure gave a syrup which rapidly solidified. Crystallisation from ethyl alcohol furnished pure 3 : 4 : 6-*triacetyl*-2-*methyl* β-*ethylglucoside* in needles, m. p. 95—96° (Found: C, 51·9; H, 6·95; OMe + OEt, 21·55. $C_{15}H_{24}O_9$ requires C, 52·05; H, 6·7; OMe + OEt, 21·9%). $[\alpha]_D$

ethyl alcohol ($c = 1{\cdot}01$). This glucoside is soluble in benzene, acetone, carbon tetrachloride, and chloroform and moderately easily soluble in cold ethyl alcohol; it is less readily soluble in light petroleum (b. p. 40—60°), from which it crystallises in slender needles.

2-Methyl β-ethylglucoside was obtained as a syrup by removal of the solvent from the product of the action of alcoholic ammonia on triacetyl-2-methyl β-ethylglucoside.

Hydrolysis of 2-methyl β-ethylglucoside with 0·7*N*-hydrochloric acid at 95° for 25 hours, followed by evaporation under diminished pressure after removal of the hydrochloric acid by addition of silver carbonate, gave 2-methyl glucose as a gum containing α- and β-forms. It was characterised by its *phenylhydrazone*, m. p. 175—176° (Found: N, 9·4. $C_{13}H_{20}O_5N_2$ requires N, 9·9%).

2-Methyl glucose was also prepared from β-methyl 3 : 4 : 6-triacetyl glucose by methylation with methyl iodide and silver oxide, followed by deacetylation and hydrolysis. A detailed description of this sugar and its derivatives will be given in a later communication.

With iso*Propyl Alcohol. Formation of* 3 : 4 : 6-*Triacetyl* β-iso-*Propylglucoside.*—Evaporation of a solution of the anhydride in *iso*propyl alcohol which had been kept for several hours gave 3 : 4 : 6-triacetyl β-*iso*propylglucoside. It crystallised only slowly and on acetylation with acetic anhydride in pyridine solution yielded 2 : 3 : 4 : 6-*tetra-acetyl* β-iso*propylglucoside*, which separated from alcohol in needles, m. p. 134—135° (Found: C, 52·3; H, 6·8. $C_{17}H_{26}O_{10}$ requires C, 52·3; H, 6·7%). $[\alpha]_D$ − 23·4° in alcohol. The tetra-acetyl glucoside is sparingly soluble in water and only moderately easily soluble in cold ethyl alcohol.

With Benzyl Alcohol. Formation of 3 : 4 : 6-*Triacetyl* β-*Benzyl-glucoside.*—3 : 4 : 6-Triacetyl glucose 1 : 2-anhydride was heated at 100° with benzyl alcohol. After 2 hours, the excess of alcohol was removed under diminished pressure at 100°. The residual 3 : 4 : 6-triacetyl benzylglucoside, after being washed with light petroleum, was converted into β-benzylglucoside, m. p. 119°, $[\alpha]_D$ − 49°, by the action of alcoholic ammonia.

Acetylation of the benzylglucoside yielded 2 : 3 : 4 : 6-tetra-acetyl β-benzylglucoside, m. p. 98—99°, $[\alpha]_D$ − 44° in alcohol (Found: C, 57·5; H, 6·0. Calc.: C, 57·7; H, 6·0%). Fischer and Helferich (*Annalen*, 1911, **383**, 68) give m. p. 96—101° (corr.), $[\alpha]_D$ − 48°.

With Menthol. Formation of 3 : 4 : 6-*Triacetyl* β-*Menthylglucoside.*—The anhydro-compound was heated with an equal weight of benzene and three times its weight of menthol at 90—100° for 30 hours. The excess of menthol was removed under diminished pressure at 100°, leaving a residue of 3 : 4 : 6-triacetyl menthylglucoside. A

filtered solution in ether, on treatment with light petroleum, gave triacetyl menthylglucoside, which was crystallised from carbon tetrachloride or alcohol; m. p. 144° after sintering at 141°, $[\alpha]_D$ − 10·6° in benzene. β-Menthylglucoside was obtained conveniently from the triacetyl glucoside by the action of aqueous-alcoholic potassium hydroxide. Fischer and Bergmann (*Ber.*, 1917, **50**, 711) describe a triacetyl β-menthylglucoside having m. p. 143—146°, and $[\alpha]_D$ − 12·6° in benzene.

With Phenol. Formation of 3 : 4 : 6-*Triacetyl* α-*Phenylglucoside.*—As phenol and the anhydro-compound in benzene reacted only slowly at room temperature, a mixture of phenol with approximately one-third of its weight of 3 : 4 : 6-triacetyl glucose anhydride was maintained at 100° for about 20 hours. After removal of unused phenol at 100° under diminished pressure, the residue of triacetyl phenylglucoside was acetylated in pyridine solution. Crude 2 : 3 : 4 : 6-tetra-acetyl α-phenylglucoside, m. p. 109—110°, resulted, and by one crystallisation from alcohol, the melting point was raised to 112°. This value was not altered by further recrystallisation or by admixture with a genuine specimen of tetra-acetyl α-phenylglucoside. $[\alpha]_D$ + 162° in alcohol (c = 1·0). Fischer and Mechel (*loc. cit.*) give m. p. 115° (corr.), $[\alpha]_D$ + 164·9° in benzene.

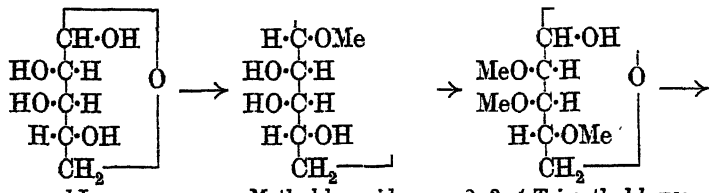
A solution of tetra-acetyl phenylglucoside in twenty times its weight of dry alcohol was saturated with dry ammonia at room temperature and then kept for 15 hours. After removal of the alcohol at 30° in a partial vacuum, and thorough washing with dry ether to remove acetamide, the residue solidified, m. p. 168—169°. Crystallisation from ethyl acetate gave *α-phenylglucoside hydrate*, m. p. 155—160°, $[\alpha]_D$ + 157° in alcohol (Found: C, 52·8; H, 6·7. $C_{12}H_{16}O_6,H_2O$ requires C, 52·5; H, 6·6%).

The author wishes to express his indebtedness to Professor W. N. Haworth, F.R.S., for his interest and his valuable advice.

UNIVERSITY OF BIRMINGHAM,
EDGBASTON. [*Received, October 6th*, 1928.]

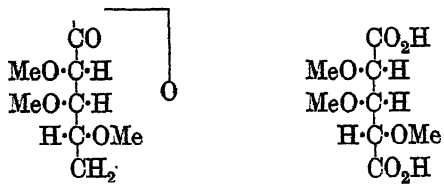
CCCCXVI.—*The Structure of the Normal Monosaccharides. Part V. Lyxose.*

By EDMUND LANGLEY HIRST and JAMES ANDREW BUCHAN SMITH.



IT has been shown (J., 1923, **123**, 1352 and subsequent papers) that when the normal trimethyl derivatives of xylose, arabinose, and rhamnose are oxidised by nitric acid the reaction leads in each case

to the formation of a trimethoxyglutaric acid. This implies that in each of these three trimethyl pentoses the methoxyl groups are attached to the second, third, and fourth carbon atoms, and that the oxygen of the ring must be attached to the fifth carbon atom. The normal trimethyl pentoses are known to possess the same oxide ring structure as the corresponding normal methyl-pentosides, and it follows, therefore, that the normal forms of methylxyloside, methylarabinoside, and methylrhamnoside contain the amylene-oxide ring and belong to the pyranose group of sugar compounds.



Similar experimental methods have been now applied to determine the structure of α-methyl-lyxoside and definite proof has been obtained that this substance and its derivatives are of the pyranose type and thus conform to the general rule followed by normal sugar derivatives. Moreover, in view of the optical relationships which exist between the α-form of lyxose and α-methyl-lyxoside (Phelps and Hudson, *J. Amer. Chem. Soc.*, 1926, **48**, 503), this variety at least of the free sugar may be presumed to possess the pyranose structure. An examination of the structural relationships which exist between the α- and β-modifications of lyxose has been contributed in an earlier paper (Haworth and Hirst, this vol., p. 1221).

The normal trimethyl lyxose required for the oxidation experiments was prepared by methylating crystalline α-methyl-lyxoside with Purdie's reagents. This method of preparation ensures the formation of a *trimethyl methyl-lyxoside*, retaining the oxide ring structure of the original α-methyl-lyxoside. Other experiments showed that the same pyranose form of trimethyl methyl-lyxoside was produced by the direct methylation of lyxose with methyl sulphate. Hydrolysis of the trimethyl methyl-lyxoside gave crystalline *trimethyl lyxose*, m. p. 79°. The constitution of this substance as 2 : 3 : 4-trimethyl lyxose followed at once from a study of its oxidation by nitric acid, and also from the nature of the *trimethyl-lyxonolactone* obtained from it by the action of bromine water. The lactone, which was characterised by the preparation of the corresponding crystalline *phenylhydrazide*, m. p. 180—181°, displayed the behaviour typical of a δ-lactone. Polarimetric observations during its hydrolysis in aqueous solution showed that equilibrium was attained in about 60 hours, and that some 9% of the lactone then remained unchanged. When oxidised with nitric acid the lactone gave exclusively *d*-trimethoxyglutaric acid, which was identified both as the crystalline amide, the enantiomorph of which was originally prepared from *l*-arabinose (Hirst and Robertson, J., 1925, **127**, 358), and as the methylamide (Goodyear

and Haworth, J., 1927, 3145; see also Haworth and Jones, *ibid.*, p. 2349).

d-Lyxose. α-Methyl-lyxoside. 2 : 3 : 4-Trimethyl lyxose.

Trimethyl-δ-lyxonolactone. *d*-Trimethoxyglutaric acid.

These results were in themselves sufficient to warrant the allocation of the pyranose structure to α-methyl-lyxoside, but in order to render the evidence as strong as possible, experiments were made to determine the effect of nitric acid on trimethyl methyl-lyxoside. The product of the reaction was again *d*-trimethoxyglutaric acid, the pure distilled methyl ester of which was obtained in yields corresponding to 80% of the theoretical. From the ester 88% of the theoretical quantity of pure crystalline *d*-trimethoxyglutaramide was isolated. Since the methylation of methyl-lyxoside proceeded almost quantitatively, it follows that by this method, in spite of the lengthy series of operations involved, some 70% of the calculated quantity of *d*-trimethoxyglutaramide can be obtained from methyl-lyxoside. Control experiments have shown that, under the experimental conditions adopted, nitric acid is without appreciable effect on the products of oxidation, and no product other than trimethoxyglutaric acid could be detected in the present case. In none of the numerous investigations in which this mode of oxidation has been employed has there been any sign of the migration of methoxy-groups under the influence of nitric acid, and the results obtained are both mutually consistent and in agreement with the evidence furnished by independent chemical methods of examination.

Emphasis is laid on the foregoing considerations in view of the total disagreement which exists between the conclusions now drawn from the chemical evidence and the views of Phelps and Hudson (*loc. cit.*), who assign to α-methyl-lyxoside and its derivatives a butylene-oxide formula. These authors have compared the mole-

cular rotations of the two pairs of epimeric substances α-methyl-lyxoside and α-methylxyloside, and α-methylmannoside and α-methyl-glucoside. They find between each pair a difference in $[M]_D$ of about 15,500 units, which is taken to indicate the existence of similar structural relationships between the members of each pair, a conclusion with which the experimental results now presented are in complete agreement. Since, however, they regard α-methylxyloside and α-methylmannoside as 1 : 5-oxides and α-methylglucoside as a 1 : 4-oxide, it is argued that α-methyl-lyxoside must be similar in structure to α-methylglucoside and therefore a 1 : 4-oxide. In a later paper (*J. Amer. Chem. Soc.*, 1928, **50**, 2049) they reach similar conclusions from a study of the rotations of the acetylated derivatives of these four methyl-glycosides, the α-methylglucoside used for comparison being now the hypothetical 1 : 5-compound whose rotation has been calculated by Hudson. It is obvious that the validity of this mode of reasoning is dependent on the certainty with which the furanose structure can be assigned to α-methylglucoside and the pyranose structure to its hypothetical isomeride. It will be remembered that as a basis for the argument used in demonstrating the presence of a 1 : 4-ring in α-methylglucoside Hudson (*J. Amer. Chem. Soc.*, 1926, **48**, 1424, 1434) accepted the pyranose structure of α-methylxyloside and of α-methylarabinoside on the ground that it had been established experimentally by oxidation methods. It is evident, therefore, that experiments of a precisely similar nature carried out with α-methyl-lyxoside would provide a critical test of the accuracy of the optical method in assigning ring structures. These experiments have now been performed, and the results permit of no reasonable interpretation other than that α-methyl-lyxoside possesses a pyranose structure. A furanose structure was, however, deduced from the optical data and an obvious inconsistency is thus made manifest, which can be removed most simply by accepting the chemical evidence for the pyranose structure of α-methyl-glucoside. If this be done, the optical relationships existing between the four methylglycosides considered by Phelps and Hudson then agree with the chemical evidence in supporting the pyranose structure of all these compounds. It thus follows that the observations now recorded lend additional support to the reasons which have already been advanced (Drew and Haworth, J., 1926, 2303; Haworth and Hirst, *loc. cit.*) for doubting the validity of certain assumptions made by Hudson in deducing the furanose structure of α-methyl-glucoside.

EXPERIMENTAL.

Trimethyl Methyl-lyxoside.—Crystalline methyl-lyxoside (m. p. 109°) (7·2 g.) was dissolved in methyl iodide (20 c.c.) and treated

with silver oxide (35 g.) in the usual manner. After the fourth successive methylation under these conditions the product was distilled, giving *trimethyl methyl-lyxoside* as a colourless mobile oil (8·7 g.), b. p. about 70°/0·02 mm., $n_D^{14°}$ 1·4460, $[\alpha]_{5461}^{20°}$ + 10° in water ($c = 2·61$), $[\alpha]_{5461}^{20°}$ + 37·3° in alcohol ($c = 4·05$). The substance, which possessed typical glucosidic properties, resisted all attempts to crystallise it. The absence of oxidation products in the form of lactones or esters was proved by heating a weighed portion (0·196 g.) for 30 minutes with 5 c.c. of *N*/10-sodium hydroxide, 5 c.c. of *N*/10-sulphuric acid being then required to titrate the remaining alkali. The mode of preparation and its specific rotation indicated that the trimethyl methyl-lyxoside consisted largely of the α-isomeride (Found: C, 51·8; H, 8·7; OMe, 58·8. $C_9H_{18}O_5$ requires C, 52·4; H, 8·7; OMe, 60·2%).

Trimethyl Lyxose.—Trimethyl methyl-lyxoside (4·0 g.) was hydrolysed by heating it at 100° with 6% aqueous hydrochloric acid (120 c.c.). In the course of one hour the specific rotation altered from $[\alpha]_{5461}^{20°}$ + 7° to a constant value $[\alpha]_{5461}^{20°}$ — 19°. The hydrochloric acid was then neutralised with barium carbonate and the *trimethyl lyxose* was extracted from the solution by chloroform. The product (3·6 g.) was distilled, giving a mobile, colourless liquid, (3·3 g.), b.p. 90°/0·05 mm., $n_D^{15°}$ 1·4629. After being kept for 12 hours, the distillate became viscid and finally set to a solid glass, which crystallised when rubbed. In subsequent experiments the distillation was omitted and the trimethyl lyxose crystallised when nucleated (yield, 85%). Recrystallisation from light petroleum gave trimethyl lyxose in long needles, m. p. 79°, $[\alpha]_D^{20°}$ — 22° in water (equilibrium value; $c = 2·01$) (Found: C, 50·0; H, 8·4; OMe, 48·2. $C_8H_{16}O_5$ requires C, 50·0; H, 8·3; OMe, 48·4%).

The mutarotation of normal trimethyl lyxose was rapid in aqueous solution, the equilibrium value being reached in less than 30 minutes at 21°. The following table gives the details of a typical experiment ($c = 2·01$).

Time (mins.)	1·5	3·3	4·3	6·0	7·8	10·0
$[\alpha]_D^{21°}$	−11·9°	13·4°	14·4°	14·9°	15·9°	17·4°
Time (mins.)	11·8	15	20	28	250	
$[\alpha]_D^{21°}$	17·8°	19·4°	21°	21·8°	21·8°	

From these figures the initial rotation was calculated to be $[\alpha]_D^{21}$ — 10°, and the mean value for $k_1 + k_2$ was found to be 0·045 (t in mins.). Observations were made of the specific rotation in methyl alcohol containing 1% of hydrogen chloride before and after heating the solution. The values were respectively $[\alpha]_D^{20°}$ — 7·1° (c = 0·72) and $[\alpha]_D^{20°}$ + 21° ($c = 0·83$). In the latter case the concentration is that of the trimethyl methyl-lyxoside formed during the reaction

and the observation gives the specific rotation of the equilibrium mixture of the α- and β-isomerides of normal trimethyl methyl-lyxoside.

Methylation of Lyxose with Methyl Sulphate.—Lyxose (10 g.), dissolved in the least possible amount of water, was treated with methyl sulphate (76 c.c.) and 50% aqueous sodium hydroxide solution (140 c.c.), the usual precautions being taken. The product (12 g.) was then subjected to two successive methylations with methyl iodide and silver oxide. On distillation, trimethyl methyl-lyxoside was obtained as a colourless oil (10·6 g.), b. p. about 70°/0·02 mm., $n_D^{14°}$ 1·4471, $[\alpha]_D^{20°}$ — 6° in methyl alcohol ($c = 1·44$). After being heated with methyl alcohol containing 1% of hydrogen chloride, the trimethyl methyl-lyxoside gave as the equilibrium value $[\alpha]_D^{20°}$ + 20·6°. The trimethyl methyl-lyxoside prepared in this manner therefore contained excess of the β-isomeride, and gave the same equilibrium value for the specific rotation as normal trimethyl methyl-lyxoside (Found: OMe, 58·8. Calc.: OMe, 60·2%). Further evidence confirming the absence of the furanose isomeride was obtained in the following way. During hydrolysis with 6% aqueous hydrochloric acid, the rotation of the solution changed to $[\alpha]_D^{20°}$ — 22° (calculated as trimethyl lyxose), which is very near to the value recorded for normal trimethyl lyxose, and the yield of crystalline trimethyl lyxose, m. p. 79°, isolated after hydrolysis was 90% of the theoretical.

Trimethyl-lyxonolactone.—A solution of trimethyl lyxose (9 g.) in water (60 c.c.) was treated with bromine (8—10 c.c.), the bromine being added gradually and the temperature maintained at 35° until the reducing properties of the solution had disappeared. This required several days, after which the excess of bromine was removed by aëration. The solution was then neutralised with silver oxide and filtered and the dissolved silver was removed as silver chloride by addition of the exact quantity of hydrochloric acid, the end-point being determined with the aid of Congo-paper. The water was then removed under diminished pressure. The residual syrup was heated at 100°/12 mm. for some hours to complete lactonisation and was then distilled, giving *trimethyl-δ-lyxonolactone* as a liquid, b. p. 105°/0·02 mm., $n_D^{18°}$ 1·4620 (yield, 8·0 g.). $[\alpha]_D^{18°}$ + 35·5° (initial value); $[\alpha]_D^{18°}$ — 9·3° (equilibrium value), both in water ($c = 1·2$) (Found: C, 50·3; H, 7·4; OMe, 49·1. $C_8H_{14}O_5$ requires C, 50·5; H, 7·4; OMe, 48·9%). 0·1232 G. of the substance required 7·0 c.c. of N/10-sodium hydroxide for neutralisation (calc., 6·9 c.c.).

The lactone, although analytically pure, could not be made to crystallise. When, however, it was heated on the water-bath with

the exact quantity of phenylhydrazine dissolved in a little ether, it readily formed the crystalline phenylhydrazide of the corresponding acid. The solid product (yield 80%), after being washed with ether, was found to be the pure *phenylhydrazide* of 2 : 3 : 4-trimethyl-lyxonic acid, m. p. 180—181°, remaining unaltered after two recrystallisations from benzene (Found: C, 56·5; H, 7·7; N, 9·6; OMe, 30·9. $C_{14}H_{22}O_5N_2$ requires C, 56·3; H, 7·4; N, 9·4; OMe, 31·2%).

Attempts to obtain the lactone in a crystalline condition by regenerating it from the crystalline phenylhydrazide yielded material identical with that described above.

Hydrolysis of the lactone. The velocity of hydrolysis in aqueous solution was determined by polarimetric observation, the mean value for $k_1 + k_2$ being 0·027 at 19° (t in hours). Equilibrium was reached in about 3 days at 19°. The rotation of the corresponding acid was obtained in the following manner. A weighed amount of the lactone was dissolved in excess of standard sodium hydroxide solution. The exact amount of sulphuric acid equivalent to the alkali was added, and the rotation was observed immediately; $[\alpha]_D^{19°}$ — 13·4° (calc. as lactone). The proportion of lactone present at equilibrium was therefore 9·1%.

t (hrs.).	$[\alpha]_D^{19°}$.	% Lactone.	t (hrs.).	$[\alpha]_D^{19°}$.	% Lactone.
0	+35·5°	100	51·5	−7·7°	12·4
18·0	5·1	38·3	66·5	9·3	9·1
27·8	− 0·8	26·4	90·5	9·3	9·1
42·5	6·1	15·6	200	9·3	9·1

Oxidation of Trimethyl-lyxonolactone.—A solution of the lactone (1·6 g.) in nitric acid (d 1·42; 25 c.c.) was heated gently on the water-bath until the vigorous reaction had ended, and then for 1½ hours at 90°. The nitric acid was removed by distillation under diminished pressure, and the syrupy residue boiled for 5 hours with 3% methyl-alcoholic hydrogen chloride (25 c.c.). The solution, after being neutralised with silver oxide, was evaporated to a syrup, which gave on distillation methyl trimethoxyglutarate (1·6 g., or 76% of the theoretical), b. p. about 100°/0·1 mm., $n_D^{21°}$ 1·4353, $[\alpha]_D^{20°}$ — 39° in methyl alcohol ($c = 0·4$), $[\alpha]_D^{20}$ — 31° in water ($c = 1·51$) (Found: OMe, 59·0; CO_2Me, by titration, 46·2. Calc.: OMe, 62·0; CO_2Me, 47·2%). Treatment of the ester with methyl-alcoholic ammonia gave trimethoxyglutaramide, m. p. 230° (decomp.), $[\alpha]_D^{20°}$ — 49° in water ($c = 0·7$). Methyl-alcoholic methylamine gave similarly the methylamide, m. p. 171—172° alone or when mixed with a specimen of the methylamide of trimethoxyglutaric acid obtainable from tetramethyl-δ-ma[illegible] lactone (Goodyear and Haworth, *loc. cit.*). The high yields [illegible]

amide and methylamide (in each case, more than 70% of the theoretical) served to prove the homogeneity of the liquid ester.

Additional oxidation experiments were performed in order to determine the largest possible yields of crystalline trimethoxyglutaramide obtainable from α-methyl-lyxoside. For this purpose trimethyl methyl-lyxoside (prepared as above from α-methyl-lyxoside) was heated with nitric acid (*d* 1·42) under conditions exactly similar to those given above for the oxidation of the trimethyl-lyxonolactone. In this way 1·6 g. of trimethyl methyl-lyxoside gave 1·7 g. of distilled methyl trimethoxyglutarate, $n_D^{20°}$ 1·4355, $[\alpha]_D^{20°}$ — 34° in water ($c = 1·3$).

The values now recorded of $[\alpha]_D^{20°}$ for methyl trimethoxyglutarate are regarded as more nearly correct than those given in earlier papers (compare Hirst and Robertson, *loc. cit.*; McOwan, J., 1926, 1747). Dilute nitric acid was used in the previous work and it is probable that the ester then obtained contained a little trimethyl-δ-arabonolactone, insufficient in amount to affect the analyses but sufficient, owing to the exceedingly large rotation of the lactone, to affect the observed rotation value. That no racemisation or structural change has occurred in the present experiment is proved by the fact that nearly theoretical yields (88%) of the crystalline amide, m. p. 230° (decomp.), were obtained when the ester was treated with methyl-alcoholic ammonia. The specific rotation of this amide, $[\alpha]_D^{20°}$ — 49° in water ($c = 0·9$), agreed exactly with the observations previously recorded. The overall yield of amide from α-methyl-lyxoside was therefore 70%. The corresponding methylamide, m. p. 171—172°, was also prepared from the ester (yield 80%).

The authors wish to thank Professor W. N. Haworth, D.Sc., F.R.S., for his interest in this work, and one of them (J. A. B. S.) desires to express his gratitude to the Department of Scientific and Industrial Research for the award of a maintenance grant, and to the Chemical Society for a grant which has in part defrayed the cost of the experiments.

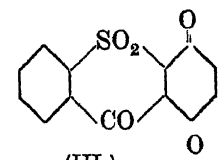
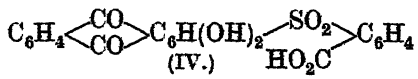
CCCCXVII.—*Hydroxy-derivatives of Thioxanthone Dioxide.*

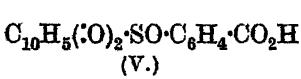


By WILLIAM BENNETT PRICE and SAMUEL SMILES.

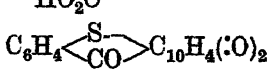
DURING an examination of the abnormal properties of 1-methoxy- and 1-hydroxy-thioxanthones a comparison with the corresponding sulphones was desirable. The only method hitherto used for the



preparation of substituted thioxanthone dioxides is the oxidation of the corresponding thioxanthone with hydrogen peroxide or similar agents (Ullmann and Glenck, *Ber.*, 1916, **49**, 2491). This process is generally valuable, but the application to hydroxythioxanthones is not always successful, particularly in the case of 1 : 4-dihydroxy-derivatives. An effective process leading to the 1 : 4-dihydroxythioxanthone dioxide and certain of its derivatives has been found in the action of 2-sulphinobenzoic acid upon *p*-benzoquinones. In accordance with the general behaviour of sulphinic acids with quinones (Hinsberg, *Ber.*, 1894, **27**, 3259) 2 : 5-*dihydroxydiphenylsulphone-2'-carboxylic acid* (I) was obtained which by dehydration yielded the thioxanthone dioxide (II).



(I.)

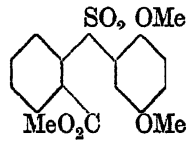


(II.)

(III.)

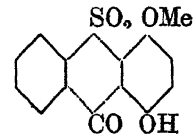
The interesting quinone (III) was isolated when this 1 : 4-dihydroxy-derivative was oxidised with lead tetra-acetate. The union of 2-sulphinobenzoic acid with simple *p*-quinones such as toluquinone and chlorobenzoquinone took place easily and even with quinizarinquinone the substituted phenylanthraquinonylsulphone (IV) was obtained, but in this case dehydration yielding the thioxanthone dioxide could not be effected. Union of 1 : 2-naphthaquinone and this sulphinic acid did not take place in the normal manner, but gave an unstable additive product containing an additional molecule of water. Dehydration of this material by heating it alone or in solvents removed water (2 mols.) and gave a product which is to be regarded as the sulphoxide (V) derived from 1 : 2-naphthaquinone, since it yielded a phenylhydrazone and a phenazine and on being heated with acetic anhydride gave the naphthathioxanthonequinone (VI).

(IV.)



(V.)

(VI.)



The 2-thiobenzoic group could be easily removed from this primary additive product by reduction, whereas this group in the sulphoxide quinone (V) was relatively stable to mild reducing agents. For these reasons it is suggested that the primary product of reaction between 1 : 2-naphthaquinone and 2-sulphinobenzoic acid is best represented by the structure (VII), the sulphinic acid reacting in the

tautomeric hydroxy-form R·SO·OH. This case is evidently similar to that encountered by Hinsberg (*Ber.*, 1919, **52**, 28) in the union of 1 : 4-naphthaquinone with naphthalene-1-sulphinic acid. Hinsberg isolated from these reagents an additive product which under the action of heat lost water and was converted into the sulphoxide (compare V) derived from 1 : 4-naphthaquinone. It was thought that this abnormal behaviour of naphthalene-1-sulphinic acid and of 2-sulphinobenzoic acid might be associated with the ortho-substituent contained by them, but preliminary experiments with other ortho-substituted sulphinic acids and 1 : 2-naphthaquinone have given the usual type of sulphone. Further investigation of the necessary conditions is being made.

(VII.)

(VIII.)

(IX.)

In a study of the methylation of these hydroxythioxanthone dioxides in alkaline media the usual inhibitory effect of the ortho-carbonyl group was observed in the 1-hydroxy-derivatives. For instance, the *2-methoxy-* and *2 : 3-dimethoxy-thioxanthone dioxides* were easily obtained from the hydroxy-compounds by this method, but the 1 : 4-dihydroxy-derivative (II) was only slightly attacked even under intense conditions, the chief product being then *1-hydroxy-4-methoxythioxanthone dioxide* (IX). The ortho-sulphonyl group does not exert this inhibitory effect in alkaline methylation. For example, *p*-cresol-*o*-sulphone was rapidly alkylated and 2 : 5-dihydroxydiphenylsulphone-2'-carboxylic acid (I) gave almost theoretical yields of the *ester* (VIII). Similar results were obtained with other hydroxy-sulphones.

Experimental.

When equimolecular quantities of 2-sulphinobenzoic acid and *p*-benzoquinone or its simple derivatives were shaken with water (100 c.c. : 2 g. of reagents) reaction was complete in 1—2 hours. A small quantity of tarry material was usually formed; this was removed and the desired product, which separated from the liquid, was collected. The following are examples of hydroxy-derivatives of diphenylsulphone obtained by this method. *2 : 5-Dihydroxydiphenylsulphone-2'-carboxylic acid* (I), from *p*-benzoquinone and 2-sulphinobenzoic acid, formed prisms, m. p. 235° (Found : C, 53·0; H, 3·6; S, 10·8. $C_{13}H_{10}O_6S$ requires C, 53·0; H, 3·4; S, 10·8%). The *diacetyl* derivative, needles from acetic acid, had

m. p. 188° (Found: C, 53·9; H, 3·8. $C_{17}H_{14}O_8S$ requires C, 53·9; H, 3·7%). When methyl sulphate (5 mols.) was added to a hot solution of this dihydroxy-acid (1 mol.) in aqueous sodium hydroxide (6 mols.) an almost theoretical yield of *methyl* 2 : 5-*dimethoxydiphenylsulphone-2'-carboxylate* (VIII), m. p. 195°, separated (Found: C, 57·1; H, 4·7. $C_{16}H_{16}O_6S$ requires C, 57·1; H, 4·7%). Hydrolysis of this ester yielded 2 : 5-*dimethoxydiphenylsulphone-2'-carboxylic acid*, which separated in plates, m. p. 223°, from acetic acid (Found: C, 55·7; H, 4·2. $C_{15}H_{14}O_6S$ requires C, 55·9; H, 4·3%).

Methyl-2 : 5-*dihydroxydiphenylsulphone-2'-carboxylic acid*, from 2-sulphinobenzoic acid and *p*-toluquinone, formed needles, m. p. 203° (Found: C, 54·4; H, 3·8. $C_{14}H_{12}O_6S$ requires C, 54·5; H, 3·9%).

Chloro-2 : 5-*dihydroxydiphenylsulphone-2'-carboxylic acid*, from chlorobenzoquinone and the sulphinic acid, separated from acetic acid in fine needles, m. p. 210° (Found: C, 47·4; H, 2·8. $C_{13}H_9O_6ClS$ requires C, 47·4; H, 2·7%). Sulphones of this type which form an intermediate stage in the synthesis of thioxanthone dioxides may also be obtained by oxidation of the corresponding sulphides, these being available from the reaction of phenols with the dichloride of 2-sulphinobenzoic acid (this vol., p. 2859). In certain cases this alternative may not be available. For example, when 2 : 4-dihydroxy-2'-carboxydiphenyl sulphide (this vol., p. 2862) was treated in the usual manner with hydrogen peroxide or similar agents the required sulphone could not be isolated, and restricted action of hydrogen peroxide led to 2 : 4-*dihydroxy-2'-carboxydiphenyl sulphoxide*, $C_6H_3(OH)_2{\cdot}SO{\cdot}C_6H_4{\cdot}CO_2H$, which gave a purple solution with sulphuric acid and had m. p. 204° (Found: C, 56·3; H, 3·7. $C_{13}H_{10}O_5S$ requires C, 56·1; H, 3·6%). This did not yield the corresponding thioxanthone with the usual dehydrating agents.

2-*Quinizarinphenylsulphone-2'-carboxylic Acid* (IV).—Acetic acid (20 c.c.; 1 g. of reagents) containing equal weights of quinizarin-quinone and the sulphinic acid was boiled until separation of the products began. The *sulphone* was collected from the cooled liquid and purified from nitrobenzene; it formed red needles, m. p. 263°, and gave a blue solution in aqueous alkali hydroxide (Found: C, 59·2; H, 2·9. $C_{21}H_{12}O_8S$ requires C, 59·4; H, 2·8%).

Derivatives of Thioxanthone Dioxide.—Condensation of the 2-carboxy-derivatives of diphenylsulphone was effected by heating (100°) the solutions in sulphuric acid for varying periods, the progress of the reaction being indicated by the development of the intense red colour due to the thioxanthone dioxide. The products were isolated after addition of ice.

1 : 4-*Dihydroxythioxanthone dioxide* (II) separated from acetic acid in orange needles, m. p. 224°, which gave a crimson solution in

aqueous alkali (Found : C, 56·2; H, 3·0. $C_{13}H_8O_5S$ requires C, 56·5; H, 2·9%). The *diacetyl* derivative separated from alcohol in yellow needles, m. p. 174° (Found : C, 56·7; H, 3·3. $C_{17}H_{12}O_7S$ requires C, 56·6; H, 3·3%).

Methyl-1 : 4-*dihydroxythioxanthone dioxide* formed orange plates, m. p. 175°, from acetic acid (Found : C, 57·5; H, 3·7. $C_{14}H_{10}O_5S$ requires C, 57·9; H, 3·4%).

Chloro-1 : 4-*dihydroxythioxanthone dioxide* was obtained in similar form, m. p. 230° (Found : C, 50·3; H, 2·5. $C_{13}H_7O_5ClS$ requires C, 50·2; H, 2·2%).

Thioxanthone Dioxide 1 : 4-*Quinone* (III).—A thin paste of the 1 : 4-dihydroxy-derivative (2 g.) and acetic acid was triturated with lead tetra-acetate (4 g.). After 4 days the solid was collected and purified from benzene. The desired product was thus obtained in yellow needles, m. p. 185°, which liberated iodine from aqueous potassium iodide (Found : C, 56·7; H, 2·2. $C_{13}H_6O_5S$ requires C, 56·9; H, 2·2%).

1 : 4-*Dimethoxythioxanthone dioxide* was obtained either by oxidation of 1 : 4-dimethoxythioxanthone (Clarke and Smiles, J., 1911, **99**, 1535) with hydrogen peroxide in warm acetic acid or by heating 2 : 5-dimethoxydiphenylsulphone-2′-carboxylic acid or its methyl ester with sulphuric acid. The substance separated from acetic acid in pale yellow needles, m. p. 193° (Found : C, 59·1; H, 4·1. $C_{15}H_{12}O_5S$ requires C, 59·2; H, 3·9%). It is also formed when the dihydroxy-compound is submitted to alkaline methylation, but the yields are poor even under intense conditions. The following experiment is quoted in illustration. The dark red potassium salt of the dihydroxythioxanthone dioxide was heated (130°) for 6 hours with excess of methyl sulphate. After the mixture had been cooled, the excess of the ester was decomposed by aqueous alkali. The dimethyl ether was then obtained (7—8%) from the material unattacked by alkali hydroxide, and from the remainder the 1-hydroxy-4-methoxy-derivative (IX) was isolated by means of the sparingly soluble sodium salt. This monomethyl ether (m. p. 184°) was identified with a sample prepared by another synthesis which will be described in a future communication.

2-*Hydroxythioxanthone Dioxide*.—When phenol and 2-thiolbenzoic acid were dissolved in warm sulphuric acid (Christopher and Smiles, J., 1911, **99**, 2050), or when the product from phenol and the dichloride of 2-sulphinobenzoic acid (this vol., p. 2862) was treated with this solvent, a hydroxythioxanthone was formed which on methylation yielded a methoxythioxanthone identical with the 2-derivative. The constitution of the latter was determined by a synthesis which will be subsequently described.

A solution of this 2-hydroxythioxanthone and excess of hydrogen peroxide in hot acetic acid was kept at 100° during 1 hour. The required *sulphone* then separated in shining yellow needles, m. p. 259° (Found: C, 59·7; H, 3·2. $C_{13}H_8O_4S$ requires C, 60·0; H, 3·0%). *2-Methoxythioxanthone dioxide*, m. p. 204°, was obtained in good yield by alkaline methylation and formed pale yellow plates from acetic acid (Found: C, 61·0; H, 3·6. $C_{14}H_{10}O_4S$ requires C, 61·3; H, 3·6%).

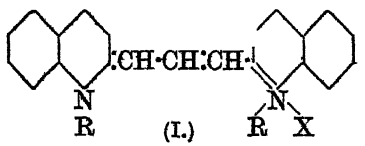
2 : 3-*Dihydroxythioxanthone Dioxide*.—When pyrocatechol was submitted to the same treatments as phenol in the foregoing case, a dihydroxythioxanthone was obtained. It was identical with a sample of the 2 : 3-derivative prepared by another synthesis. When this substance was oxidised in the usual manner the required *sulphone* was obtained in yellow needles, m. p. 203° (decomp.) (Found: C, 56·2; H, 3·1. $C_{13}H_8O_5S$ requires C, 56·5; H, 2·9%). Aqueous alkaline methylation of this material gave good yields of 2 : 3-*dimethoxythioxanthone dioxide*, which formed long, yellow needles, m. p. 241°, from acetone (Found: C, 59·2; H, 4·2. $C_{15}H_{12}O_5S$ requires C, 59·2; H, 3·9%).

Naphthalene Derivatives.—An aqueous solution (400 c.c.) of 2-sulphinobenzoic acid (3·6 g.) was added to a stirred suspension of 1 : 2-naphthaquinone (2·4 g.) in water (50 c.c.). When the quinone had disappeared, the tarry matter was removed from the clear solution, the latter kept for 2 days, and the crystalline product purified from alcohol–water.

The desired *additive product* (VII) was thus obtained in shining plates, m. p. 156° (decomp.), which were sparingly soluble in water and readily soluble in alcohol (Found: C, 56·2; H, 4·2; S, 8·7. $C_{17}H_{12}O_6S,H_2O$ requires C, 56·3; H, 3·9; S, 8·8%). When a solution of this material in 10 times its weight of acetic acid was boiled for 1 hour, 1 : 2-*naphthaquinone 2'-carboxyphenyl sulphoxide* (V) was obtained. This separated from the cooled liquid in red needles, m. p. 236°, which were sparingly soluble in most organic media (Found: C, 62·2; H, 3·3; S, 9·8. $C_{17}H_{10}O_5S$ requires C, 62·6; H, 3·0; S, 9·8%). This quinone yielded, after reaction with phenylhydrazine in acetic acid, a *phenylhydrazone*, m. p. 251° (Found: N, 6·7. $C_{23}H_{16}O_4N_2S$ requires N, 6·7%). Also the *quinoxaline* derivative was obtained by reaction with *o*-phenylenediamine in the usual manner. This formed bright red needles, m. p. 292—293° (Found: C, 69·3; H, 3·8. $C_{23}H_{14}O_3N_2S$ requires C, 69·3; H, 3·5%).

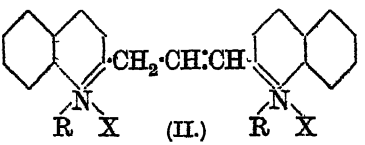
3 : 4-*Naphthathioxanthone*-1 : 2-*quinone* (VI).—When a solution of the naphthaquinone sulphoxide (V) (1 g.) and freshly fused sodium acetate (5 g.) in acetic anhydride (20 c.c.) was boiled (3 hours),

condensation took place. The brown crystalline cake, remaining after the solvent had been decomposed by water, was purified from acetic acid. The *quinone* was then obtained in orange-brown needles with a metallic lustre, m. p. 244—245°, which were insoluble in alkali (Found: C, 69·8; H, 2·9. $C_{17}H_8O_3S$ requires C, 69·8; H, 2·7%).



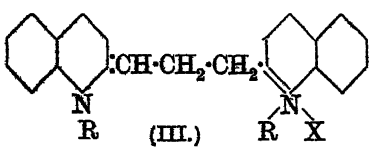
KING'S COLLEGE, LONDON. [*Received, October 26th*, 1928.]

CCCCXVIII.—*Carbocyanine Dyes with Substituents attached to the Three-carbon Chain.*

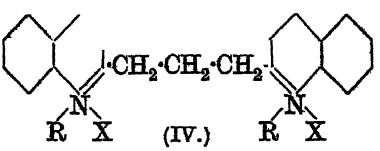


By FRANCES MARY HAMER.

THE carbocyanine dyes are characterised by the three-carbon chain, :CH·CH:CH·, linking two heterocyclic nuclei containing nitrogen, which is tervalent in one nucleus, quinquevalent in the other. By varying the nature of these nuclei, seven types of carbocyanine have been made: 2 : 2′-carbocyanine, 2 : 4′-carbocyanine, 4 : 4′-carbocyanine, thiocarbocyanine, oxacarbocyanine, indocarbocyanine (see Hamer, J., 1927, 2796; Bloch and Hamer, *Phot. J.*, 1928, **68**, 21) and selenocarbocyanine (Clark, this vol., p. 2313), whilst, should the nuclei in a given carbocyanine differ from each other (compare Mills and Raper, J., 1925, **127**, 2466), still other possibilities would arise.



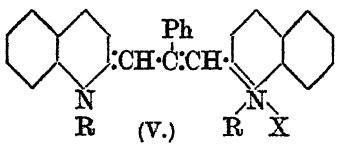
There are only three recorded instances of carbocyanines with substituents attached to the three-carbon chain. The earliest is that of the dinitro-derivative obtained by treatment of a 2 : 2′-carbocyanine with nitric acid (Mills and Hamer, J., 1920, **117**, 1550). To the reason cited in the original paper for considering this to be a substitution and not an addition product of the carbocyanine may be added another, based upon a comparison of the stability relationships of two pairs of compounds. In the case of



(I.)

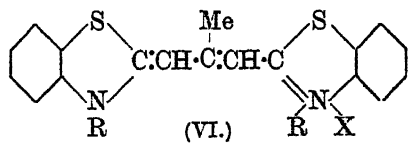
(II.)

(III.)



(IV.)

the first pair, the 2 : 2′-carbocyanine (I) is stable, whilst its monoacid salt (II) is unstable except in the presence of excess of acid. But



with the second pair, the stability relationship is reversed, for the dihydro-derivative (III) of the 2 : 2′-carbocyanine is unknown, whereas the corresponding salts, the methylenediquinaldine dialkylhalides (IV), are stable substances, crystallisable from water (Hamer, J., 1923, **123**, 246). Since the dinitro-compound in question is stable, it is more probably a substitution product of the stable substance (I) than of the unstable dihydro-derivative (III).

Neocyanine is the second instance of a carbocyanine with a substituent attached to the three-carbon chain, since the view has recently been advanced that this dye is a 4 : 4′-carbocyanine in which the hydrogen atom attached to the central carbon of the chain has been replaced by a lepidyl alkylhalide group (Hamer, this vol., p. 1472).

The third case is of especial interest as being a direct synthesis : the carbocyanine (V) was prepared by the action of benzotrichloride on 1-alkyl-2-methylene-1 : 2-dihydroquinoline (Fischer and Rosenhauer, *Z. angew. Chem.*, 1923, **36**, 330; Rosenhauer, with Schmidt and Unger, *Ber.*, 1926, **59**, 2356).

(V.)

(VI.)

The classic method of carbocyanine preparation, by the action of alkali and formaldehyde on an alcoholic solution of a quinaldinium salt in the presence of a quinolinium salt, gives only negative results when acetaldehyde is used instead of formaldehyde, and carbocyanines containing a methyl group as substituent in the chain have been hitherto unknown. The condensation of quaternary salts, which contain reactive methyl groups, with ethyl orthoformate in the presence of pyridine (Hamer, J., 1927, 2796) gives far better yields of carbocyanines than does any other process; it seemed possible that similarly by use of ethyl orthoacetate, which is now readily available (Sah, *J. Amer. Chem. Soc.*, 1928, **50**, 516), there might be synthesised a series of carbocyanines possessing the chain :CH·CMe:CH·.

This hope has only been realised in the case of the thiocarbocyanines, with which the ethyl orthoformate and pyridine method is also most successful. By condensing 1-methylbenzthiazole alkylhalides with ethyl orthoacetate in the presence of pyridine, three new dyes of the general formula (VI) were prepared, the yields of pure products varying from 37—53%. Mr. O. F. Bloch has found that these new dyes, like the unsubstituted thiocarbocyanines (compare Mills, J., 1922, **121**, 455), exert a powerful

photographic sensitising action in the green. Their synthesis provides an additional confirmation of the now well-established constitution of the thiocarbocyanines.

When quinaldine ethiodide, or 1-methylbenzoxazole methiodide, was used instead of 1-methylbenzthiazole alkylhalide, the colour changes indicated the formation of a 2 : 2′-carbocyanine and an oxacarbocyanine respectively, but crystalline products were not isolated; the results were still more unfavourable with lepidine ethiodide and 2 : 3 : 3-trimethylindolenine methiodide.

Experimental.

8-*Methyl*-2 : 2′-*diethylthiocarbocyanine Iodide*.—1-Methylbenzthiazole ethiodide (2 g.; 2 mols.), dry pyridine (20 c.c.), and ethyl orthoacetate (2·4 c.c.; 4 mols.) were boiled together for ½ hour, during which crystals separated. These were filtered off when cold (1·01 g.; 61% yield) and recrystallised from methyl alcohol (150 c.c.); the yield of dye (0·75 g.) was 45%. The yield is much lower when the condensation is carried out in acetic anhydride solution: 21% yield of crude product, 14% after recrystallisation. For analysis, the dye was dried in a vacuum at 100—120° until of constant weight, and this method of drying was also applied to the other two members of the series (Found: C, 52·3; H, 4·7; I, 25·1. $C_{22}H_{23}N_2IS_2$ requires C, 52·15; H, 4·6; I, 25·1%). The dye formed small, copper-coloured crystals, very different from the large, steely prisms of 2 : 2′-diethylthiocarbocyanine iodide. When it was heated, decomposition began at about 280° and melting occurred at about 290°. The spirit solution shows an absorption band at λ 5400 Å. with a much weaker one at λ 5100 Å., whereas for 1 : 1′-diethylthiocarbocyanine iodide the principal band has its maximum at λ 5600 Å. Like 2 : 2′-diethylthiocarbocyanine iodide, the new thiocarbocyanine behaves in a gelatinobromide emulsion as a powerful sensitiser, giving an almost uniform band, which extends to λ 6400 Å. for moderate exposures, and shows maxima at λ 5900 Å. and λ 5200 Å. The sensitising action of the following two dyes is very similar.

2 : 2′ : 8-*Trimethylthiocarbocyanine Iodide*.—The crude substance similarly prepared from 1-methylbenzthiazole methiodide (3 g.) was washed with hot water (1·42 g. obtained; 58% yield) and recrystallised from methyl alcohol (1250 c.c.), in which it was only slightly soluble; the yield after recrystallisation (0·91 g.) was 37% (Found: C, 50·4; H, 4·1; I, 26·4. $C_{20}H_{19}N_2IS_2$ requires C, 50·2; H, 4·0; I, 26·5%). The minute crystals melt at about 298° (decomp.). The principal absorption maximum in spirit solution lies at λ 5400 Å.

8-*Methyl*-2 : 2′-*diallylthiocarbocyanine Bromide*.—Similarly from

1-methylbenzthiazole allobromide (2 g.), pyridine (5 c.c.), and ethyl orthoacetate (2·7 c.c.) was prepared a dye (1·13 g.; 63% yield), which on recrystallisation from methyl alcohol (100 c.c.) was obtained in 53% yield (0·95 g.) (Found: C, 59·7; H, 5·0; Br, 16·7. $C_{24}H_{23}N_2BrS_2$ requires C, 59·6; H, 4·8; Br, 16·5%). The blue crystals melt and decompose at about 260°. The principal absorption maximum in spirit solution is at λ 5450 Å.

CCCCXIX.—*Surface Oxidation of Aluminium, Tungsten, and Molybdenum.*

By LEONARD CHARLES BANNISTER.

VARIOUS investigators have obtained colours on aluminium anodes and ascribed them to interference tints (Zimmermann, *Trans. Amer. Electrochem. Soc.*, 1904, **5**, 147; Mott, *Electrochem. Ind.*, 1904, **2**, 268), and Tammann (*Z. anorg. Chem.*, 1920, **111**, 78; *et seq.*) has used a similar assumption as a basis for much quantitative work on various colours on metals. Moreover, Evans has obtained evidence in support of this view in the cases of films on lead, iron (*Proc. Roy. Soc.*, 1925, *A*, **107**, 234), and copper (J., 1925, **127**, 2484). On the other hand, the sequence of colours obtained on tungsten by anodic treatment has been attributed by Koerner to the formation of different oxides (*Trans. Amer. Electrochem. Soc.*, 1917, **31**, 221). The present paper aims at reconciling the discrepancies in the cases of aluminium and tungsten and describes the extension of the investigation to the case of molybdenum.

EXPERIMENTAL.

In order to determine whether an optical colour sequence was produced, a film varying regularly in thickness was formed on a single piece of each metal in the following way. The metal, abraded with emery, was made the anode, and a platinum wire used as the cathode. The electrolyte was delivered into the cell in a fine jet of solution, filling it up at a slow but uniform rate. At the same time the voltage was steadily decreased, each successive portion of the metal being thus subjected to a different potential. Examination of the dried anodes showed that on aluminium and on tungsten there had been produced a film which displayed a series of colours, each merging into the next as usual in interference colours. In the case of molybdenum, a strip was placed hori-

zontally in the electrolyte between a cathode and an anode of platinum without making metallic contact with them. After the current had passed for a short time, one half of the strip (the cathodic end) was still quite bright, but the other half was covered with a film which increased in thickness from the centre to the end, and produced a series of coloured bands merging into a black deposit. Therefore, under the influence of a potential gradient, the metals will exhibit an appearance similar to that produced on steel by tempering, which is dependent on a heat gradient.

Heat Tinting in Air.—It is difficult, if not impossible, to obtain on aluminium a colour sequence by heating in air. On tungsten, on the other hand, a sequence was produced by heating one end of a strip and so producing a temperature gradient along it. The thickest part of the film consisted of a black powder which turned yellow in parts after prolonged heating at a higher temperature. The films showing first- and second-order colours, irrespective of the method of production, were extremely hard, and resembled the anodic films of aluminium in this respect. They could be scratched with a diamond, but not with a steel blade; they could be removed with emery paper, but all attempts to obtain a quantity of the substance, by scraping it off the metal, failed owing to the minuteness of the deposit.

In order to preserve the heat tints on molybdenum, a strip of the metal was sealed up in a small glass tube and then heated at one end. The partial pressure of the oxide vapour set up within the tube prevented the resulting oxide film from volatilising, as it does when a piece of the metal is heated in the atmosphere.

When strips of freshly cleaned molybdenum were placed in a solution of potassium hydroxide containing dissolved oxygen, or in a solution of an oxidising agent such as potassium chlorate or nitric acid, the surfaces oxidised at rates depending on the temperature and the concentration of the oxidising solution. No visible films could be obtained by immersion in chromic acid, even at higher temperatures, and, incidentally, this treatment made subsequent oxidation by the other methods a slower process, doubtless owing to passivity caused by the presence of a very thin film, which is much more protective than films of interference thickness.

The colours were temporarily diminished in intensity by immersing the metal strips in liquids of high refractive index, showing that the mechanism is not the selective absorption of light.

It was found that if the thickness of a film were reduced to various extents by immersion for definite lengths of time in solvents, the colour also altered.

The foregoing observations lead to only one conclusion, *viz.*, that the film is an oxide film of variable thickness which can cause interference of light in the visible region of the spectrum and so produce colour.

Anodic Treatment.—A comparison is made of colour with voltage of formation (Tables I and II, for aluminium and tungsten, respectively) and with the number of coulombs (Tables III and IV). For aluminium it is possible to calculate the refractive index of the film.

TABLE I.

Anodic treatment of aluminium in $Na_2HPO_4,12H_2O$ (satd.) at 17°.

Voltage.	Colour.
40— 59	Pale yellow.
59— 69	Brown.
69— 77	Red.
77— 85	Purple.
85— 93	Blue.
93—107	Green.
107—120	Yellow.

TABLE II.

Anodic treatment of tungsten in *N*-KCl at 17°.

Voltage.	Colour.
10—21	Yellow.
21—25	Crimson.
25—28	Violet.
28—36	Dark blue.
36—56	Light blue.

TABLE III.

Aluminium (Area of anode, 38·05 sq. cms.).

Coulombs passed.	Thickness of Al_2O_3.	Colour observed.	Approx. wave-length of light missing.	Refractive index.
3·57	0·075 μ	Straw.	0·42 μ	1·73
4·14	0·087 μ	Brown.	0·46 μ	1·60
4·96	0·104 μ	Purple.	0·51 μ	1·59
6·50	0·136 μ	Violet.	0·56 μ	1·52

The values in the fourth column are the wave-lengths of the light complementary to the colour observed. The values obtained for the refractive index are in fairly good agreement with Cauchy's dispersion formula for transparent substances.

TABLE IV.

Tungsten (Area of anode, 4·0 sq. cms.).

Anodic treatment at 143 volts and 16°.

(*a*) In *N*-KCl.				(*b*) In *N*/100-KCl.	
Total coulombs.	Colour.	Total coulombs.	Colour.	Total coulombs.	Colour.
1·48	Yellow.	16·28	Blue.	0·275	Pale yellow.
2·96	Orange.	23·68	Pale green.	0·543	Crimson.
4·44	Purple.	26·64	Green.	0·803	Blue.
5·92	Crimson.	34·04	Deep yellow.	1·056	Light blue.
7·40	Violet.	41·44	Orange.		
11·84	Deep blue.				

Table IV shows that the process of film formation is more efficient when the conductivity of the electrolyte is considerably reduced.

Even if the specific gravity of the film were known, it would not be legitimate to determine the thickness from the amount of electricity passed, for the proportion of current used in film formation seems to vary with the concentration of the electrolyte, hence the refractive index of the film on tungsten is unknown.

The tables given by Koerner clearly indicate that his experiments were not conducted over a sufficiently wide range of conditions to lead to accurate conclusions. The evidence available suggests that the oxide is one lower than WO_3.

The Isolation of the Film.—By the method of Whitey and Millar (*J. Soc. Chem. Ind.*, 1926, **45**, 170T), the films on aluminium were isolated from their metallic base by volatilisation of the latter in a stream of hot hydrogen chloride, special precautions being taken to ensure the absence of traces of water vapour and air during the operation, for otherwise a white, chalky film of alumina was produced. Many of the specimens of film-covered aluminium showed a peculiar inertness towards the attacking gas, but it was observed that the reaction could be initiated by increasing the velocity of the current of gas. Unfortunately, the method was quite unsuccessful in isolating films from tungsten and molybdenum.

The phosphate content of the films was found to vary somewhat: in some, none was detected, and in others it was present up to 6%. It seems probable, therefore, that when phosphate or other acid radical is present, it is merely occluded or held in suspension within the pores of the film. When the films were heated to redness, a loss in weight of 4% took place, which indicates that they consist mainly of oxide with perhaps some water which became sealed within their pores during their growth.

The values for the ratio (Increase of anode weight during treatment)/(Weight of isolated film) were found to be 0·63, 0·58, 0·58, and 0·55 for four different anodes, whereas the theoretical value for O_3/Al_2O_3 is 0·47.

It may be noted that Sutton and Willstrop (*J. Inst. Metals*, 1927, **38**, ii, 259) have analysed the films formed on aluminium by standard anodic treatment in chromic acid, and have found them to consist of the oxide together with a trace of chromate.

The author wishes to thank Prof. W. C. McC. Lewis, F.R.S., by whose kind permission this work was done, Mr. W. J. Shutt, M.Sc., for practical advice, and also Mr. U. R. Evans, M.A., with whom subsequent discussion has been of great value.

CCCCXX.—*Studies of Dynamic Isomerism. Part XXVIII. Absorption Spectra of the Ketonic and Enolic Forms of an α-Diketone.*

By Thomas Martin Lowry, Henri Moureu, and Charles Alexander Hamilton MacConkey.

In the preceding paper of this series (this vol., p. 1333), the statement of Morton and Rosney (J., 1926, 706) that "the isomeric forms of benzoylcamphor give bands of the same wave-length, but of unequal intensity" was shown to be incorrect, since the absorption bands actually occur at different wave-lengths, although they are of very similar intensity, when examined before isomeric change has taken place. Since the preceding statement was used as evidence in support of the general proposition "that enolic and ketonic modifications possess the same wave-length of maximum absorption," it was of interest to see whether this proposition could be substantiated in other cases. In the present investigation, therefore, we have taken advantage of the separation by one of us (Moureu, *Compt. rend.*, 1928, **186**, 380) of the ketonic and enolic forms, (I) and (II), of benzylmethylglyoxal, in order to repeat with an α-diketone the tests that had already been carried out on a typical β-diketone.

$$\underset{\text{(I; ketonic form.)}}{C_6H_5\cdot CH_2\cdot CO\cdot CO\cdot CH_3} \rightleftharpoons \underset{\text{(II; enolic form.)}}{C_6H_5\cdot CH{:}C(OH)\cdot CO\cdot CH_3}$$

The labile ketonic form (I) of benzylmethylglyoxal can be separated in a pure state as a yellow liquid by distillation in presence of a trace of sodium carbonate. Under these conditions, a reversible reaction is produced in the liquid phase, but the more volatile isomeride (which resembles the *o*-quinones in this property) escapes and becomes fixed in the vapour phase by the elimination of the non-volatile catalyst. It therefore distils as a homogeneous product, b. p. 104°/10 mm., and when frozen melts sharply at 17°. On the other hand, when an alkali or a nitrogenous base is added to the liquid, the enolic form (II) crystallises in a pure state, since it is the stable solid phase at all temperatures up to its m. p. at 70°. In the absence of a catalyst, the enol also can be distilled without change, boiling at 134°/10 mm.

The structures of the two isomerides were established by the fact that the yellow quinone-like ketonic form gave no reaction with bromine, reacted but slowly with ferric and antimonous chlorides, and gave only an 18% yield of methane when acted on by the Grignard reagent, whereas the colourless enolic form immediately fixed one molecular proportion of bromine, formed a

salt with ferric chloride and a crystalline derivative with antimonous chloride, and gave an 80% yield of methane with the Grignard reagent (*Compt. rend.*, 1928, **186**, 503).

The measurements set out below show that the absorption bands of the ketonic and enolic forms of the α-diketone differ even more widely than in the case of the stable and labile forms of the β-diketone. In particular, the two adjacent carbonyl groups in the α-diketone displace the familiar ultra-violet band of the simple ketones into the visible region, exactly as in the case of camphorquinone (Lowry and French, J., 1924, **125**, 1921), but without increasing its intensity, whereas the conjugated double bond of the enolic isomeride gives rise to an enormous increase of intensity, but without any important change of wave-length, exactly as in the case of benzylidenecamphor (*ibid.*). The inequality of wave-length is therefore twice as great as in the case of benzoylcamphor, and is accompanied by a difference of intensity in the ratio of about 600 to 1.

The structures assigned to the two isomerides are largely irrelevant to the present discussion, since the general proposition cited above implies that, if a series of isomerides can be converted into one another by successive keto-enol transformations, the wave-length of the absorption bands must remain constant throughout, whatever structure may be assigned to individual members of the series. If, therefore, two isomeric enols can be produced from a given ketone, or if two stereoisomeric enols can be converted into one another through an intermediate ketonic form, as might conceivably occur in the case of benzoylcamphor (*loc. cit.*, p. 1334), the absorption bands of both enols must be at the same wave-length as that of the ketone, and must therefore be identical in wave-length with one another. In the present instance, however, the quinone-like colour of the liquid diketone and the absence of quinonoid characters in the solid isomeride provide an ocular vindication of the structures deduced from the chemical diagnosis recorded above, and make it obvious that we are dealing with a typical keto-enol isomerism.

In view of their close relation to the α-diketone, we have also included in our programme the measurement of the absorption spectra of the compounds set out below.

$C_6H_5\cdot CO\cdot CH_2\cdot CO\cdot CH_3 \rightleftharpoons C_6H_5\cdot C(OH){:}CH\cdot CO\cdot CH_3$

(III; Benzoylacetone, ketonic form.) (IV; Benzoylacetone, enolic form.)

$C_6H_5\cdot CH{:}CH\cdot CO\cdot CH_3$ (V; Benzylideneacetone.)

$C_6H_5\cdot \overset{O}{\overset{\diagup\diagdown}{CH\cdot CH}}\cdot CO\cdot CH_3$ (VI; Acetylphenylethylene oxide.)

Benzoylacetone is a structural isomeride of the α-diketone which

forms the main subject of the present investigation. It exhibits the dual reactivity of a tautomeric compound, yielding derivatives of the ketone (III) and of the enol (IV); but, unlike the isomeric α-diketone, it is only known in one form, to which the structure (IV) is conventionally assigned. The unsaturated ketone (V) has been examined on account of its close relationship to the isomeric enols (II) and (IV). The ethylenic oxide (VI) is a compound of fixed structure, which is isomeric with the labile α- and β-diketones (I) and (III), and the enols (II) and (IV), to which it is related in the same symmetrical manner as the olefin from which it is derived.

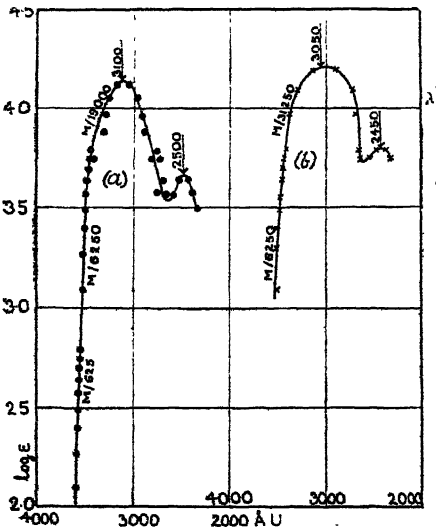

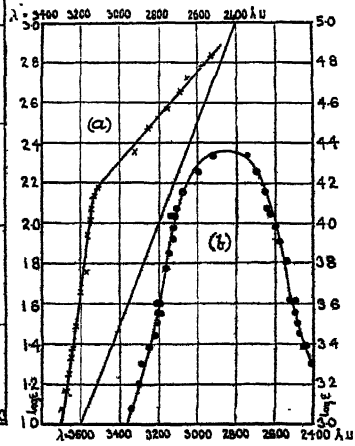

FIG. 2.

(a) *Molecular extinction coefficients of acetylphenylethylene oxide.* (b) *Molecular extinction coefficients of benzylidenacetone.*

1. *Benzoylacetone.*—The absorption spectrum of benzoylacetone has been examined by Baly and Desch (J., 1905, **87**, 766) and by Morgan and Moss (J., 1913, **103**, 78), who recorded the presence of a single absorption band. Our own measurements, with alcohol as the solvent [Fig. 1 (*a*)], gave two maxima

$$\log \varepsilon = 4{\cdot}15 \text{ at } 3100; \quad \log \varepsilon = 3{\cdot}66 \text{ at } 2500 \text{ Å.U.},$$

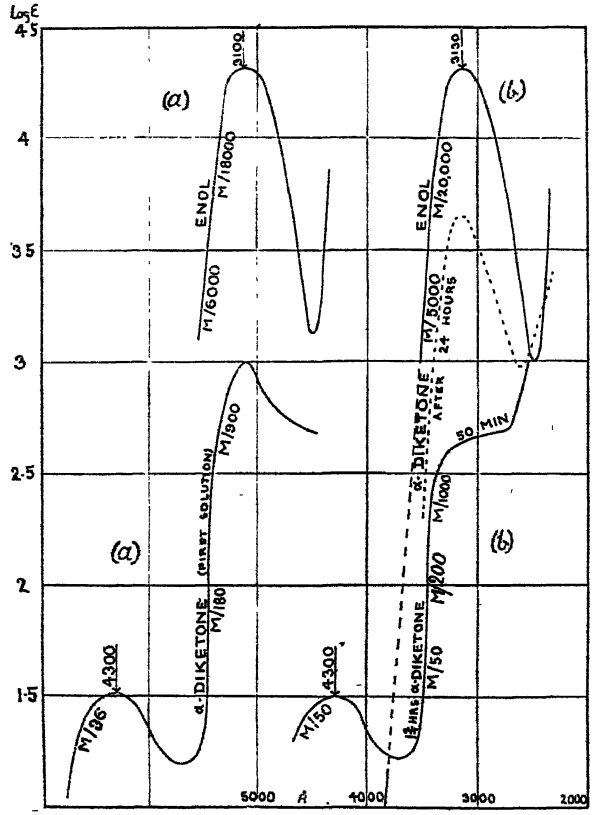
which we had no difficulty in identifying with the characteristic bands of the two forms of benzoylcamphor, *viz.*, $\log \varepsilon = 4{\cdot}27$ at 3140; $\log \varepsilon = 4{\cdot}21$ at 2420 Å.U. No change was observed in the absorption spectrum when examined ½ hour after the pre[illegible]

of the solution and again on the following day. A similar pair of maxima

$$\log \varepsilon = 4{\cdot}26 \text{ at } 3050; \quad \log \varepsilon = 3{\cdot}80 \text{ at } 2450$$

was observed when the experiment was repeated with a freshly-prepared solution in *cyclo*hexane [Fig. 1 (*b*)], the measurements being completed in the course of about 80 minutes.

Since the only known form of benzoylacetone gives an immediate coloration with ferric chloride, it has generally been supposed to have an enolic structure, and the band observed by Baly and Desch, and by Morgan and Moss at 3100 Å.U., has been regarded as a characteristic of the isomeride (IV). If no other information were available, it might be supposed that the two bands shown in Fig. 1 (*a*) and (*b*) were both due to the same isomeride, since we have not been able to observe them separately. On the other hand, the close agreement of the wave-lengths of the bands of Fig. 1 (*a*) with those of alcoholic solutions of the two forms of benzoylcamphor leads us to conclude that in this case also the bands are due to two isomeric forms of the β-diketone; our failure to separate them can then be attributed to catalysis, since we do not yet know of any certain method of arresting isomeric change in these very sensitive prototropic compounds. This conclusion is confirmed by the fact that, whilst the intensity of the bands given by the two pure forms of benzoylcamphor is greater than those of the two bands of benzoylacetone, the latter agree quite well with the intensities of the bands ($\log \varepsilon = 4{\cdot}10$ and 3·90) in an equilibrium mixture of the two forms of benzoylcamphor. According to this view, the crystals of benzoylacetone, melting at 61°, may be regarded as a homogeneous solid phase, probably corresponding in structure with the stable form of benzoylcamphor, but reverting with even greater readiness to an equilibrium mixture in solution.



2. *Benzylideneacetone and Acetylphenylethylene Oxide.*—The absorption spectrum of benzylideneacetone (V) is shown in Fig. 2 (*b*). As might be expected, it gives a maximum, $\log \varepsilon = 4{\cdot}36$ at 2850 Å.U., in close agreement with the maximum ($\log \varepsilon = 4{\cdot}32$ at 2900 Å.U.) already recorded for an alcoholic solution of benzylidenecamphor (Lowry and French, J., 1924, **125**, 1921). The close agreement in the position and intensity of the two bands shows that the influence of the camphor nucleus is not very great, and suggests that the observations made with camphorquinone, benzoylcamphor, and other compounds of the camphor group may be expected to reappear almost unchanged in the corresponding open-chain compounds of the present series.

The absorption spectrum of acetylphenylethylene oxide is shown Fig. 2 (*a*). Unlike the preceding compound, it does not give an

absorption band, but only a rapid " step-out " at wave-lengths less than 3100 Å.U. Since one of the ketonic groups remains intact when we pass from the labile α- or β-diketone to the fixed oxide, it is remarkable that this oxide does not give the familiar ketonic band at about 3000 Å.U. An explanation may perhaps be found in the view that, in the absence of a conjugated double bond, the

FIG. 3.

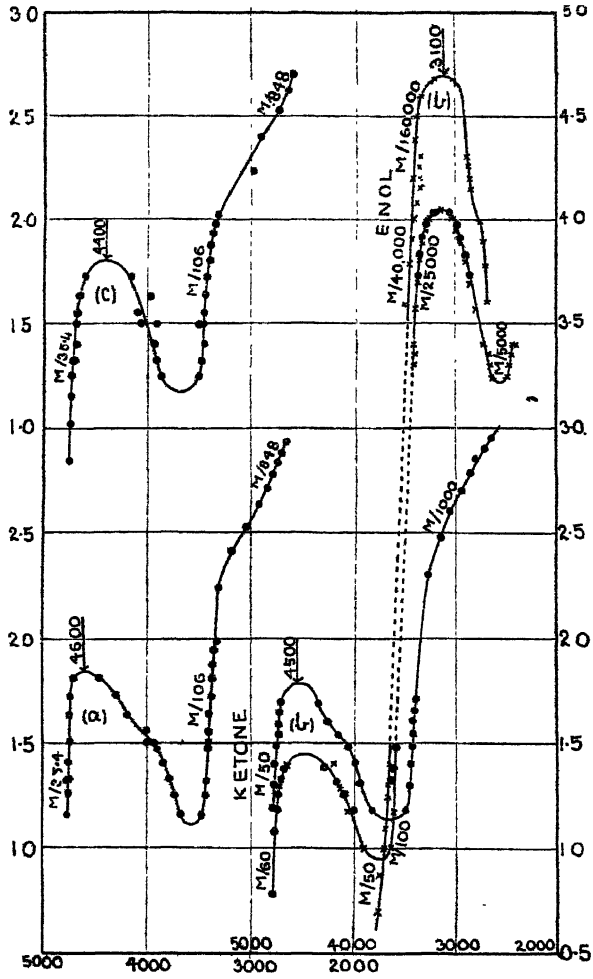
(a) *First series ;* (b) *second series.*



" ether " oxygen atom becomes interlocked with the ketonic oxygen, in much the same way as in the esters, so that the oxide may be regarded as an analogue of benzyl acetate rather than of acetophenone.

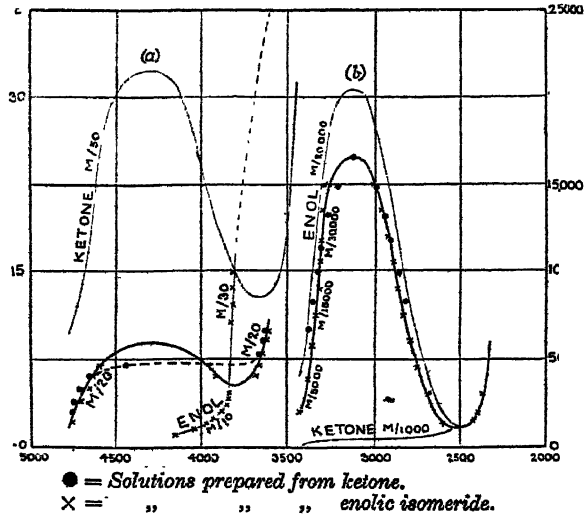
3. *Benzylmethylglyoxal and its Enolic Isomeride.*—(a) *Solid* [illegible]. The molecular extinction coefficients of the crystalline form [illegible] α-diketone in alcoholic solution are set out in Fig. 3. [illegible]

isomeric β-diketone (benzoylacetone), this compound gives only a single *maximum*, $\log \varepsilon = 4{\cdot}3$ at 3100 Å.U., corresponding closely with that of the stable form of benzoylcamphor, whilst a very strong

FIG. 4.

Molecular extinction coefficients of benzylmethylglyoxal. (a) *In cyclohexane (first series);* (b) *in cyclohexane (second series);* (c) *in chloroform.*

= *Solutions prepared from ketone.*
enolic isomeride.



minimum, $\log \varepsilon = 3{\cdot}2$ at 2480 Å.U., appears at the wave-length of the absorption band of the labile form of the latter compound. A duplicate determination gave a similar maximum, $\log \varepsilon = 4{\cdot}3$ at

3130 Å.U., but a slightly deeper minimum, extending to $\log \varepsilon = 3$. Since the solid and its freshly prepared solutions were quite colourless, it is clear that the enolic form does not give an absorption band in the visible spectrum; but this was also shown by direct observations at concentrations of $M/10$ and $M/30$, which are plotted at the foot of Fig. 5 (*a*).

A solution in *cyclo*hexane [Fig. 4 (*b*)] showed an even stronger maximum, $\log \varepsilon = 4{\cdot}7$ at 3100 Å.U., but the curve was not followed as far as the minimum, which occurs at 2500 Å.U. in the equilibrium mixture (see below). On the other hand, the absence of an absorption band in the visible region was again established by direct

FIG. 5.

Equilibrium of ketonic and enolic forms of benzylmethylglyoxal in alcohol.

× = „ „ „ *enolic isomeride.*

observations, since an $M/50$-solution showed an extinction coefficient which was already less than 5 ($\log \varepsilon = 0{\cdot}7$) at 3750 Å.U., and the absorptive power of the solution was then still diminishing according to an almost linear law as the wave-length was increased.

It is of interest to compare the bands at about 3100 Å.U. of the enolic forms of the α- and β-diketone with the bands of benzylideneacetone at 2850, and of benzylidenecamphor at 2900 Å.U. It appears certain that we are dealing throughout with the same band, but that it is displaced to a slightly longer wave-length by the introduction of the hydroxyl radical, in just the same way as the ketonic band of camphor is displaced towards the visible by the introduction of a halogen in the α- or α′-position (I.,

Owen, J., 1926, 606; compare also Grossmann, Z. *physikal. Chem.*, 1914, **109**, 329, 337). This band, although it is given by two isomeric enols, is in no sense a characteristic "enolic" band, since it is equally well developed in benzylideneacetone and benzylidenecamphor, although the hydroxyl group of the enol is absent in these two compounds; it appears, indeed, to be merely the ketonic band reinforced by conjugation of the carbonyl double bond with an olefinic double bond, exactly as in methylenecamphor (Lowry and French, J., 1924, **125**, 1921).

(b) *Liquid form.* The liquid form of the diketone reverts very easily to the crystalline form, since the yellow liquid solidifies almost immediately in the presence of a trace of a nitrogenous base. We were therefore less confident of securing an independent record of the ketonic band, especially in view of the very remarkable absorptive power of the isomeric enol. From analogy with camphorquinone, we anticipated that this band would be found in the blue region of the spectrum at about 4700 Å.U., and at a relatively high concentration, say, $\log \varepsilon = 1{\cdot}8$. We therefore made our first measurements with an $M/35{\cdot}4$-alcoholic solution, and observed the expected maximum, $\log \varepsilon = 1{\cdot}5$ at 4300 Å.U. [Fig. 3 (*a*)]. On diluting the solution, however, we found that a second maximum had already been developed in the ultra-violet at 3120 Å.U., although its intensity, $\log \varepsilon = 2{\cdot}97$, was 20 times weaker than in the case of the pure enol. We therefore repeated the experiment, taking much greater care in order to complete our observations before isomeric change had begun. The results of the second experiment, in which the exposures were completed in 50 minutes from the time when the solution was prepared, are shown in Fig. 3 (*b*). The curve no longer shows a maximum in the ultra-violet, but only a "step-out," $\log \varepsilon = 2{\cdot}6$ to $2{\cdot}8$ at 3300 to 2700 Å.U. This step-out is probably a genuine characteristic of the pure α-diketone, since it is very similar to one that had already been recorded in the case of camphorquinone (Lowry and French, J., 1924, **125**, 1921), where enolisation would appear to be impossible (Bredt, *J. pr. Chem.*, 1918, **97**, 1; *Annalen*, 1924, **437**, 1), since it would involve bending all the four bonds of the carbon atom (4) in the direction of the carbon atom (10) of the camphor nucleus. The step-out can also be compared with the one now recorded in the isomeric acetylphenylethylene oxide (VI), and may perhaps be attributed to the skeleton $C_6H_5{\cdot}C{-}C{-}CO{-}CH_3$ which is common to both isomerides.

$$\begin{array}{l} C_6H_5{\cdot}C{-}C{-}CO{-}CH_3 \\ \qquad\quad \backslash O / \end{array}$$

Confirmation of these results was obtained by making use of solutions in *cyclo*hexane, for which molecular extinctions are plotted in Fig. 4 (*a*). The curves again show a maximum ($\log \varepsilon = 1{\cdot}85$ at

4600 Å.U.) in the visible spectrum, a minimum ($\log \varepsilon = 1{\cdot}2$ at 3600 Å.U.), and a step-out at wave-lengths on either side of 3000 Å.U. A duplicate series of observations, which are plotted in Fig. 4 (*b*), gave a precisely similar curve, although the numerical values are not quite the same in the two series. The two curves agree, however, in suggesting that the band in the visible spectrum is unsymmetrical, since each curve rises almost vertically on the side of longer wave-lengths, but spreads out on the side of shorter wave-lengths, as if there were a second characteristic frequency at about 4000 Å.U.

The molecular extinction coefficients of a solution of the α-diketone in chloroform, which are set out in Fig. 4 (*c*), show the same essential characteristics, *viz.*, a maximum ($\log \varepsilon = 1{\cdot}8$ at 4400 Å.U.) in the visible spectrum, followed in the ultra-violet by a minimum ($\log \varepsilon = 1{\cdot}2$ at 3700 Å.U.), and a step-out at wave-lengths on either side of 3000 Å.U., but without any indication of a maximum at 3100 Å.U.

The principal interest of these observations is the complete separation, which has again been realised, of the characteristic absorption bands of the enolic and ketonic isomerides. Thus, on the one hand, the colourless enol is completely transparent in the region covered by the visible absorption band of the α-diketone; on the other hand, it shows no sign of the band of shorter wave-length, which is given by the labile form of benzoylcamphor, and which appears again in the absorption spectrum of benzoylacetone. Conversely, the liquid diketone, which owes its yellow colour to the presence of a characteristic quinonoid band in the blue region of the spectrum, has been dissolved in three different solvents without developing a second maximum in the ultra-violet. Each isomeride therefore retains its individuality in solution and gives rise to an absorption band of characteristic wave-length, in close agreement with the wave-length predicted from the study of compounds of analogous structure.

4. *Equilibrium Mixtures.*—On account of the remarkable absorptive power of the enolic isomeride, special care had to be used in preparing solutions of benzylmethylglyoxal, in order to avoid the development of an ultra-violet maximum, resulting from incipient enolisation of the α-diketone. Nevertheless, the pure compound is much more stable than the majority of substances in which prototropic change is liable to take place, since the yellow liquid can be kept in hard-glass tubes for many weeks without showing any signs of solidification,* although this can be induced immediately by the addition of a basic catalyst. The stability of the α-dike[illegible]

* Measurements of refractive index show that a slow transform[illegible] place even in hard-glass tubes.

and its enolic isomeride is indeed much greater than that of the two forms of benzoylcamphor, although these have been selected repeatedly for experiments on reversible isomeric change on account of the readiness with which the two isomerides can be prepared and kept. It was, however, only when we tried to prepare equilibrium mixtures of identical properties from the enolic and ketonic forms of benzylmethylglyoxal that we discovered with what difficulty the transformation is brought about in solution.

In the first instance, solutions of the two isomerides were allowed to stand for several days, since this had always proved sufficient to produce a condition of equilibrium in the case of benzoylcamphor. When dissolved in *cyclo*hexane, however, the α-diketone and its enolic isomeride had the same intensities of selective absorption even after the solution had been kept for several days. A trace of piperidine was then added, by stirring the solution of the enol with a platinum wire which had been dipped into the liquid base and drained against the side of the vessel; but even this deliberate addition of a catalyst produced no alteration in the absorptive power of the solution. Solutions of the two isomerides in *cyclo*hexane were next prepared, containing 1 mol. of piperidine for every 100 mols. of the organic compound. After 20 hours, a slight decrease was observed in the absorptive power of the ketonic form in the visible region. In the meanwhile, the enolic form had developed an absorption band in the visible spectrum at λ 4500, of intensity $\varepsilon = 12{\cdot}5$, as contrasted with $\varepsilon = 60$ for the pure ketone and $\varepsilon = 30$ for the equilibrium mixture finally obtained; but the absorptive power of this solution was unchanged after a further period of 5 days, although the ketonic and enolic solutions were still far removed from equality in this respect. These two solutions were then kept in a thermostat at 28° for 24 hours, but a glance showed that they were still of quite different depths of colour. In order to provide an amphoteric catalyst, a solution of *p*-cresol in *cyclo*hexane was now added to each solution, in quantity such that the molar concentrations of piperidine and *p*-cresol were equal in the resulting mixture. The maximum absorptive power of the ketonic solution in the visible spectrum at λ 4500 fell to $\varepsilon = 30$, but that of the enol at the same wave-length was not altered by this addition of cresol, but remained constant at λ 12·5. When diluted, the solution of the enol gave $\varepsilon = 5000$ at λ 3150, whilst the solution of the ketone gave $\varepsilon = 60$, but in neither case was a definite absorption band developed.

Equilibrium mixtures which gave identical extinction coefficients were finally obtained by adding 1 mol. % of piperidine to the dissolved ketone or enol and keeping the solutions for 20 hours in

closed flasks at 50°. The equality of visual colour of the two solutions was confirmed by measurements with a Kletz colorimeter against a solution of camphorquinone. The results were as follows:

In *cyclo*hexane:

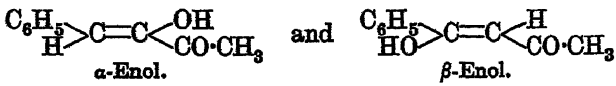
$$\frac{\text{Camphorquinone, } M/60}{\text{Ketonic solution, } M/20} = 1{\cdot}88,\ 1{\cdot}92. \quad \text{Mean} = \mathbf{1{\cdot}90}.$$

$$\frac{\text{Camphorquinone, } M/60}{\text{Enolic solution, } M/20} = 1{\cdot}81,\ 1{\cdot}92. \quad \text{Mean} = \mathbf{1{\cdot}87}.$$

In ethyl alcohol:

$$\frac{\text{Camphorquinone, } M/180}{\text{Ketonic solution, } M/20} = 0{\cdot}96,\ 0{\cdot}99,\ 0{\cdot}96,\ 1{\cdot}03. \quad \text{Mean} = \mathbf{0{\cdot}98}.$$

$$\frac{\text{Camphorquinone, } M/180}{\text{Enolic solution, } M/20} = 1{\cdot}00,\ 0{\cdot}88,\ 0{\cdot}97,\ 0{\cdot}94. \quad \text{Mean} = \mathbf{0{\cdot}95}.$$



The equilibrium mixture in *cyclo*hexane has therefore rather more than one-sixth of the intensity of colour of camphorquinone, whilst in ethyl alcohol the ratio is rather more than one-ninth; but, since this ratio depends on the width of the bands, as well as on their intensity, it cannot be used to deduce the ratio of the maximum extinction coefficients, as measured with a spectrophotometer.

Quantitative data for the molecular extinction coefficients of solutions in *cyclo*hexane are shown in Fig 4 (*b*), and those of alcoholic solutions are shown in Fig. 5, where different scales of intensity are used for the visual region of the ketonic band and for the ultra-violet region of the enolic band. In each case the circles represent values recorded for solutions of the ketone itself, and crosses are used for solutions prepared from the enolic isomeride. The two series of data can be represented by a single curve for each solvent, the largest deviation being at the ketonic band of Fig. 5 (*a*), where the solution of the enol showed a shallow maximum and minimum, whereas the solution prepared from the ketone gave only a step-out; the points on either side of the loop can, however, be plotted on a single curve.

The circumstances in which these experiments were made were not suitable for deducing the equilibrium proportions of the ketonic and enolic forms, since the conditions of equilibrium were not well defined, and the dilutions at which the ketonic and enolic bands were observed differed very widely. It is therefore not surprising that the proportion of ketone (about $\frac{1}{2}$) in *cyclo*hexane at a dilution of $M/60$ and of enol (about $\frac{1}{4}$) in the same solvent at a dilution of $M/25{,}000$ do not add up to unity. In the case of the alcoholic solutions, the proportions of ketone and enol deduced from the extinction coefficients at the wave-lengths of the two maxima are roughly $\frac{1}{2}$ and $\frac{1}{3}$ at dilutions of $M/20$ and $M/30{,}000$, respectively;

in this solvent, therefore, there appear to be 3 or 4 parts of enol to one of ketone, but this ratio also is rendered uncertain by the widely different concentrations at which the proportions of ketone and enol were determined, and by deviations from Beer's law, which are shown by the varying width of the absorption bands as observed in solutions of different concentrations. Attention should also be directed to the fact that at the wave-length λ 3800, at which the enol and the ketone have the same extinction coefficient, $\varepsilon = 15$, in alcoholic solutions, the equilibrium mixture has an absorption coefficient which is only about half as great. This anomaly throws doubt on the validity of the additive law as applied to mixtures of the α-diketone and its enolic isomeride, and suggests that they may perhaps unite with one another (like quinol and quinone) to form an unstable complex in solution.

Although the proportions of the isomerides cannot be deduced with certainty from the absorption curves for the equilibrium mixtures, these curves provide very important evidence as to the qualitative composition of these mixtures. Thus, if the two absorption bands of benzoylacetone, or of the two forms of benzoylcamphor, were characteristic of a pair of stereoisomeric enols, it would be difficult to exclude the possibility of a similar stereoisomerism in the enolic form of the α-diketone, as may be seen by comparing the formulæ

α-Enol. and β-Enol.

Actually, however, the absorption curves for equilibrium mixtures of the two forms of benzylmethylglyoxal give no indication of the maximum at λ 2450, which is characteristic of the labile form of benzoylcamphor, and which is also seen in the absorption spectrum of benzoylacetone. On the contrary, the curves for solutions in alcohol and in *cyclo*hexane actually pass through a *minimum* in this region of the spectrum. The band at λ 2450 must therefore be associated with a structure which is not only different from those of the two known forms of benzylmethylglyoxal, but is not produced from either of them by isomeric change in presence of a catalyst. Such a form cannot be a mere stereoisomeride, although it might conceivably be a co-ordinated enol, containing a 6-atom ring which could not be produced from an α-diketone.

Summary.

Benzylmethylglyoxal, $C_6H_5 \cdot CH_2 \cdot CO \cdot CO \cdot CH_3$, shows an absorption band in the visible spectrum, with a maximum $\log \varepsilon = 1{\cdot}5$ at 4300 in alcohol, or $\log \varepsilon = 1{\cdot}85$ at 4600 in *cyclo*hexane, but only a " step-

out" in the ultra-violet at about 3000 Å.U. The enolic isomeride, $C_6H_5{\cdot}CH{:}C(OH){\cdot}CO{\cdot}CH_3$, on the other hand, is colourless, but has a strong absorption band in the ultra-violet with a maximum $\log \varepsilon = 4{\cdot}3$ at 3100 in alcohol, or 4·7 at 3100 in *cyclo*hexane. Both bands are given by solutions in which the two isomerides are in equilibrium.

CCCCXXI.—*Studies of Valency. Part XII. Isomeric Derivatives of Diethyl Telluride.*

By FRANK LATHE GILBERT and THOMAS MARTIN LOWRY.

VERNON'S last paper on "Organic Derivatives of Tellurium" concludes as follows: "There is still much work to be done on this subject, and it would be of interest to find out whether other aliphatic derivatives, such as diethyltelluronium di-iodide, also exist in two isomeric forms. The reason that no further investigation is being undertaken is entirely due to the intolerable nature of tellurium and its derivatives" (J., 1921, **119**, 696). The present paper describes the completion of the investigation which Vernon contemplated, but was not able to undertake. This investigation has led to the discovery that diethyl telluride, like the dimethyl compound, yields two series of isomeric salts, and that these are derived from two isomeric bases, which are related to one another in precisely the same way as the α- and β-bases of the dimethyl series. This result was by no means a foregone conclusion, since the cyclic base prepared by Morgan and Burgess (this vol., p. 321) does not undergo isomeric change when evaporated to dryness (Gilbert and Lowry, this vol., p. 2658), although the di-iodide exists in two enantiotropic forms; and Mr. W. H. Mills has informed us that the diphenyl compound also shows no analogous transformation when treated in the same way as the dimethyl base. The isomeric derivatives now described therefore provide the first experimental justification for the view that the isomerism discovered by Vernon is not restricted to the methyl compounds, and may be a general property of the dialkyltelluronium bases and salts.

The salts in which this isomerism has been detected have been known for nearly a century. They were prepared by Wöhler (*Annalen*, 1840, **35**, 111; 1852, **84**, 73; 1855, **93**, 233) and Mallet (*ibid.*, 1851, **79**, 223) by oxidising diethyl telluride to dinitrate, $TeEt_2(NO_3)_2$, by the action of nitric acid. From

the chloride, bromide and iodide, the sulphate and oxalate, the oxide and the oxyhalides were obtained, but without any indication of isomerism or of isomeric change. Vernon prepared the α-di-iodide, $TeEt_2I_2$, by the action of ethyl iodide on metallic tellurium and analysed the product; it melted at 57°, whereas Wöhler gives the m. p. as 50°. He also prepared the base by the action of silver oxide on the iodide, and added that "If this base does not decompose when its solution is evaporated to dryness, but gives diethyltelluronium oxide, the existence of two haloid series would be highly probable." Our first attempt to verify this prediction gave rise to *diethyltellurone*, $TeEt_2O_2$, by spontaneous oxidation of the base, whereas the α- and β-dimethyl bases and Morgan's cyclic base are only oxidised to the tellurone by boiling with hydrogen peroxide; but by evaporating a solution of the α-base to dryness in an atmosphere of nitrogen, a substance was obtained which gave in aqueous solution quite different reactions towards silver nitrate and hydriodic acid and evidently contained the isomeric β-base. From this substance a characteristic series of β-salts was prepared.

The two series of isomeric salts correspond very closely with those of the dimethyl series. Thus the α-di-iodide differs from the β-compound in that it is freely soluble in chloroform, and can be converted into a tetra-iodide. The remarkable contrast which Vernon observed between the action of alkalis on the α- and β-salts was also repeated in the diethyl series. Thus, the α-di-iodide gave rise to an *oxyiodide*, $I[TeEt_2{\cdot}O{\cdot}TeEt_2]I$, although this was produced under a wider range of conditions than in the methyl series, since the same product was obtained when we tried to prepare the ethyl analogue of Vernon's beautifully crystalline α-dimethyltelluronium dioxyiodide. The β-di-iodide, on the other hand, was converted by the action of alkali into a salt having the characteristics and the approximate composition of a *triethyltelluronium iodide*, $TeEt_3I$.

A remarkable contrast is found in the fact that the α- and β-chlorides and bromides of the diethyl series are obtained as oils, whereas those of the dimethyl series are crystalline solids of fairly high melting point. A close analogy (comparable with that which has already been pointed out in connexion with the conductivities; this vol., p. 314) is found, however, in the trialkylstibine series, where the trimethylstibine dihalides are all solid, as is also the triethylstibine di-iodide, whereas the triethylstibine dichloride and dibromide are liquids.

Apart from this contrast in melting points, the physical properties of the diethyl compounds are in general such as we should have expected in the light of our observations on the dimethyl series. For instance, the absorption spectra of the iodides all show the

twin maxima of the "iodoform band," and the bromides exhibit only a step-out. Again, measurements of molecular conductivity show that, when dissolved in water, the dihalides lose one atom of halogen by hydrolysis to the free acid, giving rise to hydroxy-halides, to which the general formula $[TeEt_2 \cdot OH]X$ is assigned. The only compound of the group which has been isolated is, however, the α-oxyiodide, $I[TeEt_2 \cdot O \cdot TeEt_2]I$. The hydroxy-halides are ionised more or less completely in aqueous solution, but are not hydrolysed even in dilute solutions from which the excess of acid has been removed. As in the methyl series, they are acid rather than alkaline in their reaction.

An interesting comparison can be made between the properties of the α- and the β-base. As in the dimethyl series, the β-base has a higher conductivity than the isomeric α-base, and it is also shown by potentiometric titrations to be stronger than the α-base during the first half of the process of neutralisation. At this stage, however, the curves cross, so that the β-base is seen to be weaker than the α-base after half-neutralisation. The crossing of the curves is due to the fact that, whilst the α-base gives a neutralisation curve of the normal type, the curve for the β-base is inflected, exactly as in the case of the α-dimethyl base (this vol., p. 1997), although not to such a marked extent. The reappearance of this inflected curve in the case of the β-base, and the absence of any inflexion in the curve for the α-base, provide the most striking evidence of the persistent analogy between the methyl and ethyl series of compounds.

EXPERIMENTAL.

α-Diethyltelluronium Di-iodide.—Precipitated tellurium (crushed crystalline tellurium is less effective) is heated in Carius tubes for 10 days at 100° with ethyl iodide (2 mols.), the tubes being shaken every 12 hours. Very little pressure is developed, even at 100°, and there is no pressure when the tubes are opened. Since the compound has been found to decompose slightly during fusion, it would probably be better to heat at 40—50° during a period of perhaps 20 days, so that the compound is not prepared in the fused state. The di-iodide was extracted with hot chloroform (instead of with alcohol, as recommended by Vernon), filtered through a hot funnel to remove unchanged tellurium, and separated by rapid evaporation. It was obtained from alcohol in large brownish-red crystals, m. p. 57°; yield, about 20%. The final product was identical in all respects with a specimen left by Vernon.

The *α-tetraiodide*, $TeEt_2I_4$, was obtained as a black residue by mixing a violet solution of iodine and a yellow solution of the α-di-iodide in chloroform, and refluxing the mixture for one minute,

the colour almost wholly disappearing; but some decomposition occurred in this process, giving rise to free iodine and tellurium. The α-tetra-iodide was also formed when hydriodic acid was added to a solution of the α-base, which had been partly oxidised by boiling with hydrogen peroxide for a few minutes, and then filtered from the resulting diethyltellurone. It melts at 98°, and loses iodine in the air, regenerating the α-di-iodide. (After reduction with sulphur dioxide and addition of nitric acid, Volhard's method gave I, 71. $TeEt_2I_4$ requires I, 73·2%).

The β-di-iodide does not combine with iodine under the conditions described above.

Preparation and Properties of the α-Base.—The α-base, which was described by Mallet as a colourless, crystalline mass, and by Wöhler as a white, amorphous mass, was prepared by grinding the solid α-di-iodide with fresh moist silver oxide, in exactly the same way as the corresponding dimethyl base. When hydriodic acid was added to the aqueous solution, the α-di-iodide was regenerated as a bright yellow precipitate, settling to a red solid. Silver nitrate gave a white precipitate, turning brown and then black. On evaporation to dryness at 100° under 15 mm. pressure, a colourless oily residue was left, which changed to a white non-crystalline solid when it was allowed to cool and to come in contact with cold water. This product, which was sparingly soluble in water and insoluble in organic solvents, decolorised permanganate and liberated violet fumes of iodine when warmed with concentrated hydriodic acid. Analysis showed that the α-base had been oxidised to *diethyltellurone*, $TeEt_2O_2$ (0·0254 g. gave 0·0147 g. Te when oxidised with aqua regia and reduced with sulphur dioxide and hydrazine hydrochloride: Te, 58·0. $TeEt_2O_2$ requires Te, 58·6%).

Preparation and Properties of the β-Base.—The β-base was obtained by evaporating a solution of the α-base to dryness at 100° under 15 mm. pressure in a stream of nitrogen. In order to dissolve it, a sealed tube of air-free water was broken inside the flask, which was then filled with nitrogen under atmospheric pressure. The β-base was then quite stable and resistant to oxidation, but was mixed with some unchanged α-base and some diethyltellurone. To purify it, hydriodic acid was added to the solution, and the mixed di-iodides were washed with a few drops of cold chloroform (in which the α-di-iodide is freely soluble); the pure β-di-iodide was then reconverted into the β-base by the action of silver oxide.

The β-base gives a faint white precipitate with silver nitrate, which turns black on boiling, but not in the cold. With hydriodic acid it gives a dark red precipitate of the β-di-iodide which settles to a purple solid; the presence of any α-base as impurity can be

detected by the formation of a fine yellow precipitate which remains at the top of the beaker.

Preparation and Properties of the β-*Di-iodide.*—The β-*di-iodide* can be prepared in a crude form by the action of hydriodic acid on the crude β-base, and freed from the α-isomeride by washing with chloroform, in which it is almost insoluble. It can also be obtained (free from the α-isomeride) by the action of hydriodic acid on diethyltellurone. It separates from methyl alcohol in dark purple crystals, m. p. 42° (Found: I, 57·2. $TeEt_2I_2$ requires I, 57·9%). It is also readily soluble in acetone, but gives a lachrymatory vapour (possibly iodoacetone) when the solution is evaporated.

α- *and* β-*Dibromides.*—The α-dibromide was obtained by Wöhler as a pale yellow oil of high boiling point. We obtained it in a similar form (Found: Br, 46·2. Calc. for $TeEt_2Br_2$: Br, 46·4%), but found that it solidified when cooled with a freezing mixture of ice and salt. When freed from the mother-liquor and dried in a vacuum desiccator, the solid does not melt till + 24°, but it does not then resolidify on cooling. The β-*dibromide* was obtained as a yellow oil of deeper colour, and solidified to a glass at −12° (Found: Br, 46·0. $TeEt_2Br_2$ requires Br, 46·4%).

α- *and* β-*Dichlorides.*—The α-dichloride was prepared by Mallet, who distilled it without decomposition at a temperature too high to be measured. We obtained it as a colourless oil (Found: Cl, 27·0. Calc.: Cl, 27·6%) which froze to a glass in a freezing mixture at −12°, and melted again at −5°. The β-*dichloride* was also obtained as a colourless oil (Found: Cl, 27·8. $TeEt_2Cl_2$ requires Cl, 27·6%) which solidified in a freezing mixture and melted again at −10°.

Action of alkalis. (a) In order to prepare a "dioxyiodide," the α-di-iodide was ground up with a little concentrated ammonia, dissolved in the minimum quantity of water, and left to crystallise in a vacuum desiccator. Colourless crystals separated, which melted at 107° and turned red on exposure to air; but these were shown by analysis to be an α-*monoxyiodide*, to which the formula $I[TeEt_2{\cdot}O{\cdot}TeEt_2]I$ may be assigned (I, 39·0; calc., 39·5%). When the crystals were boiled with water and cooled, in order to convert the supposed "dioxyiodide" into a "monoxyiodide," the same product was obtained (I, 39·9; calc., 39·5%), but in a less pure form, since it melted at 104—106°. This was a sticky, orange-yellow precipitate, which resembled the yellow "monoxyiodide" of the methyl series; but, unlike the methyl compound, it did not lose its colour after long standing in contact with water; nor did it lose its colour when recrystallised from hot water.

(b) The product obtained by boiling the β-di-iodide with

equivalent of sodium carbonate in concentrated solution, and then cooling, was a white precipitate, which was washed with a drop of ice-cold water. It had the properties of a *triethyltelluronium iodide*, since it did not change colour when exposed to acid fumes, and blackened without melting above 180°. It was appreciably soluble in water, but insoluble in organic solvents; it was therefore not easy to free it completely from sodium carbonate, the low percentage of iodine found on analysis thus being accounted for (Found: I, 35·9. $TeEt_3I$ requires I, 37·3%).

Action of mercury diphenyl. Vernon directs attention to the "almost unique" action of mercury diphenyl on α-dimethyltelluronium di-iodide and states that the interaction with the α-diethyl compound "does not take place in this curious manner." On mixing equimolecular solutions in chloroform of mercury diphenyl and of the α-di-iodide, $TeEt_2I_2$, the brown colour of the solutions became yellow, and after about 5 seconds a yellow precipitate was suddenly formed, very much as in the case of the dimethyl compound. This precipitate was a heavy, yellowish-green oil; when cooled to −8°, it solidified to a pale yellow, crystalline mass, and then remained solid up to 94°. (The α-methyl compound melts at 125°.) The addition compound is soluble in acetone, but does not crystallise well from this solvent. When boiled with chloroform or alcohol, it liberates a smell resembling that of carbylamine. Analysis showed that it contains two molecules of the di-iodide to one of mercury diphenyl [Found: Hg + Te, 36·3. $(TeEt_2I_2)_2,HgPh_2$ requires Hg + Te, 35·0%]. Mercury di-*p*-tolyl does not appear to interact with α-dimethyl- or α-diethyl-telluronium di-iodide.

Absorption Spectra.

The absorption spectra of the dimethyl series had been determined in specially dried alcohol in order to avoid hydrolysis (this vol., p. 308), but since Batley (*Trans. Faraday Soc.*, 1928, **24**, 438) has described a reaction between alcohol and iodine, it was thought preferable to measure the absorption spectra in a more inert solvent. They were therefore observed in *cyclo*hexane, which had been shaken with oleum and with sodium carbonate, dried, and fractionated.

The α-dihalides are readily soluble in *cyclo*hexane. The β-dihalides are only very sparingly soluble, but since only very dilute solutions were required, the concentrations of the saturated solutions were found to be sufficient. The extinction coefficients of the α- and β-di-iodides and of the α- and β-dibromides of the diethyl series were measured; but not those of the dichlorides or of the hydroxy-salts, which give only general absorption. For the

purpose of comparison, the absorption spectra of α- and β-dimethyltelluronium di-iodides were also measured in *cyclo*hexane.

The most important values of λ and of log ε are set out in Table I, and the corresponding absorption curves are plotted in Fig. 1. The general results are very similar to those already recorded for solutions of the dimethyl salts in alcohol, but the absolute values of the extinction coefficients in *cyclo*hexane are higher than in ethyl alcohol; the wave-length of the head of the band is also shorter in every case.

FIG. 1.

Molecular extinction coefficients in cyclo*hexane.*

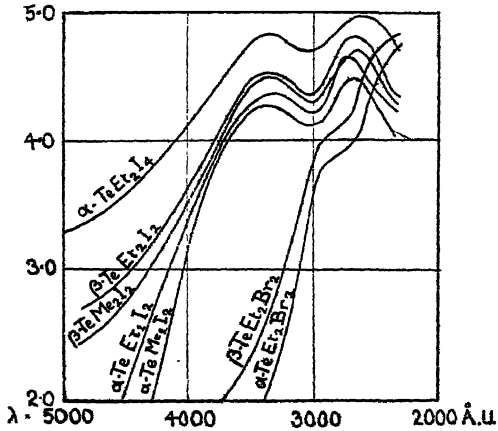

TABLE I.

Extinction Coefficients of Diethyltelluronium Dihalides.

α-$TeMe_2I_2$	λ = 3400 at log ε = 4·27;	λ = 2680 at log ε = 4·47
β-$TeMe_2I_2$	λ = 3360 at log ε = 4·49;	λ = 2640 at log ε = 4·70
α-$TeEt_2I_2$	λ = 3350 at log ε = 4·36;	λ = 2700 at log ε = 4·65
β-$TeEt_2I_2$	λ = 3350 at log ε = 4·51;	λ = 2670 at log ε = 4·80
α-$TeEt_2I_4$	λ = 3350 at log ε = 4·82;	λ = 2630 at log ε = 4·95
α-$TeEt_2Br_2$	Step-out from λ 2900 to 2660 at log ε = 3·8 to 4·0	
β-$TeEt_2Br_2$	Step-out from λ 2900 to 2690 at log ε = 4·0 to 4·2	

Molecular Conductivities.

These were determined at 25° in cells of which the constants were 0·2240 and 0·1250 cm.$^{-1}$. Since the dihalides were difficult to dissolve and it was inadvisable to boil them with water, they were dissolved in the minimum quantity of cold ethyl alcohol and the solutions were diluted with cold conductivity water. The amount of alcohol in the most concentrated solution is shown in parentheses in Table II and was never more than 4%; and this, of course, is halved at each dilution. A correction, of 2½ times the percentage of alcohol, was applied to the final conductivity values.

validity of this correction has already been demonstrated (this vol., p. 313).

The solutions of the bases were standardised by titration against $N/10$-hydrochloric acid with bromophenol-blue as indicator. Solutions of the hydroxyhalides were prepared by mixing equimolecular solutions of dihalide and base. The β-dichloride was not investigated, since after purification and analysis there was not sufficient material available.

The molecular conductivities at 25° are summarised in Table II. The behaviour of the salts is similar to that of the dimethyl salts, but there is some contrast in the behaviour of the bases. For instance, whilst the α-base has the same low conductivity as the corresponding methyl base, the β-base has a conductivity ranging from 8 to 16 units as compared with 34 to 37 for the β-base of the methyl series. The somewhat higher values recorded for the β-base prepared from α-base are doubtless due to traces of impurities in the solution. A solution of the crystalline oxyiodide, $I[TeEt_2{\cdot}O{\cdot}TeEt_2]I$, made up without the use of alcohol, gave molecular conductivities which were slightly less than twice the values recorded for the hydroxyiodide, exactly as was observed in the methyl series (this vol., p. 2006).

Potentiometric Titrations.

These were carried out with a glass electrode, *N*-hydrochloric acid being used for the titration. The glass electrode had a very thin bulb, and gave about 56 millivolts per p_H. The potentials were checked by taking readings of an acid and an alkaline solution of

FIG. 2.

Potentiometric titrations.

known p_H every time a titration was made. Two curves for the α-diethyltelluronium base and two for the β-base (prepared in each case from the β-salt) are shown in Fig. 2, and some of the principal data are summarised in Table III.

The curves for the α-base are quite normal; those for the β-base show an intermediate inflexion at 50% neutralisation, although of less pronounced character than in the case of the methyl base. The inflexion at 100% neutralisation corresponds in each case with

formation of the hydroxyhalide, $[TeEt_2OH]Cl$, but there is no sign of the second hydroxyl being neutralised at 200% neutralisation, nor is there any indication of basic compounds apart from the inflexion in the curves for the β-base. The curve for the $N/16{\cdot}5$-solution of the α-base is on the acid side of that for the $N/11{\cdot}4$-solution, as might be expected; this is also true of the $N/26$- and $N/13{\cdot}4$-solutions of the β-base. An anomaly is found in the fact that the foot of the curve for the α-base is on the alkaline side of that for the β-base, which has a higher molecular conductivity; but we do not attach any importance to this anomaly, since it disappears after 2 or 3 drops of acid have been added.

The data cited in Table III show that the dissociation constant K_b of the α-base is given by $-\log K_b = 7{\cdot}5$. The strength of the β-base cannot be deduced from the p_H at half-neutralisation, since the curve is inflected at this point, but it can be deduced from the relation $-\log K_b = \log\{(1-x)/x\} + p_{K_w} - p_H$, where x is the fraction of base neutralised. The p_H at 25% neutralisation then gives $-\log K_b = 6{\cdot}7$. The β-base is therefore stronger than the α-base, which is in accordance with the conductivity measurements. The p_H at 75% neutralisation shows that the dissociation constant of the basic salt formed at 50% neutralisation of the β-base is $-\log K_b = 7{\cdot}62$.

The relationship between the dimethyl- and the diethyl-telluronium bases is as follows: the two α-bases are of exactly the same strength, $-\log K_b = 7{\cdot}5$; the true β-methyl base, $-\log K_b = 6{\cdot}2$, is stronger than the β-ethyl base, $-\log K_b = 6{\cdot}7$; but the basic salt $2TeEt_2O,HCl$, $-\log K_b = 7{\cdot}62$, is a stronger base than the basic salt $2TeMe_2O,HCl$, $-\log K_b = 8{\cdot}7$.

Summary.

1. α-Diethyltelluronium di-iodide yields an α-base, which is converted into an isomeric β-base when the aqueous solution is evaporated to dryness in a vacuum.

2. From the β-base a series of β-salts can be prepared. The two series of salts differ in their behaviour towards alkali, since the

α-iodide gives a colourless monoxyiodide, whereas the β-iodide gives a triethyltelluronium salt; and a tetra-iodide could only be prepared from the α-base.

3. The β-base is stronger than the α-base, and gives an inflected potentiometric curve, as in the methyl series.

We are indebted to the Department of Scientific and Industrial Research for a maintenance grant to one of us (F. L. G.) during the period in which this research was made.

UNIVERSITY CHEMICAL LABORATORY,
CAMBRIDGE. [*Received, October 31st*, 1928.]

CCCCXXII.—*Stereoisomerism of Disulphoxides and Related Substances. Part III. Some Pairs of Aromatic Disulphoxides.*

By ERNEST VERE BELL and GEORGE MACDONALD BENNETT.

AN examination of the products of oxidation of several aromatic disulphides of the general formulæ $Ar{\cdot}S{\cdot}C_2H_4{\cdot}SAr$ and $C_6H_4(SR)_2$ shows that in each case a pair of diastereoisomeric disulphoxides is produced.

s-Dibenzylthiolethane was oxidised by Fromm, Benzinger, and Schäfer (*Annalen*, 1912, **394**, 325) to a disulphoxide of m. p. 198°. A re-investigation of this substance shows it to be a mixture of two *isomerides* melting at 209° and 191° respectively. We have also prepared two new disulphides of the same type, namely, s-*diphenylthiolethane*, m. p. 69°, and s-*di*-p-*tolylthiolethane*, m. p. 81°, and each was oxidised by hydrogen peroxide to a mixture in about equal proportion of two isomerides: the *ethylene diphenyl disulphoxides*, α- of m. p. 166° and β- m. p. 123°; the *ethylene di*-p-*tolyl disulphoxides*, α- m. p. 174° and β- m. p. 127°.

The oxidation of *m*-dimethylthiolbenzene yields an *α-disulphoxide*, m. p. 147°, and a *β-disulphoxide*, m. p. 102°, each distinct in properties from the substance described by Zincke and Krüger (*Ber.*, 1912, **45**, 3468), which was doubtless a mixture of the two. The α-disulphoxide, m. p. 133°, of *m*-dibenzylthiolbenzene is, however, evidently identical with the disulphoxide obtained by the same authors, but we have isolated in addition a *β-disulphoxide*, m. p. 123°, from the mother-liquors of crystallisation of the former substance.

In the same way, the disulphoxide, m. p. 188°, (now α-) of *p*-dimethylthiolbenzene (Zincke and Frohneberg, *Ber.*, 1909, **42**, 2721) was found to be accompanied by a more soluble *β-disulphoxide*,

m. p. 136°, which, like its isomeride, yields a crystalline *mercurichloride*.

The members of each of these pairs of isomerides are sharply differentiated by their melting points, crystal forms and solubilities. In each case they were shown to be readily reduced to the parent disulphide, the alternative structure of a monosulphone being thereby excluded. Mixtures of the two related substances do not show a sharply depressed melting point, but in all cases melt over a range of temperature.

Negative results were obtained when attempts were made to isolate a crystalline bromide or hydrochloride of any of these disulphoxides (compare Part II, this vol., p. 86).

EXPERIMENTAL.

Condensation of Thiophenol and p-*Thiocresol with Ethylene Dibromide.*—Thiophenol (13·5 g.) in ethyl alcohol (100 c.c.) was heated on the steam-bath for 1 hour with potassium hydroxide (6·9 g. in a little water) and ethylene dibromide (11·3 g.). When the solvent had been removed in a current of steam, the residual oil solidified on cooling (yield, 14·6 g.). s-*Diphenylthiolethane*, thus obtained, crystallised from ethyl alcohol in colourless, monoclinic plates, m. p. 69° (Found: C, 68·0; H, 5·8. $C_{14}H_{14}S_2$ requires C, 68·3; H, 5·7%).

A similar operation using *p*-thiocresol (31·0 g.) gave s-*di*-p-*tolylthiolethane* (30 g.), which crystallised from ethyl alcohol in colourless, monoclinic plates, m. p. 81° (Found: S, 23·4. $C_{16}H_{18}S_2$ requires S, 23·35%).

Oxidation of the Disulphides with Hydrogen Peroxide.—In all cases to be described in this paper, the disulphide was oxidised by adding to its solution in glacial acetic acid the calculated amount of 25% hydrogen peroxide. After 24 hours the acetic acid was removed from the mixture in a current of steam, followed by evaporation to dryness on a steam-bath, the crude oxidation product being thus obtained in quantitative yield.

Isomeric Dioxides from Diphenylthiolethane.—The crude oxidation product, insoluble in water, but soluble in most organic solvents, was separated, by fractional crystallisation from toluene, into two isomerides which appear to be formed in approximately equal proportion.

The *α-disulphoxide* (yield of pure substance from 5 g. of the disulphoxide, 1·2 g.) formed colourless, monoclinic plates or tables, m. p. 166° (decomp.), from ethyl alcohol (Found: C, 60·3; H, 5·0; S, 23·3. $C_{14}H_{14}O_2S_2$ requires C, 60·4; H, 5·0; S, 23·0%). The *β-disulphoxide* (yield, 0·8 g.) separated from alcohol in colourless needles with straight extinction, m. p. 123° (decomp.), and was

much more soluble in organic solvents than the preceding substance (Found: S, 22·8%).

Reduction of the Disulphoxides.—In this and each other instance the isomerides were reduced in alcoholic solution by means of zinc dust and hydrochloric acid and the product was found by its melting point and by that of a mixture with the parent disulphide to be identical with the latter.

Isomeric Dioxides of Di-p-tolylthiolethane.—The oxidation product was a mixture of two substances, present in equal proportion and separated by fractional crystallisation from toluene. The *α-disulphoxide* (yield of pure substance, 1·1 g. from 9·1 g. of disulphide) may be crystallised from benzene, toluene, xylene, ethyl, butyl or amyl alcohol, or ethyl acetate, but it is insoluble in water. It separates from ethyl alcohol in small rhomb-shaped plates with diagonal extinction and a high double refraction; m. p. 173—174° (decomp.) (Found: S, 20·8. $C_{16}H_{18}O_2S_2$ requires S, 20·9%). The *β-disulphoxide* (yield, 0·9 g.) is more soluble in all solvents than its isomeride, but is insoluble in water. It separates from its highly concentrated solution in ethyl alcohol in needles with straight extinction, m. p. 126—127° (decomp.) (Found: S, 20·7%).

Isomeric Dioxides of Dibenzylthiolethane.—The crude dioxides (10·7 g. from 10·0 g. of the disulphide) were separated by crystallisation from amyl alcohol. The *α-disulphoxide* separated in small monoclinic plates from ethyl or amyl alcohol or 50% acetic acid, and in flat prisms from xylene, m. p. 209° (Found: S, 21·0. $C_{16}H_{18}O_2S_2$ requires S, 20·9%). The *β-disulphoxide* was freed from the last traces of the α-isomeride by crystallisation from xylene. It separated from xylene or amyl alcohol in feathery needles having a straight extinction, m. p. 192° (Found: S, 21·0%). The disulphoxide described by Fromm, Benzinger, and Schäfer (*loc. cit.*) had m. p. 198°.

Isomeric Dioxides of 1 : 3-*Dimethylthiolbenzene.*—The crude product of oxidation was separated by crystallisation from benzene into two substances present in approximately equal quantities: the *α-disulphoxide*, crystallising from benzene in plates with a high double refraction and a straight extinction, m. p. 147° (Found: S, 32·0. $C_8H_{10}O_2S_2$ requires S, 31·7%), and the more soluble *β-disulphoxide*, which separated from benzene in rhomb-shaped crystals with an oblique extinction, m. p. 102° (Found: S, 31·8%). The substance described by Zincke and Krüger (*loc. cit.*) had m. p. 131°.

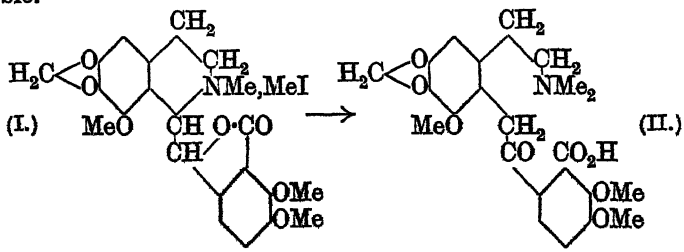
The reduction of these two disulphoxides yielded the [illegible] disulphide, which is a liquid. Its identity was confirmed in [illegible] cases by the preparation of the crystalline *mercurichloride* [illegible] 1 : 3-

dimethylthiolbenzene, m. p. 108° (Found: Hg, 45·5. $C_8H_{10}S_2Cl_2Hg$ requires Hg, 45·3%).

Isomeric Dioxides of 1 : 3-*Dibenzylthiolbenzene.*—Two substances, present in about equal proportion, were separated from the oxidation product by fractional crystallisation from toluene and mixtures of this solvent with petroleum of b. p. 100—120°.

The *α-disulphoxide* crystallised from toluene or ethyl alcohol in almost square plates with diagonal extinction, m. p. 133° (Found: S, 18·0. $C_{20}H_{18}O_2S_2$ requires S, 18·1%). The more soluble *β-disulphoxide* separated in minute, rhomb- or hexagonal-shaped crystals from toluene and in characteristic spherical aggregates from carbon tetrachloride; m. p. 123° (Found: S, 18·3%). The substance described by Zincke and Krüger had m. p. 131°.

Isomeric Dioxides from 1 : 4-*Dimethylthiolbenzene.*—The crude mixture was readily soluble in water and moderately easily soluble in other solvents. Crystallisation from toluene, ethyl alcohol, benzene, and ethyl acetate separated two isomeric dioxides. The α-disulphoxide (yield, 2·3 g. of pure substance from 10 g. of the disulphide) crystallised from water in rhomb-shaped plates with an oblique extinction, m. p. 183° (Found: S, 31·7. Calc. for $C_8H_{10}O_2S_2$: S, 31·7%). Zincke and Frohneberg (*loc. cit.*) gave the m. p. as 188°. The mercurichloride was obtained in silvery plates, m. p. 216° (decomp.), sparingly soluble in water (Found: Hg, 42·25. Calc. for $C_8H_{10}O_2Cl_2S_2Hg$: Hg, 42·3%). Zincke and Frohneberg give the m. p. as 220°. The *β-disulphoxide* (yield, 2·2 g.) is more soluble than its isomeride in all solvents. It crystallises in branching needles with an oblique extinction, m. p. 136° (Found: S, 31·7%), and forms a mercurichloride similar to that of the α-isomeride, but much more readily soluble in water and having m. p. 188° (decomp.).

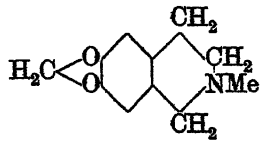


Note on the Determination of Sulphur.—The method of Pregl ("Quantitative Organic Microanalysis," English ed., 1924, p. 102) has proved very useful on the macro-scale. Ordinary combustion tube is constricted at a point which divides it into a length of 50 cm. (for the boat and platinum catalysts) and 35 cm. (for glass beads). The acid produced is titrated with *N*/10-alkali and phenolphthalein. The time required for an analysis is less than for an ordinary combustion.

THE UNIVERSITY, SHEFFIELD. [*Received, November 1st,* 1928.]

CCCCXXIII.—*Degradation of Quaternary Ammonium Salts. Part I.*

By THOMAS STEVENS STEVENS, ELTON MARSHALL CREIGHTON, ALEXANDER BROWN GORDON, and MALCOLM MACNICOL.



IN the course of synthetic work a method was required whereby the nitrogen atom of a secondary amine might be protected in such a way as to admit of quaternary salt formation and subsequent removal of the protecting group : the most obvious solution was the insertion of an alkyl radical which should be removed with special ease in a Hofmann degradation of the subsequently formed quaternary salt. Now quaternary salts derived from tetrahydro*iso*quinoline readily undergo such degradation with rupture of the bond between the nitrogen atom and carbon atom 3, but the conversion of narcotine methiodide (I) into narceïne (II) forms a notable exception. This fact suggested that the group $Ph\cdot CH(OH)\cdot CH_2\cdot$ might prove suitable.

Preliminary experiments showed that styrene iodohydrin did not readily yield quaternary salts, and accordingly salts were prepared from ω-bromoacetophenone and tertiary bases, and submitted to reduction with sodium amalgam. It is probable, however, that the removal of the phenacyl group under these conditions is not due to its reduction to β-hydroxy-β-phenylethyl and subsequent Hofmann degradation, for it was found that *phenacylbenzyldimethylammonium bromide* yielded benzyldimethylamine on reduction in *acid* solution, and similar observations have been recorded by Schmidt and Rumpel (*Arch. Pharm.*, 1899, **237**, 222) and by Emde and Runne (*ibid.*, 1911, **249**, 354). Emde's systematic study of the reduction of ammonium salts has shown that of the commonly occurring radicals benzyl is most loosely held, but it was necessary for the present purpose to find a still more easily detachable group.

The phenacylo-bromides or -iodides of β-phenylethyldimethylamine, dimethylpiperazine, hydrohydrastinine (III), benzylmethylamine, and α-phenylethyldimethylamine were investigated;

the first three salts readily lost the phenacyl group on reduction with sodium amalgam, but the last two reacted abnormally (*vide*

(III.)

infra). The results show that the removal of the phenacyl group by reduction may leave intact structures which exhibit little stability towards other methods of degradation. The satisfactory results obtained with the salt derived from dimethylpiperazine are of particular interest, since the piperazine ring is opened with exceptional ease by Hofmann degradation (von Braun, Goll, and Zobel, *Ber.*, 1926, **59**, 936).

When an aqueous solution of phenacylbenzyldimethylammonium bromide (IV) is treated with sodium amalgam, the reaction does not proceed normally with elimination of the phenacyl radical, but yields a solid base, $C_{17}H_{19}ON$, which is also produced in excellent yield by heating the salt (IV) with dilute sodium hydroxide solution. The analytical data are not inconsistent with the formula $C_{16}H_{17}ON$ (= Ph·CO·CH_2·NMe·CH_2Ph), but the degradation has not taken the unusual course of removing a methyl group preferentially to benzyl or phenacyl, since the *methobromide* of the new base is not identical with the salt (IV). Hot alkali converts this methobromide into phenyl styryl ketone, so that the solid base would appear to have the constitution (V) or (VI). The former alternative is favoured, and the presence of an $\alpha\gamma$-diphenylpropane skeleton confirmed, by the observation that the methobromide yields benzylacetophenone on reduction.

(IV.) Ph·CO·CH_2·NMe_2Br·CH_2Ph

(V.) Ph·CO·CH(·NMe_2)·CH_2Ph

Ph·CO·CH_2·CHPh(·NMe_2) (VI.)

Ph·CO·CHBr·CH_2Ph (VII.)

The formula (V) was shown by synthesis to be the correct one. Benzylacetophenone yields the substance (VII) on bromination, the position of the bromine atom being confirmed by the non-identity of the compound with the known β-bromobenzylacetophenone (Rupe and Schneider, *Ber.*, 1895, **28**, 958; Vorländer and Tubandt, *Ber.*, 1904, **37**, 1652). By the action of dimethylamine, (VII) yields a product identical with the base $C_{17}H_{19}ON$. The synthesis might conceivably give rise to the isomeride (VI) by removal of hydrogen bromide from (VII), followed by addition of dimethylamine to the unsaturated ketone, but experiments on the addition of dimethylamine to phenyl styryl ketone have yielded only small quantities

of very unstable basic material, in general agreement with the observation of Georgi and Schwyzer (*J. pr. Chem.*, 1912, **86**, 273) that β-piperidinobenzylacetophenone is highly unstable.

Phenacyl-α-phenylethyldimethylammonium iodide yields with alkali a presumably similar solid base which will be described in a future communication.

This peculiar migration of the benzyl radical is probably due to the combined effect of the relative toleration of the benzyl group for a positive charge (compare Hanhart and Ingold, J., 1927, 1003) and the reactivity of the methylene group in the phenacyl radical, but we prefer not to speculate further as to the mechanism of the reaction until more experimental data are forthcoming.

The fact that the substance (I) yields benzyldimethylamine on reduction in acid solution shows that the quaternary salt has the structure assigned to it, and that the migration takes place during the treatment with alkali.

Experimental.

The following tertiary bases were prepared according to the references quoted: β-phenylethyldimethylamine (Decker and Becker, *Ber.*, 1912, **45**, 2404), dimethylpiperazine (Eschweiler, D.R.-P. 80520, 1893; Knorr, Hörlein, and Roth, *Ber.*, 1905, **38**, 3136), benzyldimethylamine (Eschweiler, *loc. cit.*; Sommelet and Guioth, *Compt. rend.*, 1922, **174**, 687). The quaternary salts were obtained by refluxing the base (1 mol.) with bromoacetophenone (1 mol.) in benzene solution for ½—1 hour, except in the case of that derived from diethylaniline, the reaction here being carried out in hot alcohol or cold acetone. The bromide was either recrystallised from alcohol–ether, or converted by potassium iodide solution into the iodide, and the latter purified in like manner. Reduction of the salts was carried out in hot aqueous solution by an excess of sodium amalgam.

Phenacylphenyldiethylammonium iodide forms a microcrystalline powder, m. p. 133° (Found: I, 32·5. $C_{18}H_{22}ONI$ requires I, 32·2%). The preparation of this and other quaternary salts containing the nitrogen atom directly attached to an aromatic nucleus did not proceed smoothly (compare Wedekind, *Ber.*, 1908, **41**, 2802), and their degradation appeared to take an abnormal course, which is under investigation.

Phenacyl-β-phenylethyldimethylammonium bromide forms clusters of minute prisms, m. p. 191° (Found: Br, 23·2. $C_{18}H_{12}ONBr$ requires Br, 23·0%). After degradation, the β-phenylethyldimethylamine was identified as picrate and as methiodide (Decker and Becker, *loc. cit.*).

Diphenacyldimethylpiperazinium dibromide is rather sparingly soluble in water or alcohol, and crystallises from these solvents in small laminæ, m. p. 222—225° (decomp.) (Found: Br, 30·8. $C_{22}H_{28}O_2N_2Br_2$ requires Br, 31·2%). The salt appeared to be homogeneous, but no very thorough search was made for the second theoretically possible stereoisomeride. After reduction, the regenerated dimethylpiperazine was distilled in steam and isolated as the very sparingly soluble picrate (decomp. 280°) (Knorr, Hörlein, and Roth, *loc. cit.*). It was further characterised by the red precipitate produced with potassium bismuth iodide, and by reconversion, through the hydrochloride, into the original phenacylobromide.

Hydrohydrastinine phenacyloiodide separates from water or alcohol, in both of which it is sparingly soluble, in spherical aggregates of minute prisms, m. p. 190° (Found: I, 28·9. $C_{19}H_{20}O_3NI$ requires I, 29·1%). From the liquors after reduction, benzene extracted hydrohydrastinine, m. p. and mixed m. p. 64°.

Phenacylbenzyldimethylammonium bromide forms small prisms, m. p. 167—168° (Found: Br, 24·2. $C_{17}H_{20}ONBr$ requires Br, 24·0%). Reduction with zinc dust and sulphuric acid gave a steam-volatile base whose methiodide underwent partial fusion at 170° (m. p. of benzyltrimethylammonium iodide, 177—178°), but was not completely melted below 250°. With picric acid, however, the iodide yielded benzyltrimethylammonium picrate, m. p. and mixed m. p. 173—174° (Goss, Hanhart, and Ingold, J., 1927, 259, give 168—169°); the crude iodide probably contained phenacyltrimethylammonium iodide, or the tetramethylammonium salt produced from the latter by the action of excess of methyl iodide.

ω-Dimethylamino-ω-benzylacetophenone (V).—(*a*) Phenacylbenzyldimethylammonium bromide is heated on the water-bath with excess of 10% sodium hydroxide solution for 1 hour. The oily product solidifies on cooling and is recrystallised from aqueous methyl alcohol. Yield, 90%. (*b*) ω-Bromo-ω-benzylacetophenone (*vide infra*) (1 mol.), dimethylamine hydrochloride (2 mols.), and sodium methoxide (2 mols.) are mixed in methyl-alcoholic solution, kept over-night, and warmed for 2 hours on the water-bath. The diluted mixture is extracted with benzene and the product is extracted from the benzene by hydrochloric acid and precipitated by ammonia.

ω-Dimethylamino-ω-benzylacetophenone forms colourless leaflets, m. p. 77—79°, which are moderately easily soluble in methyl alcohol and readily soluble in benzene or light petroleum (Found: C, 80·7, 80·8; H, 7·4, 7·4; *M*, cryoscopic in benzene, 252. $C_{17}H_{19}ON$ requires C, 80·6; H, 7·5%; *M*, 253). The substance is slightly volatile in steam and slowly resinifies on keeping. It does not

appear to react with hydroxylamine, semicarbazide, or *p*-nitrophenylhydrazine, and is comparatively stable towards acid permanganate. The *picrate* crystallises from alcohol in bright yellow sword-blades, m. p. 147—149° (Found: N, 11·8. $C_{17}H_{19}ON,C_6H_3O_7N_3$ requires N, 11·6%). The identity of the products yielded by methods (*a*) and (*b*) was shown by direct comparison and mixed melting points of the base and of the picrate.

The methosulphate, prepared in benzene solution, yields the *methobromide* on addition of potassium bromide to its solution in water. This salt separates from alcohol–ether in faintly pink prisms, m. p. 195—197° (Found: Br, 21·9, 21·4; loss at 130°, 6·2. $C_{18}H_{22}ONBr,\frac{1}{2}C_2H_6O$ requires Br, 21·6; loss, 6·2%). On heating on the water-bath with dilute sodium hydroxide solution it yields phenyl styryl ketone, identified as the α-dibromide (Pond, York, and Moore, *J. Amer. Chem. Soc.*, 1901, **23**, 790), m. p. and mixed m. p. 157°. By reduction with zinc dust and sulphuric acid, the methobromide yields benzylacetophenone, which was characterised by conversion into the semicarbazone (most readily purified from ether–light petroleum), m. p. and mixed m. p. 143° (Jacobson and Ghosh, J., 1915, **107**, 962).

ω-Bromo-ω-benzylacetophenone (VII) is obtained by the action of the theoretical quantity of bromine on benzylacetophenone in carbon tetrachloride. The reaction proceeds rapidly, and after the hydrogen bromide has been removed by a current of dry air the solvent is evaporated and the residue recrystallised from methyl alcohol. It forms minute prisms, m. p. 57—59° (Found: Br, 27·8. $C_{15}H_{13}OBr$ requires Br, 27·7%); the m. p. is depressed by admixture with β-bromobenzylacetophenone, prepared by the method of Vorländer and Tubandt (*loc. cit.*). The substance (IV) appears to show the acidic properties associated with α-halogeno-ketones in that it yields a golden-yellow solution with aqueous-alcoholic alkali.

THE UNIVERSITY, GLASGOW. [*Received, October 27th*, 1928.]

CCCCXXIV.—*Studies in the Composition of Coal. The Active-decomposition Point of Coal.*

By RONALD HOLROYD and RICHARD VERNON WHEELER.

DURING the slow distillation of a bituminous coal in a vacuum, gases and liquids (water and oils) are evolved at quite low temperatures. At 100°, for example, traces of liquid pentane can be detected in the water which, together with "occluded" gases, may

be evolved in considerable quantity from an air-dried coal at that temperature. Such gases and liquids are not products of decomposition of the coal. Even the red oils that first make their appearance at about 225° are not decomposition products, but are liquated from the coal conglomerate, being yielded by free hydrocarbons. The main mass of the coal begins to decompose at a definite temperature which, for a given coal under standard conditions of heating, is constant within $\pm$ 2°. Wide variations in the experimental conditions do not markedly affect the result, but this temperature of active decomposition varies for different coals. Representing as it does the beginning of disruption by heat of the ulmin molecules, it would appear to be an important constant characteristic of the type and properties of different coals, and we have therefore determined it for a number of samples.

Before recording the results, we must recount the observations, referred to briefly in our paper on oil-yielding constituents (this vol., p. 2669), which enable this decomposition point to be specified and related to the ulmin constituents of the coal.

The method of experiment involved the heating of 250-g. charges of the finely powdered coals under high vacuum at different temperatures, the standard period of heating at each temperature being 120 hours. Under these conditions, the action of heat on the individual ingredients of the coal could be followed comparatively easily. No marked decomposition occurred with any bituminous coal below about 300°: as recorded in our previous paper, for example, Wigan Six Foot coal first began to decompose rapidly over the range 315—320°.

The characteristic products of this extensive decomposition during its early stages are, with all coals, water, phenolic oils (yielded exclusively by the ulmin constituents of the coals, see J., 1915, **107**, 1318), and gaseous paraffins. Prolonged heating of a coal just below its decomposition point yields only small quantities of these characteristic products, whilst prolonged heating just above it yields greatly enhanced quantities. This is well illustrated by the results recorded in Table I. With the Wigan Six Foot coal, parallel distillations were carried out at 300° and 320° during 120 hours (the "standard" period of heating) and at 310° and 325° during 750 hours.

In Table I, the italicised figures in particular relate to the active-decomposition point. The high yields of oils on prolonged heating at 310°—higher yields than during the "standard" distillation at 320°—require explanation. For the most part, these are not products of decomposition of the main mass of the coal, but, as will be demonstrated in another communication, are derived

from organised plant entities (mainly spore exines and cuticles), of which the Wigan Six Foot coal (mainly a clarain) contained about 4%. Such, in particular, are the unsaturated hydrocarbons. The oils soluble in ether and chloroform were derived from resins, which began to decompose slowly at 310°, whereas during the "standard" distillations they began to distil (with partial decomposition) at 325—330°.

The solid residues remaining after the distillation of coals at different temperatures undergo marked changes in character when the active-decomposition point has been passed. The principal changes in the residues are summarised in Table II, the Wigan Six Foot coal again being taken as an example.

TABLE II.

The Active Decomposition of Wigan Six Foot Coal. Solid Products.

	Sol. in C_5H_5N. Insol. in $CHCl_3$. (% on ash-free,	Sol. in $CHCl_3$. Insol. in light petroleum and Et_2O. dry coal.)	Reactivity with oxygen (c.c. per g.).	Behaviour on coking.
Original coal	12·34	3·14	11·1	Swollen
Residue at 250°	8·79	1·93	—	Less swollen
Residue at 280°	8·12	1·67	7·4	Shrunken
Residue at 300°	8·25	1·51	6·4	Shrunken
Residue at 320°	10·08	2·95	7·0	Much swollen
Residue at 350°	5·73	1·02	6·4	Incoherent

The material "soluble in pyridine but insoluble in chloro[illegible] (termed β-compounds in the original coal, and regarded [illegible]

compounds that are dispersed rather than dissolved by pyridine) decreases in quantity in the residues obtained at temperatures below the decomposition point, but suddenly increases when that point has been passed. Similar remarks apply to the material soluble in chloroform but insoluble in light petroleum and ethyl ether. This material (termed γ_3- and γ_4-compounds in the original coal) behaves in some respects like the resins (see Cockram and Wheeler, J., 1927, 700), but in others, as this, like the ulmins. Simultaneously, therefore, with a marked evolution of gases and liquids, such as are known to be yielded on the break-down of the ulmin molecules, there is a marked change in the behaviour of the residues towards solvents, suggestive of a more comprehensive disruption than that of external groupings from the molecules. At lower temperatures, external groupings may be split off from the ulmin molecules, yielding water and the oxides of carbon (particularly from a partially oxidised coal), and causing a gradual decrease in reactivity.

Similarly, as the temperature of distillation was raised, the reactivity of the residues with oxygen gradually decreased, to increase suddenly as soon as the point of marked decomposition had been passed. The reactivity measurements recorded in Table II (made for us by Dr. A. L. Godbert) are expressed in terms of the volume of oxygen combining with the material at 150° under standard experimental conditions. They confirm observations, made by Graham and Coles (*Fuel*, 1928, 7, 21), that the rate of oxidation of certain coals was considerably increased by preheating them in a vacuum at "critical" temperatures, between 300° and 400°, dependent on the character of the coals. These critical temperatures were, we conclude, the active-decomposition points of the coals. The compounds responsible for the reactivity of coal with oxygen have been shown by Francis and Wheeler (*Safety in Mines Research Board Paper* No. 28, 1926) to be the ulmin compounds.

Finally, the results of coking tests, carried out by heating in small crucibles at 900°, during 7½ minutes, 2-g. samples of the coals and residues from the distillations at different temperatures, revealed a marked change in this characteristic property of coal by preheating at the decomposition point, the coke produced from that residue being considerably more swollen than the coke from the original coal.

Such fundamental changes in the properties of the coal on being heated at a given temperature clearly mark the beginning of extensive molecular disruption. Francis and Wheeler (*loc. cit.*) conclude from their work that the nuclei of the ulmin molecules are compact systems of six-membered annular groupings connected together by

heterocyclic structures such as pyrrole and furan. Compounds having such structures might be expected to yield alkylised phenolic compounds and complex hydroaromatic hydrocarbons on decomposition (see Schrauth, *Brennstoff-Chem.*, 1923, **4**, 161). Such compounds have, in fact, been found to be characteristic decomposition products of the coal ulmins.

The Decomposition Points of Different Coals.

The active-decomposition points of a number of different coals, with data regarding the characteristic products of decomposition of most of them, have been determined. The results are summarised in Table III.

* Calculated on the "pure coal" basis; see Table IV.

† Vitrain portion. ‡ Durain portion.

In the descriptions of the coals, the name of the seam is given first, with the name of the colliery or pit at which the seam was worked in parentheses. All the coals except those specified were clarains. With the two durains, the decomposition point could not be determined precisely, since there was incipient decomposition of a minor ingredient of the coal at a lower temperature. It will be seen that, in general, the decomposition point increased with the carbon content of the coal, a result to be expected if the decomposition is that of the ulmin constituents. There is a general tendency for the yields of water and phenolic compounds (expressed in Table III as percentages on the ash-free, dry coals) to be greater from the coals of lower carbon content. The yields of oxides of carbon above the decomposition point were also greater from the coals of lower carbon content.

In a paper entitled "The Primary Decomposition of Coal. I.

The Temperature of Initial Decomposition," King and Willgress (*Dept. Sci. Ind. Res., Fuel Res. Tech. Paper No.* 16, 1927) record results for three bituminous coals showing that, when they were heated in a stream of nitrogen, traces of oils were carried over at lower temperatures from the coals of higher carbon content, as follows: C, 74·5%, first appearance of oil at 245°; C, 83·87%, 230°; C, 85·43%, 215°. They say: "With bituminous coals the temperature of initial decomposition appears to increase with increasing oxygen content and decreasing carbon content." We are satisfied that the temperature at which oils first make their appearance when a bituminous coal is heated is not the temperature of initial decomposition of the coal, but that such oils are distilled unchanged. In our experience, the temperature at which such oils

first appear bears no direct relation to the carbon content of the coal. It has, however, a tendency to be lower the greater the proportion of free hydrocarbons in the coal. Some decomposition of part of the coal substance undoubtedly occurs at a lower temperature than that specified as the "active-decomposition point." As already stated, the external groupings of the ulmin compounds may yield water and oxides of carbon in small amount at quite low temperatures (from about 150° upwards), whilst other parts of the coal conglomerate, such as the resins, spore exines, and cuticles, yield oils slowly at about 300°. Such decompositions do not materially affect the character of the coal, a loss of reactivity of the ulmin compounds being the most noticeable result. Marked changes of character only begin when the breakdown of the nuclear structure of the ulmin compounds begins.

Proximate, ultimate, and rational analyses of the coals referred to in this paper are given in Table IV. For the ultimate analyses, the usual calculations on an "ash-free, dry" basis have not been made; instead, allowance has been made for the fact that the mineral matter contained in a coal differs in composition and amount from the ash it yields on incineration. For the rational analyses, the methods described by Francis and Wheeler (this vol., p. 2967) were used.

NOTE.—Through an error in transcription, the figures in the first column of Table III of our previous paper (*loc. cit.*, p. 2675) were wrongly given. They should read: 81·54, 85·5, 86·1, 85·4, 79·0, 77·5.

The work described in this paper forms part of a research on the constitution of coal which we are carrying out for the Safety in Mines Research Board, to whom our thanks are due for permission to publish the results.

SAFETY IN MINES RESEARCH LABORATORIES,
SHEFFIELD. [*Received, October 23rd*, 1928.]

CCCCXXV.—*Explosions in Closed Cylinders. Part I. Methane–Air Explosions in a Long Cylinder. Part II. The Effect of the Length of the Cylinder.*

By WILLIAM ANTHONY KIRKBY and RICHARD VERNON WHEELER.

THE object of this research is the correlation of the movement of flame with the development of pressure during explosions in a closed cylinder the length of which is much greater than its diameter;

conditions which may be presumed to cause the movement of flame to differ considerably from that in a cylinder, the length and diameter of which are nearly equal, or in a sphere or cube, as in the experiments of Ellis and Wheeler (J., 1925, 127, 764; 1927, 153).

Similar work has been carried out by Woodbury, Lewis, and Canby (*J. Soc. Automotive Eng.*, 1921, 8, 209) with acetylene–air mixtures in a vertical cylinder 30·5 cm. long and 10·15 cm. in diameter. The mixtures were ignited at the base of the cylinder and simultaneous records were taken of the development of pressure and the movement of the flame as photographed through a window formed by a glass rod extending throughout the length of the cylinder. From the records it would appear that in each explosion the time of attainment of maximum pressure coincided with that

FIG. 1.

Explosion-cylinder and pressure gauge.

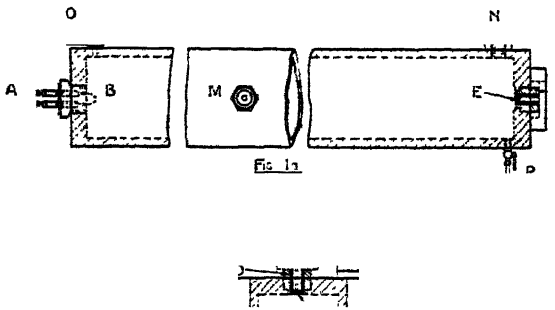

Fig. 1a

of the passage of flame through the mixture, whilst the time–pressure curves indicated arrests in the development of pressure simultaneous with arrests in the movement of the flame.

Morgan (*Proc. Inst. Auto. Eng.*, 1925, 15, 27; *Phil. Mag.*, 1927, 3, 1161) studied the development of pressure during explosions of coal-gas–air and methane–air mixtures in horizontal cylinders 4·45 cm. in diameter and either 30·5 or 61 cm. long, ignition being at one end. This work will be discussed more particularly in Part II, but the important point noted was the occurrence, under certain conditions, of strong and rapid vibrations at the crests of the time–pressure curves.

Method of Experiment.—The gun-metal cylinder (supported horizontally) is 200 cm. long and of 10 cm. internal diameter, its capacity being about 16 litres. Fig. 1*a* shows its two ends in cross-section and a side view of a portion of its length. At one end is an ignition plug, A, carrying platinum electrodes, B, projecting 1 cm.

into the cylinder and forming a spark-gap of 4 mm. The other end carries on a boss, C, a pressure recorder, shown in detail at Fig. 1*b*. The sleeve, D, of hardened steel, is screwed into the end of the cylinder, and the hollow piston, E, also of hardened steel, moves freely in it, being prevented from entering the cylinder by a thin collar. The movements of the piston under pressure developed by an explosion within the cylinder are transmitted to the apex of a strong triangular spring of tempered steel, F, by a loose steel link. The spring is clamped at its base, G, and its apex carries a thin strip of steel, K, with a scribing style, the movement of which is traced on a smoked-paper chart on a revolving drum mounted at L. At intervals of 20 cm. along the cylinder are plug fittings, one of which is shown at M (Fig. 1*a*), and another in cross-section at N, which are normally used for the insertion of circular windows of quartz, 6·3 mm. in diameter, through which the flame of an explosion as it passes can be photographed. For such photographs a camera with a quartz lens is used, with a revolving drum on which "Lumière" sensitised paper is wrapped. The plug fittings also serve on occasion for the introduction of screen-wires, whereby the passage of flame can be recorded electrically, or for firing-plugs, when it is desired to ignite the mixture otherwise than at the end of the cylinder. Valves at O and P allow of the evacuation of the cylinder and the admission of the explosive mixture.

In carrying out an experiment, the cylinder was filled with the required mixture, prepared beforehand in a gas-holder over glycerol and water. Ignition was effected by a single secondary discharge from an 8-inch induction coil, produced by breaking a current of 5 amps. in the primary circuit. The moment of ignition was recorded on both the pressure chart and the photographic paper, the speeds of revolution of both drums being obtained by means of a tuning fork of 50 frequency.

Results of Experiments.

A. Ignition at One End of the Cylinder.—When ignition was at one end of the cylinder, the time taken for the flame to travel throughout its length, in all the mixtures of methane and air studied, corresponded with the time of attainment of maximum pressure recorded by a manometer at the far end. The time at which the flame reached the far end of the cylinder was recorded either (*a*) by the fusion of a fine screen-wire of copper or (*b*) photographically (at a window 1·0 cm. from the end). The results are given in Table I.

The speed of flame. The mean speed of propagation of [illegible] over the 200-cm. length of the cylinder was for all mixtures [illegible] siderably faster than the mean speed from the centre to the wall of

TABLE I.

Explosions of Methane–Air Mixtures in a Cylinder.

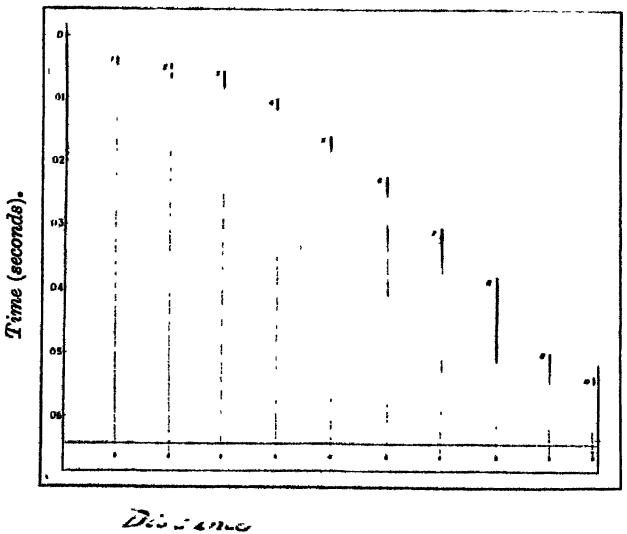
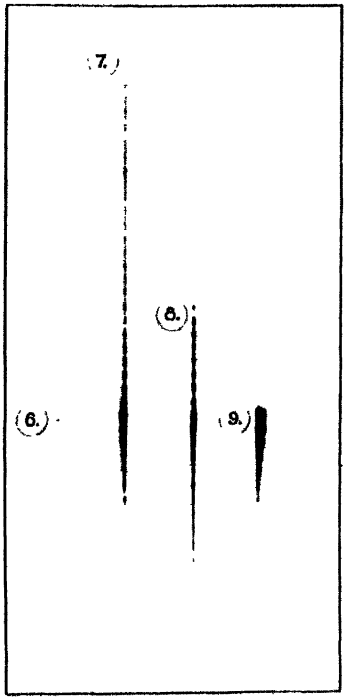
a sphere of 15·6 cm. radius (Wheeler, J., 1918, **113**, 840); thus, for a 9·8% mixture the mean speed was 410 cm. per sec. as compared with 144 cm. per sec. for the sphere. In a sphere, with central ignition, the flame moves at a nearly uniform speed until it approaches the walls. In a long cylinder, on the other hand, the progress of the flame is by no means uniform, and measurements of the mean speed over the whole distance have little significance. This is illustrated by the photographic analysis of the movement of flame in a 9·7% methane–air mixture reproduced at (1) on Plate I (much reduced in size).



From the times at which the flame first appeared at each window, the mean speed over each successive length of 20 cm. can be calculated. Calculations for mixtures containing 9·6 and 10% of methane are recorded in Table II.

TABLE II.



Speed of Flame in a Long Cylinder.

Distance (cm.).	Speed (cm. per sec.). 9·6% CH_4.	10·0% CH_4.	Distance (cm.).	Speed (cm. per sec.). 9·6% CH_4.	10·0% CH_4.
0— 20	800	1000	100—120	300	333
20— 40	2000	2000	120—140	210	281
40— 60	1165	1000	140—160	196	181
60— 80	715	500	160—180	181	162
80—100	345	317	180—200	500	385

These results, which are typical of the most explosive mixtures of methane and air, show that at the outset the flame darts forward at a rapidly increasing speed. A retardation then occurs, and becomes

(1)
Explosion of a 9·7% methane–air mixture. Flame at windows along 200-cm. cylinder.

(2)
Similar explosion to (1), *showing deta of flame at windows* 6 *to* 9.

[To face p. 3506]

most marked by the time the flame has travelled about one-third of the length of the cylinder. A comparatively slow speed is then maintained until within 20 cm. of the end of the cylinder, whereupon the flame moves forward more rapidly. The majority of the photographs show that the flame assumes a vibratory character at the end of its travel. In some photographs, vibrations also appear after the flame has travelled half-way along the cylinder. For mixtures containing from 9·5—10·0% of methane, the frequency of the later vibrations, which are always strongly marked (see 2, Plate I), is about 200. When vibrations occur midway along the cylinder, their frequency is about 115.

The development of pressure. In a spherical vessel with central ignition, the flame in mixtures of methane and air containing between 7 and 11% of methane reaches the wall simultaneously at all points, so that the whole of the mixture is inflamed before any appreciable cooling can take place. In a long cylinder, on the other hand, with ignition at one end, part of the flame touches the walls long before propagation is complete, and cooling of products of combustion begins at an early stage. The rate of development of pressure can therefore be expected to be slower than in a sphere, and the maximum pressure to be lower. In Table III the maximum pressures (above atmospheric) recorded for a number of mixtures of methane and air (*a*) in a 16-litre sphere (with central ignition) and (*b*) in the cylinder (capacity about 16 litres) are compared.

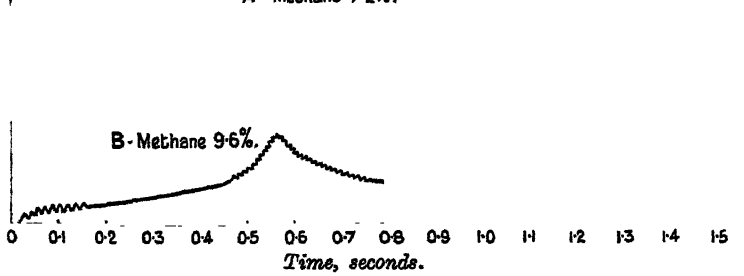
9·80	6·94	4·00			

The time–pressure records were of two types, dependent on the composition of the mixture. If the mixture contained less than 8 or more than 11% of methane, smooth curves of the type reproduced at A, Fig. 2 were obtained. With 8—11% of methane, the curves showed marked vibrations at their crests (see B, Fig. 2). These vibrations had the same frequency, about 200, as those of the flame as it reached the end of the cylinder. Indeed, the development of pressure throughout corresponded closely with the movement of the flame, as the time–pressure and time–distance curves



reproduced in Fig. 3 illustrate. Both curves relate to a 10% methane–air mixture, the former showing the development of pressure up to the time of its maximum, and the latter the time of passage of the flame from end to end of the cylinder.

Correlation of Flame-movement with Pressure-development.

When comparing the time–pressure and the time–distance curve in Fig. 3, it must be remembered that the latter was obtained from records of the passage of flame at small windows 20 cm. apart. Between any two windows, fluctuations in the movement of the flame may have occurred of which no record was obtained. Nevertheless, the two curves correspond closely in character and exhibit the following features.

FIG. 2.

Typical time–pressure curves.

(*a*) A rapid rise in pressure, shortly after ignition, corresponding with a rapid movement of flame over the first 20 or 30 cm. During this stage, there is but little cooling of the products of combustion, since the flame moves rapidly along the axis of the cylinder and but a small part of its surface comes in contact with the walls (see Part III, following paper).

(*b*) An arrest in pressure-development, corresponding with an arrest in flame-movement. At this point the "skirt" of the flame (see Part III) comes in contact with the walls of the cylinder. Following this arrest, both the movement of the flame and the development of pressure are comparatively slow over a distance of about 150 cm.

(*c*) A rapid rise in pressure to a maximum as the flame moves rapidly towards the end of the cylinder. Rapid vibrations (omitted from Fig. 3) are shown by both the pressure curves and the flame photographs.

(*d*) At any moment before the flame has travelled throughout the mixture, the fraction of the total distance travelled is greater than the fraction of the total pressure development. Hence the

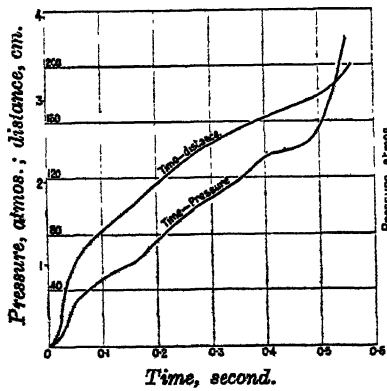
flame surface, so long as it is not vibratory, must be advanced along the axis of the cylinder, tailing off towards the walls.

B. Position of Point of Ignition varied.—A series of experiments was made, with mixtures containing between 9·5 and 9·8% of methane, in which the position of the point of ignition was varied. To effect this, the ignition plug was removed from the end of the cylinder and screwed into one or other of the window holes disposed along its length, the electrode points, 4 mm. apart, being carried to the horizontal axis of the cylinder.

Measurements were made of the times taken for the flames to reach each end of the cylinder, of the maximum pressure recorded by a gauge fixed at the end nearer the point of ignition, and of the

FIG. 3.

Comparison of time-pressure and time-distance curves.



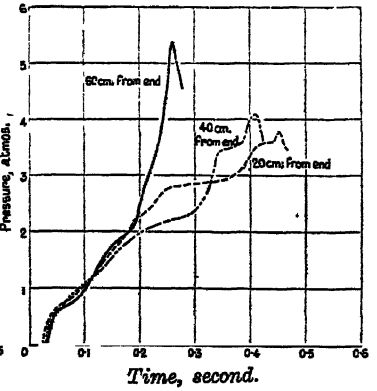


FIG. 4.

Point of ignition varied.

time of attainment of this maximum pressure ("time of explosion"). The results are summarised in Table IV, in which the end of the cylinder to which the pressure gauge was attached is termed A, and the other end B.

In each experiment the maximum pressure was recorded at the moment when flame had reached the end of the longer limb of the cylinder. Unless there was considerable disparity in length between the two limbs, there was a marked tendency for the flames travelling to right and left from the point of ignition to reach the ends of the cylinder simultaneously, and the attainment of maximum pressure could then be said, in general, to synchronise with the complete inflammation of the mixture.

When ignition was effected at a distance of about 40 cm. or [illegible] from one end of the cylinder, the flame reached the near end, [illegible] extinguished with consequent rapid cooling of the products of com-

Measurements uncertain owing to vibrations.

bustion, some time before it reached the far end. For this reason the maximum pressure attained was less than when ignition was at the middle. For the same reason, the maximum pressure increased in magnitude as the point of ignition was moved towards the middle of the cylinder, whilst the interval between ignition and the attainment of maximum pressure decreased. The maximum pressure recorded when ignition was at the middle of the cylinder was higher than when ignition was at one end. The three curves reproduced in Fig. 4 represent the rate of rise of pressure when ignition was at a point 20, 40, or 60 cm. from one end of the cylinder.

C. Simultaneous Ignition at Two Points.—A series of experiments was made in which methane–air mixtures containing between 9 and 10% of methane were ignited at some point along the cylinder and at one end simultaneously, a pressure gauge being fixed at the opposite end. The object was to determine whether a higher pressure would be attained than that recorded when ignition was solely at the middle of the cylinder. The results are summarised in Table V.

Typical time–pressure curves are reproduced in Fig. 5, and from curves A, B, and C it will be seen that the rate of rise of pressure to the maximum became more rapid as the second ignition point was moved nearer to the middle of the cylinder (100 cm. from end A). The initial rate of development was then more rapid than with single ignition in any position. When the second ignition point

was 20 cm. from end A (curve A), there was a long period during which the rate of development of pressure was very slow, and the pressure ultimately attained was considerably lower than when ignition was solely at one end of the cylinder. The maximum pressure with double ignition was obtained when ignition was at one end and at the middle of the cylinder, but this pressure was lower than when ignition was at the middle of the cylinder only.

FIG. 5.

Dual ignition (distances are those of second ignition plug from end plug).

The important factor with respect to the production of pressure on explosion of a given mixture in a long cylinder is the time taken for the flame to travel throughout the mixture. When the mixture is ignited simultaneously at two points, the movement of one flame affects the movement of the other, hindering its development (see Part III). It thus results that the inflammation takes longer to complete when two flames are started simultaneously within the cylinder than when flame spreads from one point along the cylinder only. The three time–pressure curves (B, C, and E in Fig. 5) for explosions started simultaneously at one end of the cylinder and at 60, 100, or 180 cm. from that end, illustrate the retardation of the flames moving towards each other, for the period of maximum pressure is prolonged to a remarkable extent (0·04 to 0·09 sec.) corresponding with the slow approach of the flames.

Part II. The Effect of the Length of the Cylinder.

With a 200-cm. cylinder (10 cm. in diameter), it has been shown that in all explosions of methane–air mixtures containing 8—11% of methane, ignition being at one end of the cylinder, the flames became strongly vibratory towards the end of their travel. In earlier experiments with a cylinder of the same diameter but only 50 cm. long, no such vibrations were observed during the explosion of any mixture of methane and air. This accords with observations by Morgan to which reference was made in Part I. An explosion of coal-gas and air in a steel tube 4·45 cm. in diameter and 61 cm. long (ignition being at one end) was strongly vibratory, whereas an explosion of the same mixture in a similar tube of half the length showed no vibrations. Morgan considered the vibrations to be due to two interdependent factors—the rate of heat generation at the flame front and the vibration frequency of the gas space in the explosion vessel.

In order to study this matter more closely, by determining the limit at which an explosion becomes vibratory, arrangements were made for altering the length of our cylinder at will, by means of a piston that could slide within the cylinder and be locked in any position, the piston-head forming a pressure-tight end-plate. The ignition plug was at the centre of the piston-head, and the pressure gauge at the other end of the cylinder. On exploding mixtures of methane and air containing about 9·5% of methane, records were obtained of the maximum pressure developed (P, in atms.), the time of attainment of maximum pressure (T_m), and the time (T_f) taken for the flame to travel throughout the cylinder, the length (l) of which was varied between 2·5 and 200 cm. Some of the results are recorded in Table VI.

TABLE VI.

Explosions of a 9·5% Methane–Air Mixture in Cylinders of Different Lengths (10 cm. diam.).

50	5·5	0·20	—	180	4·0	0·49	—
60	5·3	0·24	0·20	200	4·0	0·55	

The critical length of cylinder for the production of a vibratory explosion with a 9·5% methane–air mixture was 140 cm. With shorter lengths, the movement of flame and the rate of production

of pressure were regular, the time–pressure records being characterised by a steady period of maximum pressure lasting from 0·005 sec. for a cylinder 3·5 cm. long to 0·03 sec. when the length was 120 cm. All such explosions were quite silent. When the cylinder was 140 cm. long, or longer, rapid vibrations were usually developed by the flames towards the end of their travel, and, synchronising with these vibrations, the time–pressure records (*e.g.*, B, Fig. 2) showed fluctuations at their crests. All such explosions were accompanied by a shrill screech.

When the explosion was vibratory, the time of attainment of maximum pressure ("time of explosion"), which always corresponded closely with the time taken for the flame front to travel throughout the cylinder, varied as between one experiment and another, performed under what were intended to be identical conditions, within fairly wide limits. For example, when the cylinder was 160 cm. long, the time of explosion was 0·466, 0·596, 0·565, and 0·483 sec. in successive experiments. It would seem that the moment at which vibrations were induced (and the subsequent course of the explosion thereby determined) was affected by slight inadvertent changes in the experimental conditions such, *e.g.*, as the condition of the inner walls of the explosion vessel. Similarly, a slight intentional change in the experimental conditions would transform a silent explosion into a noisy and vibratory one. A 6·85% methane–air mixture, initially at atmospheric pressure, exploded in the 200-cm. cylinder (ignition being at one end), was always silent and non-vibratory (time of explosion, 1·56 sec.), but when the initial pressure was increased to 3·6 atm. (absolute) the explosion was vibratory (time of explosion, 1·95 sec.). Similar results for pentane–air mixtures have been recorded by Maxwell and Wheeler (*J. Inst. Pet. Tech.*, 1928, **14**, 175).

The vibrations that occur, following the "uniform movement," when an explosive mixture is ignited at the open end of a long tube closed at the other end, have been shown by Mason and Wheeler (J., 1920, **117**, 36) to be due to resonance in the column of gases ahead of the flame, their frequency corresponding with that of the fundamental tone of the tube. The same explanation can apply to these closed-tube vibratory explosions, although on what the establishment of resonance depends is not clear. Morgan's (*loc. cit.*) suggestion, which appears to be accepted by Egerton and Gates (*Proc. Roy. Soc.*, 1927, *A*, **116**, 524), that the rate of heat generation at the flame front is the main factor involved, receives support from the fact that in a cylinder 120 cm. long the explosion of a 6·75% ethane–air mixture (time of explosion, 0·215 sec.) is vibratory, whereas that of a 9·5% methane–air mixture (time of explosion,

0·386 sec.) is not. On the other hand, some of Maxwell and Wheeler's (*loc. cit.*) results are at variance with this suggestion, for they found that, under the same conditions of experiment, the explosion of a 3·5% pentane–air mixture (time of explosion, 0·19 sec.) was vibratory, whereas that of a 2·95% benzene–air mixture (time of explosion, 0·17 sec.) was not. It would seem reasonable to believe that with a given explosive mixture, say a 9·5% methane–air mixture, the establishment of resonance in the column of gases ahead of the flame would depend, *ceteris paribus*, upon the rapidity with which the column was compressed. Thus it would depend upon the speed acquired by the flame front, which in turn would depend on the length of the cylinder. When explosions of different gases under the same conditions are compared, however, this explanation is insufficient. We believe the character of the reactions taking place behind the flame front to have an important bearing on the matter; we are now investigating this subject.

The relationship between the time of explosion and the length of the cylinder (for 9·5% methane–air mixtures) is shown in Table VI. There was close correspondence between the time of explosion and the time of passage of flame when the explosions were vibratory, *i.e.*, when the cylinder was 140 cm. long or longer. In the shorter cylinders, the flame front, travelling without vibrations, apparently reached the end before the attainment of maximum pressure. This is explicable by reason of the shape of the flame front which, when travelling in a horizontal tube, is inclined, the upper portion being in advance. After the flame has appeared at a window at the end of the horizontal axis, it still has to travel into the lower portion of the tube.

The time of explosion does not increase proportionally with the length of the cylinder, as it would if the mean speed of the flame were constant, but is less by so much as the mean speed of the flame is greater in the longer cylinders. This greater speed is due to the greater freedom of movement, at the outset of the explosion, of the unburnt gas ahead of the flame in the longer cylinders (see Part III), the conditions during the early stages of the spread of flame approximating more and more to those of constant pressure as the length of the cylinder is increased.

We wish to thank Mr. W. A. Batley, M.Sc., of the Department of Fuel Technology of Sheffield University, for considerable help with the experiments described in this paper. This work has been carried out for the Safety in Mines Research Board, to whom our thanks are due for permission to publish the results.

SHEFFIELD. [*Received, September 17th*, 1928.]

CCCCXXVI.—*Explosions in Closed Cylinders. Part III. The Manner of Movement of Flame.*

By Oliver Coligny de Champfleur Ellis and Richard Vernon Wheeler.

Some of the phenomena of explosions of methane and air in closed cylinders described in Parts I and II (preceding paper) can be explained by a study of the movements of flames under similar conditions by means of "snapshot" photographs on a stationary plate (see J., 1925, **127**, 760). In the examples reproduced in this paper, the flames are of carbon monoxide with oxygen, because their high actinic value renders them so serviceable for photographic analysis. The manner of movement of flame in mixtures of methane and air is essentially the same.

Ignition at One End of the Cylinder (compare Part I, A).—The photographs reproduced on Plate I are successive snapshots, at equal intervals of 4·1 millisecs. after ignition, of flame travelling in a mixture $10CO + O_2$, saturated with water vapour at 13·5°, after ignition at the centre of one end of a glass cylinder, 2·5 cm. in diameter and 20·3 cm. long, closed at both ends by rubber pads. The speed of flame in this mixture is comparable with that in a 9·5% methane–air mixture.

In the first snapshot, the flame appears as a small hemisphere centred on the point of ignition. In Fig. 2, no part of the tubular flame surface has as yet made contact with the walls of the cylinder, but its domed front has made rapid progress along the axis. In Fig. 3, the domed front has travelled still further, but the fringe of the luminous "skirt" has been extinguished. In Fig. 4, and thereafter, only the front portion of the flame surface remains, and that has changed its shape, having been turned inside-out owing to the sudden cooling of products of combustion behind it when the whole of the "skirt" came in contact with the walls of the cylinder.

The rapidly increasing speed of flame and development of pressure during the early stages of the explosion, remarked upon in Part I, are thus seen to be due to the increasing area of flame surface; the marked retardation and subsequent comparatively slow movement of flame and development of pressure are due to the sudden decrease in the area of the flame surface, consequent on the contact of all but its front with the walls of the cylinder, and to the sudden increase in the area over which the products of combustion are cooling. Although discussion of the matter is outside the scope of the present paper, we should mention that we regard the initial retardation of movement of the flame surface as being due to the retarding [illegible]

movement of the medium in which it is travelling. This initial retardation is accentuated by the sudden cooling of the products of combustion behind the flame surface (see *Fuel*, 1928, **7**, 195; compare Payman, *Proc. Roy. Soc.*, 1928, *A*, **120**, 90).

The individual snapshots of Plate I, together with subsequent snapshots at equal intervals until the flame had wholly expired, are shown as a composite photograph on Plate II. A record of the same flame taken on a revolving film is reproduced for comparison. The sudden retardation in the progress of the flame occurred when it had travelled about one-third of the length of the cylinder. Thereafter, its speed was nearly uniform until it reached the end. In this respect the explosion of $10CO + O_2$ in this comparatively short cylinder differed from the 9·5% methane–air explosions in a cylinder 10 cm. in diameter and 200 cm. long (described in Part I), inasmuch as in the latter the flames exhibited vibrations, and an increased speed, towards the end of their travel. In a glass cylinder 2 cm. in diameter and 40 cm. long, the flames in the mixture $10CO + O_2$ sometimes vibrated.

Position of Point of Ignition varied (compare Part I, B).—The effect of varying the point of ignition is illustrated in Figs. 1, 2, and 3 on Plate III. For these experiments the cylinder was 2 cm. in diameter and 40 cm. long, and the explosive mixture used was $10CO + O_2$. Ignition, on the axis of the cylinder, was at one end (Fig. 1), at the middle (Fig. 2), and midway between the middle and one end (Fig. 3). With ignition at the middle, the flame surfaces vibrated, and their mean speed increased, towards the end of their travel. The flame surface, being a mobile source of pressure in an enclosed space, tends to centre itself within the cylinder, so that when ignition is not at the middle it moves most rapidly towards the region of greatest volume. Cooling does not occur until the flame surface touches the walls, but, owing to its elongated shape at that moment (see Fig. 3, Plate III), cooling is then considerable. For this reason, and because of the sudden diminution in area of the flame surface, there is a sudden retardation in the movement of the flame (and in the development of pressure). The flame continues to propagate on two fronts (so that the rate of production of pressure tends to be double what it is when ignition is at one end of the cylinder), travelling faster towards the farther than towards the nearer end. It expires first at the nearer end, the system at that moment suffering both a reduced production of energy and an increased dissipation due to cooling. The speed of the remaining flame surface is therefore retarded. It thus results that, although when ignition is asymmetric the two flame surfaces nearly reach the two ends of the cylinder simultaneously, there is a comparatively

long interval between the expiration of the flame at the nearer end and its final expiration at the farther end. The more asymmetric the point of ignition, the greater is this interval, and the less, in consequence, is the maximum pressure developed.

Simultaneous Ignition at Two Points (compare Part I, C).—When an explosive mixture within a cylinder is ignited simultaneously at two points, not too close together, the initial rate of rise of pressure should be twice as fast as with single ignition unless the two flames hinder each other's development. Actually, the two flames do hinder each other, each developing a smaller surface area in a given time than it would if the other were absent. This is illustrated in Fig. 4, Plate III, which is a composite photograph of three successive snapshots, at equal intervals of 9·63 millisecs. after ignition, of flames in a mixture $13CO + O_2$, saturated with water vapour at 14°, contained in a closed horizontal glass tube 4 cm. in diameter and 32 cm. long. The mixture was ignited simultaneously at the middle of the cylinder and midway between the middle and one end. The two continuous flame surfaces tend to dispose themselves symmetrically. That on the left centres itself within the left-hand half of the tube, not within the tube as a whole as it would tend to do if it were alone. The right-hand flame surface moves bodily towards the right.

When contact occurs between the flame surfaces and the walls of the cylinder, the area of contact is nearly twice that when ignition is at one point only, and the rate of cooling is nearly twice as great. The net rise of pressure subsequently is therefore small, though the pressure is maintained from four sources whereas with single ignition there are but two. Figs. 5, 6, and 7 on Plate III are single snapshots (taken, respectively, 48·15, 57·78, and 62·59 millisecs. after ignition) of the flame surfaces after contact with the walls of the cylinder had occurred. They show the remarkably slow approach of the two inner flame surfaces towards each other.

With a 25% carbon monoxide–air mixture, saturated with water vapour at 11·8°, a number of experiments were made with different conditions of ignition in a glass cylinder 6 cm. in diameter and 32 cm. long. The durations of the flames under these different conditions are recorded in Table I.

The shortest duration of flame was thus with symmetrical double ignition at such a distance from the ends of the cylinder that there is no initial cooling; and the longest was with single-end ignition.

The Effect of the Length of the Cylinder (compare Part II).—Fig. 1 on Plate IV shows a succession of snapshots, at intervals of 4·1 millisecs. after ignition, of the flame in a mixture 10C[illegible] saturated with moisture at 15°, ignited at the end of a vertical [illegible]

cylinder, 5·0 cm. in diameter and 17 cm. long. The cylinder was placed vertically to secure symmetry of the flame surfaces and thus render their movement during the later stages clearer than it is when the cylinder is horizontal (see, *e.g.*, Fig. 1, Plate III). Fig. 1, Plate IV, should be compared with Figs. 2 and 3, for which the conditions of experiment were identical save that the cylinder was reduced in length to 12 cm. (Fig. 2) and 9·5 cm. (Fig. 3). It is evident that the greater the length of the cylinder the more freely does the flame surface move along its axis. It is evident, also, that at the moment when the flame surface has made contact with the walls, and rapid cooling of the products of combustion has begun, a greater proportion of the mixture has been burnt in the shortest than in the longest cylinder, so that a higher maximum pressure would be recorded in the former.

The experiments described in this paper were carried out in connexion with work that we are doing for the Safety in Mines Research Board, to whom our thanks are due for permission to publish these results.

SAFETY IN MINES RESEARCH LABORATORIES,
SHEFFIELD. [*Received, September 17th*, 1928.]

CCCCXXVII.—*Acid and Salt Effects in Catalysed Reactions. Part XVIII. The Dynamics of Autocatalysed Ester Hydrolysis.*

By HARRY MEDFORTH DAWSON and WILLIAM LOWSON.

RECENT experiments by the authors (this vol., p. 2146) have shown that the initial speed of the hydrolysis of ethyl acetate with hydrochloric acid as catalyst is proportional to the concentration of the acid when this is varied between 0·0002 and 0·2 mol. per litre. If

the concentration of the hydrochloric acid is less than 0·01 mol. per litre, the course of the reaction is modified by the catalytic action due to the acetic acid produced. The relative importance of this autocatalytic effect increases as the concentration of the hydrochloric acid diminishes, and it is not possible in practice to determine the initial velocity of the reaction when this concentration falls below 0·0002 mol. per litre.

The present experiments are, for the most part, concerned with the course of the reaction when foreign catalysts are absent, *i.e.*, when the only catalytic effects involved are those which are attributable, directly or indirectly, to the solvent or to the acetic acid which is set free in the reaction. In this connexion, reference should be made to the experiments of Wijs (*Z. physikal. Chem.*, 1893, **11**, 492; **12**, 514) on the autohydrolysis of methyl acetate, in which the progress of the reaction was followed by measurements of the electrical conductivity of the solution, and it was shown that the reaction velocity passed through a minimum value. The observations were, however, confined to a very small period in the early stages of the reaction, but this was sufficient for the main object of the experiments, which was to obtain a value for the ionisation constant of water.

In its entirety, the autocatalytic hydrolysis of an ester such as ethyl acetate represents a complex process in which the reaction velocity passes through a minimum and a maximum value. The attainment of maximum velocity is not in any way connected with the reversibility of the reaction, although this alone would of course suffice to determine the incidence of a maximum. If, however, the reverse reaction has to be taken into account, the mathematical treatment of the problem becomes extremely complex, and for this reason the investigation has been confined to that phase of the complete reaction for which the influence of the oppositely directed esterification process can be neglected. Within these limits, and in accordance with current views relating to catalytic effects, the general equation for the reaction velocity may be written

$$dx/dt = \{k_h[H^+] + k_{OH}[OH^-] + k_w[H_2O] + k_a[Ac^-] + k_m[HAc]\}(a - x)[H_2O] \quad . \quad . \quad (1)$$

in which the catalytic coefficients are represented by the usual symbols and $(a - x)$ is the concentration of the ester after time t. Since the concentrations of the several catalytic entities are connected by $[H^+].[OH^-] = K_w$, $[Ac^-] = [H^+] - [OH^-]$, and $[HAc] = x - [Ac^-]$, equation (1) may be written

$$dx/dt = \{(k_h - k_m + k_a)[H^+] + (k_{OH} + k_m - k_a)K_w/[H^+] + k_w[H_2O]\}(a - x)[H_2O],$$

and from a consideration of the relative values of $k'_h = 6{\cdot}5 \times 10^{-3}$, $k'_{OH} = 6{\cdot}5$, $k'_m = 1{\cdot}5 \times 10^{-6}$, $k'_a = 2 \times 10^{-7}$, and k'_w, which is too small to have a measurable value assigned to it, it may be readily shown that the equation may be further reduced to the form

$$dx/dt = \{k'_h[H^+] + k'_{OH}K_w/[H^+]\}\ (a - x) \quad . \quad . \quad (2)$$

where $k'_h = k_h[H_2O]$ and $k'_{OH} = k_{OH}[H_2O]$.

In terms of this equation it is convenient to distinguish two successive stages of the autocatalysed reaction. In the first stage the catalytic effect corresponds with the joint action of the hydrogen and the hydroxyl ion, and the concentration of the ester is practically constant. In the second stage the catalytic action is confined to the hydrogen ion, and the concentration of the ester gradually diminishes. There is, of course, no breach of continuity in passing from the first to the second stage, but it is convenient, although more or less arbitrary, to select as the end of the first stage that point at which the catalytic effect of the hydroxyl ion has fallen to 1% of the catalytic effect due to the hydrogen ion.

Before proceeding to the further examination of equation (2), reference may be made to the nature of the experimental observations. The solution of the ester (40 c.c. per litre = $0{\cdot}412M$) was prepared by dissolving carefully purified ethyl acetate in conductivity water, the temperature being kept at 25·0°. The acetic acid formed was determined after suitable time intervals by titration. In the early stages of the reaction, 25 c.c. samples were titrated with $0{\cdot}01N$-alkali, and in the later stages, 10 c.c. samples with $0{\cdot}1N$-alkali.

The earlier experiments showed wide differences in the results obtained; for instance, the time required for the production of acetic acid in $0{\cdot}0002M$ concentration varied from about 3000 to 10,000 minutes. Investigation of the cause of these discrepancies showed that the slower speeds of the reaction were mainly, if not entirely, due to the retarding effect of alkali from the walls of the glass containing vessel. The later experiments were therefore carried out in fused silica vessels, and it was thus possible to obtain reproducible results without difficulty. In order to acquire information relative to the influence of small quantities of alkali, parallel experiments in silica flasks were made with ester solutions to which various small quantities of sodium hydroxide were added. It may be readily shown that the hydroxide is rapidly converted into acetate, and that the course of the reaction as represented by the x–t curve is sensibly the same as if the equivalent amount of sodium acetate had been added at the outset.

In the actual application of equation (2), it has been found convenient to express the hydrogen-ion concentration of the acid solution in terms of the ionisation constant of the acid. If $[H^+] = rK$, then $[HA] = r^2K$, and the total concentration of the acid is $r(r + 1)K$. This quantity r may be termed the ionisation ratio, the relation of which to the degree of ionisation is given by $r = (1 - \alpha)/\alpha$ or $\alpha = 1/(r + 1)$. In terms of r, the expression for the ionisation constant takes the form $K = c/r(r + 1)$, where c is the total acid concentration.

First Stage of the Autocatalysed Reaction.—The quantity of acetic acid formed at the end of the first stage is far too small to be determined titrimetrically and our concern with this stage is therefore limited to the estimation of the period of time which it occupies. The equation for the reaction velocity is

$$dx/dt = \{k'_h[H^+] + k'_{OH}K_w/[H^+]\}\, a \quad . \quad . \quad . \quad (3)$$

and when the acid produced by the reaction is fully ionised, or $[H^+] = x$, this can be integrated quite simply (compare Dawson, J., 1927, 458). This, however, is no longer the case when the acid formed is weak and its hydrogen-ion concentration is given by $[H^+] = \sqrt{(K/2)^2 + Kx} - K/2$; in these circumstances the procedure followed in the calculation of the required time involves considerations which are associated with the catenary form of the v–log $[H^+]$ curve. The method employed is general in the sense that it may be applied in the case of all autocatalysed reactions of similar type.

The hydrogen-ion concentration at which the reaction velocity passes through its minimum value is given by $[H^+]_i = \sqrt{k'_{OH} \cdot K_w/k'_h}$, and if K_w is taken as 10^{-14}, we obtain $[H^+]_i = 0{\cdot}32 \times 10^{-5}$, or since the value of K for acetic acid in 0·4M-ethyl acetate solution is $1{\cdot}6 \times 10^{-5}$, $[H^+]_i = 0{\cdot}2K$, or $r_i = 0{\cdot}2$.

If the hydrogen-ion concentration is expressed in terms of $[H^+]_i$ such that $[H^+]/[H^+]_i = n$, then equation (3) may be written as

$$dx/dt = k'_h[H^+]_i(n + 1/n)a \quad . \quad . \quad . \quad . \quad (4)$$

according to which 99% of the total catalytic effect is due to the hydrogen ion when $n = 10$, *i.e.*, when $[H^+] = 2K$. The value $r = 2$, which corresponds with $x = 6K$, may thus be identified with the end of the first stage of the reaction. For the calculation of the time required to reach this point, the complete stage may be divided into a series of small intervals, Δt, for each of which $\Delta x = \Delta r(r + 1)K = K\Delta q$, where q measures the concentration of the acid in terms of K. If, now, $\bar{v}$ is the mean velocity for the interval

characterised by the mean reduced hydrogen-ion concentration $\bar{n}$, then according to equation (4) we have

$$\Delta t = \Delta x/\bar{v} = K\Delta q/[k'_h[H^+]_i(\bar{n} + 1/\bar{n})a]$$

Substituting $a = 0{\cdot}412$, $k'_h = 6{\cdot}5 \times 10^{-3}$, and $[H^+]_i = 0{\cdot}2K$, we have

$$\Delta t = 1870\Delta q/(n + 1/\bar{n}),$$

whence the time required for the first stage is given by

$$t_1 = 1870\Sigma_{q=0}^{q=6}\Delta q/(\bar{n} + 1/\bar{n}) \quad . \quad . \quad . \quad . \quad (5)$$

in which $\bar{n} = \bar{r}/r_i$ where $\bar{r}$ is the mean value of r for the interval for which the mean reduced hydrogen-ion concentration is $\bar{n}$. The smaller the values of Δt and Δq, the greater will be the accuracy of t_1 given by equation (5). For the present purpose it is, however, sufficient to divide the first stage of the reaction into ten intervals, each of which corresponds with $\Delta r = 0{\cdot}2$. In this case the end of the first interval coincides with the point of minimum velocity. To illustrate the exact procedure and the nature of the results, the detailed figures are recorded in Table I. The first column gives the initial and final values of r for each interval; the second, the value of $\bar{n} = \bar{r}/r_i$; the third, that of $(\bar{n} + 1/\bar{n})$; the fourth, the initial and final values of q; the fifth, the value of Δq; and the sixth, that of Δt (in mins.).

TABLE I.

Autocatalysis: First Stage.

r'—r''.	$\bar{n}$.	$\bar{n} + 1/\bar{n}$.	q'—q''.	Δq.	Δt.
0·0—0·2	0·5	2·50	0·00—0·24	0·24	180
0·2—0·4	1·5	2·17	0·24—0·56	0·32	276
0·4—0·6	2·5	2·90	0·56—0·96	0·40	258
0·6—0·8	3·5	3·79	0·96—1·44	0·48	237
0·8—1·0	4·5	4·72	1·44—2·00	0·56	222
1·0—1·2	5·5	5·68	2·00—2·64	0·64	211
1·2—1·4	6·5	6·65	2·64—3·36	0·72	202
1·4—1·6	7·5	7·63	3·36—4·16	0·80	196
1·6—1·8	8·5	8·62	4·16—5·04	0·88	191
1·8—2·0	9·5	9·61	5·04—6·00	0·96	187

According to the table, the time required for the completion of the first stage of the reaction is $\Sigma\Delta t = 2160$ minutes. It may further be noted that the value of Δt for equal successive changes in the hydrogen-ion concentration diminishes regularly from the *M.V.* point onwards, *i.e.*, after the first interval. For the ith interval, $\Delta q = 0{\cdot}16 + 0{\cdot}08i$, and since $\bar{n}$ approximates to i as the latter increases, it follows that Δt approaches a limiting value of $1870 \times 0{\cdot}08 = 149{\cdot}6$ minutes.

When the solution of the ester contains a small quantity of

sodium acetate, the hydrogen-ion concentration corresponding with a given concentration of acetic acid (x) is reduced. If the concentration of the acetate (S mols. per litre) is expressed in terms of K, such that $S = mK$, then from $[HA] = x - [H^+] = [H^+](S + [H^+])/K$, we obtain $x = r(r + 1 + m)K$, or $q = r(r + 1 + m)$. Since the end of the first stage is reached when $r = 2$, it follows that the concentration of the acetic acid in the solution at this point increases with the quantity of sodium acetate present. The relation between the velocity of the autocatalysed reaction and the hydrogen-ion concentration is not, however, affected thereby, and the presence of sodium acetate makes no difference to the method described above for the calculation of the time which is occupied by the first stage of the autocatalysis. The values of q and t_1 for the quantities ($m = S/K$) of sodium acetate actually used in the experiments to be described are as follows:

	0	1·2	3·0	6·0
q =	6·0	8·4	12·0	18·0
t_1 =	2160	3215	4800	7450 mins.

Second Stage of the Autocatalysed Reaction.—The beginning of this stage is characterised by the circumstance that the hydroxyl ion ceases to play any sensible part in the hydrolysis. The equation for the reaction velocity may therefore be written

$$dx/dt = k'_h[H^+](a - x) \quad . \quad . \quad . \quad . \quad . \quad (6)$$

As in the case of the first stage, the form of the expression which gives the connexion between x and t is the same whether the hydrolysis takes place in pure water or in a solution which contains a small amount of alkali (sodium acetate). In these circumstances, it seems preferable to consider the general case in which the solution contains S mols. of acetate per litre. Since the hydrogen-ion concentration is given by $[H^+] = \sqrt{(K + S)^2/4 + Kx} - (K + S)/2$, the previous equation may be put in the form

$$dx/dt = k'_h(a - x)(\sqrt{b^2 + Kx} - b) \quad . \quad . \quad (6a)$$

where $b = (K + S)/2$. Replacing $\sqrt{b^2 + Kx}$ by y, equation (6a) may be written

$$k'_h.dt = 2y \,.\, dy/(Ka + b^2 - y^2)(y - b),$$

which, on integration by the method of partial fractions, gives

$$k'_h t = \frac{2b}{Ka}\log(y - b) - \frac{1}{\sqrt{Ka + b^2} - b}\log(\sqrt{Ka + b^2} - y) + \frac{1}{\sqrt{Ka + b^2} + b}\log(\sqrt{Ka + b^2} + y) + \text{const.}$$

Replacing y by its equivalent in terms of x, then for initial and

final values of x and t represented respectively by x', t', and x'', t'', this becomes

$$t'' - t' = \frac{1}{k'_h}\left\{\frac{2b}{\sqrt{Ka}}\log\frac{\sqrt{b^2+Kx''}-b}{\sqrt{b^2+Kx'}-b} + \frac{1}{\sqrt{b^2+Ka}-b}\log\frac{\sqrt{b^2+Ka}-\sqrt{b^2+Kx'}}{\sqrt{b^2+Ka}-\sqrt{b^2+Kx''}} + \frac{1}{\sqrt{b^2+Ka}+b}\log\frac{\sqrt{b^2+Ka}+\sqrt{b^2+Kx''}}{\sqrt{b^2+Ka}+\sqrt{b^2+Kx'}}\right\} \quad . \quad . \quad . \quad . \quad (7)$$

In accordance with this equation, t'' may be used to denote the time required for the reaction to proceed from the end of the first stage ($[H^+] = 2K$) to any point in the second stage. For the later phases of the second stage in the absence of sodium acetate, the above equation reduces to the form

$$t'' - t' = \frac{1}{k'_h\sqrt{Ka}}\left\{\log\frac{\sqrt{a}+\sqrt{x''}}{\sqrt{a}+\sqrt{x'}} - \log\frac{\sqrt{a}-\sqrt{x''}}{\sqrt{a}-\sqrt{x'}}\right\} \quad (8)$$

which is identical with the equation previously derived (Dawson and Lowson, J., 1927, 2107) for the hydrolysis of ethyl acetate with acetic acid (0·1N) as catalyst. Equation (8) follows, in fact, directly from equation (6) when the concentration of the acetic acid is large enough to permit of the substitution of $\sqrt{Kx}$ for $[H^+]$. In these circumstances,

$$v = k'_h\sqrt{Kx}\,(a - x)$$

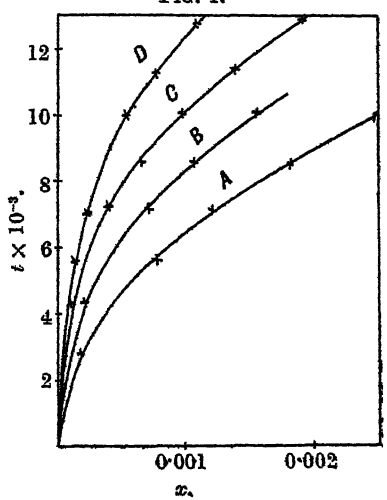
whence $$dv/dx = k'_h\sqrt{K}(a/2\sqrt{x} - 3\sqrt{x}/2) \quad . \quad . \quad . \quad (9)$$

according to which the reaction velocity passes through a maximum when $x = a/3$. Under the conditions of our experiments this maximum is reached before the reverse reaction begins to have any appreciable influence on the course of the hydrolysis.

Experimental.

With one exception the glass vessels used in our earlier experiments were found to retard the autocatalytic hydrolysis as compared with the reaction in silica vessels. In the exceptional case, the results were practically the same as for the silica flasks. Our experience in this connexion would suggest that the determination of the amount of acid produced by autohydrolysis of an ester in a given time might be made the basis of a practical method for the comparison of the "alkalinities" of samples of glass.

Table II gives the results for the early stages of autohydrolysis in silica flasks with and without the addition of alkali. For each experiment the first column of figures shows the number of c.c. of 0·01N-sodium hydroxide required for the titration of 25 c.c. of the ester solution; the second gives the acetic acid concentrations in



mols. per litre, and the third the corresponding time intervals (minutes $\times 10^{-3}$). The calculated times in the fourth column represent the sum of t_1 and t_2, where t_1 is the time occupied by the first stage and t_2 that required by the second stage; these numbers were derived from the theoretical x–t curves.

TABLE II.

3·48	1·39	11·4	10·9
4·80	1·92	12·9	12·6

In comparing the calculated and observed times in the above table it should be recognised that the probable accuracy of the recorded acetic acid concentrations increases as the reaction proceeds, and that the error attaching to the first recorded values may be considerable. It appears that the observed rate of hydrolysis is somewhat more rapid than the theoretical in experiment A, and rather less rapid in B and C, whilst the agreement is very close in experiment D. The fact that the time-differences in A, B, and C are nearly independent of the amount of acetic acid formed suggests that the deviations are associated with the first stage of the autohydrolysis, and it seems probable that they are to be attributed to variations in the purity of the samples of conductivity water used in the several experiments. The experimental x–t curves are shown in Fig. 1.

FIG. 1.

Curves showing the rate of formation of acetic acid by autohydrolysis of ethyl acetate; (A) in pure water; (B), (C), and (D) in presence of 0·000019, 0·000048, and 0·000096 mol. sodium acetate per litre, respectively.

Table III gives the results for an extended autocatalytic experiment in which the hydrolysis was allowed to proceed until the influence of the reverse reaction could no longer be ignored. Col. 1 shows the concentration (x) of the acetic acid formed (mols./litre), col. 2 the corresponding observed time interval (minutes $\times 10^{-3}$), and col. 3 the calculated time $t = t_1 + t_2$ derived by the method already explained.

TABLE III.

$x \cdot 10^2$.	$t \cdot 10^{-3}$, obs.	$t \cdot 10^{-3}$, calc.	$x \cdot 10^2$.	$t \cdot 10^{-3}$, obs.	$t \cdot 10^{-3}$, calc.
0·25	10·0	10·4	8·74	61·8	61·5
0·42	12·8	14·0	10·19	67·5	67·2
1·04	20·0	20·6	12·06	75·1	74·5
1·88	27·2	27·5	13·86	81·9	81·5
2·75	33·0	33·0	16·05	90·6	89·8
3·97	40·2	39·5	17·8	97·6	96·5
5·36	47·4	47·2	19·6	105·0	103·5
6·51	53·1	52·5	21·37	112·5	110·5
7·72	60·7	59·8	22·6	117·9	116·0

The above experiment was continued until about 50% of the original ester had been hydrolysed, at which point the velocity of the reverse reaction is about 1/70th of that of the hydrolytic process. This point may thus be taken to represent approximately the end-point of the reaction in so far as the validity of the equation derived for the second stage in the autohydrolysis is concerned. The tabulated numbers show that the observed progress of the reaction is in close agreement with the combined requirements of equations (5) and (7). It may be inferred that the course of the reaction can be interpreted in terms of the catalytic action of the hydrogen and hydroxyl ions, and that the speed of the uncatalysed reaction and the catalytic activity of the water molecules are too small to be measured.

With reference to the variations in velocity during the autohydrolysis, it may be noted that the maximum velocity given by $v_{max.} = k'_h\sqrt{K}x(a-x)$ with $x = a/3$ is $2{\cdot}64 \times 10^{-6}$ mol. per litre per minute, and the minimum velocity given by $v_{min.} = 2a\sqrt{k'_h k'_{OH} K_w}$ is $1{\cdot}69 \times 10^{-8}$ mol. per litre per minute. The ratio of these velocities is thus proportional to the square root of the ester concentration, and for the concentration used in our experiments is equal to 156.

Summary.

The autocatalysed hydrolysis of ethyl acetate, in so far as this is not appreciably affected by the reverse reaction, has been studied by experiments in fused silica vessels.

The reaction may be divided into two stages, in the first of which the velocity is determined by the joint catalytic action of the

hydrogen and hydroxyl ions, and in the second by the catalytic activity of the hydrogen ion.

Equations are derived from which the time required to reach any given point may be calculated.

The retarding influence of small amounts of alkali is shown to be in accord with theoretical requirements.

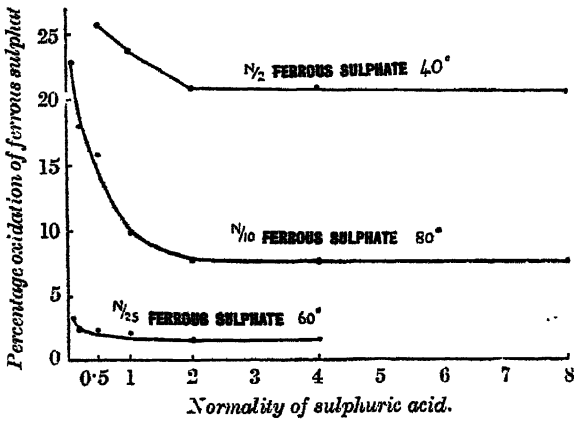
It would seem that the speed of the uncatalysed reaction and the catalytic activity of the water molecules are too small to have any measurable influence on the course of the reaction.

THE UNIVERSITY, LEEDS. [*Received, October 17th*, 1928.]

CCCCXXVIII.—*Stability of Ferrous Sulphate Solutions and their Use in Standardising Permanganate.*

By JOHN ALBERT NEWTON FRIEND and ERIC GEORGE KEMP PRITCHETT.

FOR many years it has been known that dilute, acidified solutions of ferrous sulphate are very resistant at the ordinary temperature to oxidation by free air or oxygen. The first to study the subject systematically appears to have been McBain (*J. Physical Chem.*, 1901, **5**, 623), who introduced oxygenated water into bottles containing solutions of ferrous sulphate in an inert atmosphere. He observed that the reaction was approximately unimolecular, the rate of oxidation being proportional to the oxygen concentration, and rising rapidly both with the temperature and with concentration of the ferrous sulphate solution. He also found that sulphuric acid ranging in concentration from $N/50$ to N (referred to as $N/2$ in the text, but apparently by a typographical error) exerted a small but definite retarding action.



Some of these observations have been confirmed and extended by other investigators (see Peters and Moody, *Amer. J. Sci.*, 1901, **12**, 369; Phelps, *Z. anorg. Chem.*, 1904, **38**, 110; Müller and Kapeller, *Z. Elektrochem.*, 1908, **14**, 76; Baskerville and Stevenson, *J. Amer. Chem. Soc.*, 1911, **33**, 1104), notably by Ennos (*Proc. Camb. Phil. Soc.*, 1913, **17**, 182), who concluded that atmospheric oxidation takes place *via* the un-ionised portion of the ferrous salt, and by Warynski (*Ann. Chim. Analyt.*, 1909, **14**, 45) and Banerjee (*Z. anorg. Chem.*, 1923, **128**, 343), who have studied the retarding or accelerating influence of dissolved salts and free acids, but in very dilute solution only.

On the other hand, Reedy and Machin (*J. Ind. Eng. Chem.*, 1923, **15**, 1271), in contrast to McBain, found that on bubbling air through

solutions of ferrous sulphate ranging in concentration from 2 to 7%, the rate of oxidation was but little affected by the concentration.

Now, Russell (J., 1926, 497) has shown that titanous sulphate in 4*N*-sulphuric acid is very resistant to atmospheric oxidation, and that even vanadous sulphate in 10*N*-sulphuric acid in a burette is not measurably oxidised by air within an hour. It seemed probable, therefore, that comparable concentrations of sulphuric acid might exert a powerful retarding effect upon the oxidation of ferrous sulphate solutions. In view of the wide use of ferrous sulphate for standardising permanganate solutions, it was decided to investigate these points more closely.

FIG. 1.

EXPERIMENTAL.

Influence of Concentration of Sulphuric Acid.—A slow current of purified air, saturated with moisture, was drawn through a series of flasks containing acid solutions of ferrous sulphate kept in a thermostat. At the conclusion of each run, the unoxidised ferrous sulphate was determined by titration with permanganate.* A few typical results are as follows:

Conc. of $FeSO_4$.	Temp.	Period of aspiration (hours).	Percentage oxidation of ferrous sulphate in sulphuric acid of concentration: *N*/10.	*N*/5.	*N*/2.	*N*.	2*N*.	4*N*.	8*N*.
N/25	60°	33	3·22	2·50	2·32	2·11	1·59	1·63	—
N/10	60	33	6·80	5·80	5·19	3·79	2·81	2·79	—
N/10	80	33	22·86	17·97	15·91	9·79	7·94	7·68	7·51
N/2	40	100	—	—	25·72	23·80	20·91	20·88	20·36

These results are shown in Fig. 1. At all the temperatures studied, increase in concentration of sulphuric acid up to 2*N* greatly

* In all experiments a few drops of manganous sulphate solution were added prior to titration.

increased the resistance to oxidation; beyond this point, however, further increase in acid had but little effect. If the function of the sulphuric acid were merely to reduce ionisation of the ferrous salt, one would expect, in accordance with the theory of Ennos, an increased oxidation on addition of the acid.

It would appear, therefore, that some complex is formed in solution which is more resistant to oxidation than un-ionised ferrous sulphate alone.

The increased oxidation with rise of temperature is clearly indicated and is in harmony with previous work.

Influence of Concentration of Ferrous Sulphate.—The foregoing results appear to indicate also that the percentage oxidation rises with the concentration of the ferrous sulphate, as noted by McBain (*loc. cit.*). In view of the contrary statement of Reedy and Machin (*loc. cit.*), however, it seemed desirable to confirm this, since any two of the preceding series may not be strictly comparable owing to the difficulty of ensuring exactly the same conditions of aspiration in two sets of tests. Further experiments were therefore carried out in which air was drawn through flasks containing solutions of ferrous sulphate of various concentrations in *N*-sulphuric acid at 40°. The results were as follows:

Period of aspiration (hours).	Percentage oxidation in ferrous sulphate solution of concentration:			
	N/3.	*N*/5.	*N*/10.	*N*/25.
50	12·03	7·67	3·84	2·24
30	7·14	4·55	2·18	0·44

The percentage oxidation is seen to be approximately proportional to the concentration, the oxidation–concentration curve being only slightly concave to the concentration axis. This supports the view (Ennos, *loc. cit.*) that the reaction is bimolecular at temperatures above atmospheric.

The optimum conditions for stability of ferrous sulphate solutions are thus high dilution, low temperature, and acidity of at least 2*N*.

Preparation of Standard Solutions.—McBain concluded that, since dilute solutions of ferrous sulphate manifest relatively high stability, it should be unnecessary, when preparing standard solutions by dissolving iron in sulphuric acid, to observe the classical precaution of allowing the exit tube from the dissolving-flask to dip into sodium carbonate solution in order to prevent inrush of air during cooling. In two experiments he showed that, upon dissolving 1·4 g. of iron wire in 75 c.c. of 3*N*-sulphuric acid over the Bunsen flame under continuous aëration, finally cooling rapidly and diluting to 250 c.c., the *N*/10-ferrous sulphate solution thus obtained contained only

0·04—0·05% of ferric iron, an amount usually negligible in ordinary volumetric analysis.

In view of the rapid increase in the rate of oxidation with rise of iron concentration, these results can only be taken, without further data, to apply to the particular concentrations used by McBain. The subject does not appear to have been further investigated, and the use of the carbonate trap is still recommended in modern text-books (see Bassett, "The Theory of Quantitative Analysis," 1925, p. 276).

In order to ascertain the limits within which no special precautions to avoid oxidation need be taken, the following experiments were carried out. Weighed pieces of iron wire were put into each of several series of round-bottomed flasks of *ca.* 500 c.c. capacity containing 100—200 c.c. of 4*N*-sulphuric acid, and warmed on the water-bath. The first flask in each series was fitted with a carbonate trap; the others were fitted with vertical tubes through rubber bungs, the tubes being some 20″ in length and of 0·2″ internal diameter. These functioned mainly as air condensers to prevent mechanical loss of solution with the escaping hydrogen, but also assisted to retain an atmosphere of hydrogen within the flask. Immediately the iron had completely dissolved, the flasks were rapidly cooled by immersion in a tank of cold water with gentle agitation but avoiding bubble formation. The contents of each flask were then made up to 250 c.c.,* the suspended carbon allowed to settle—a necessary precaution—and 25 c.c. titrated with permanganate. The results obtained in three selected series are given below, each titration representing the mean of several agreeing to within 0·03 c.c.

Initial vol. of acid.	200 c.c.	200 c.c.	100 c.c.†
Fe (g.) in 250 c.c.‡	4·3	1·4	1·0
Conc. of $KMnO_4$	*N*/3	*N*/10	*N*/10
	C.c. $KMnO_4$ per 0·43 g. Fe.	C.c. $KMnO_4$ per 0·14 g. Fe.	C.c. $KMnO_4$ per 0·1 g. Fe.
With carbonate trap	23·54	25·20	18·10
With vertical tube	23·57	25·22	18·09

† 6*N*-Sulphuric acid.

‡ In all the tests pure Armco iron wire was used. For analysis, see p. 3232.

The results clearly justify the omission of the carbonate trap when a vertical tube is used, provided that (i) the flask is removed from the water-bath immediately the iron has dissolved, and rapidly cooled in cold water, and (ii) the initial concentration of the sulphuric acid is sufficiently high to exceed 2*N* after the iron has dissolved. The former condition entails constant supervision of the experiment, which may be more trouble than the use of the carbonate trap.

* Recently-boiled distilled water was used in the experiment with the carbonate trap and ordinary distilled water in those with the vertical tube.

Experiments were therefore carried out to determine if rigid adherence to that condition is necessary. Approximately 1·4 g. of iron were dissolved in 150 c.c. of 4*N*-sulphuric acid under various conditions, and the solutions made up to 250 c.c. (see footnote, p. 3230); 25 c.c. were titrated with approximately *N*/10-permanganate with the following results (means of two titrations agreeing to 0·02 c.c.), calculated for exactly 1·400 g. of iron.

		$KMnO_4$, c.c.
1.	Carbonate trap	25·69
2.	Vertical tube. Flask removed immediately iron dissolved, and rapidly cooled	25·72
3.	Do. Flask removed immediately iron dissolved, and cooled slowly in air	25·65
4.	Do. Flask kept 20 mins. on water-bath after iron had dissolved; then rapidly cooled	25·71
5.	Do. Flask kept 20 mins. on water-bath after iron had dissolved: cooled slowly in air	25·69
6.	Do. Flask kept 40 mins. on water-bath after iron had dissolved; cooled slowly in air	25·63

These results agree to within 0·4%, which is frequently sufficient for ordinary works practice. The best results are obtained by rapid cooling upon removal from the water-bath, whilst a few minutes extra on the bath after the iron has dissolved do not appreciably influence the result (Expts. 2 and 4).

In almost every case the vertical-tube method, as carried out in Expt. 2, yielded a slightly higher result (*ca.* 0·1%) than the carbonate-trap method. This would have been attributed to experimental error had it not occurred so persistently. Possibly it was due to traces of dissolved oxygen in the carbonate trap for, as shown below, the results obtained by the vertical-tube method are probably most correct, since they agree very closely with those obtained with sodium oxalate. Experiments with appreciably higher concentrations of ferrous sulphate, *viz.*, *N*/5 upwards, diverged appreciably from the standard under conditions 3, 5, and 6 above. This was to be expected in view of the increased rate of oxidation with rise in concentration. As such concentrations are less frequently used in practice the subject was not pursued further, but the results on p. 3230 show that excellent results are obtainable with even *N*/3 solutions by use of the vertical-tube method, provided that the precautions mentioned are duly observed.

The vertical-tube method of preparing *N*/10-ferrous sulphate solution has been found very useful in our laboratory. It is often more convenient than others because variations in temperature and acidity at the moment of titration do not affect the accuracy (Kolthoff, *Pharm. Weekblad*, 1924, **61**, 1082), whereas ferrous ammonium sulphate crystals vary slightly in composition (Hackl, *Chem. Ztg.*, 1922, **46**, 1065), and the temperature of sodium oxalate requires

regulating (Schröder, *Z. öffentl. Chem.*, 1910, **16**, 270, 290; Kolthoff, *loc. cit.*, p. 561). The last two methods, however, may be made to yield very accurate results agreeing to about 0·05% (McBride, *J. Amer. Chem. Soc.*, 1912, **34**, 393; Kolthoff, *Z. anal. Chem.*, 1924, **64**, 255; Hendel, *ibid.*, 1923, **63**, 321) if suitable precautions are taken. It was thus desirable to ascertain if these methods yielded results identical with the present one, as this does not appear to have been determined hitherto with accuracy. One difficulty is that for accurate work it is, of course, necessary to determine with proportionate exactness the composition of the iron used. This may be less convenient than the preparation of pure oxalates or ferrous salts. Electrolytic iron is frequently recommended, although even such metal is liable to contain appreciable amounts of impurity. A few parallel experiments have been carried out with sodium oxalate and Armco iron wire, the composition of which was as follows: C, 0·025; Si, 0·009; S, 0·033; P, 0·009; Mn, 0·036; Cu, 0·036; Fe (by difference) 99·852%. *N*/10-Solutions of permanganate, sodium oxalate, and ferrous sulphate were prepared, the last-named by dissolving 1·4 g. of iron wire in 200 c.c. of 4*N*-sulphuric acid on the water-bath, using the vertical tube, rapidly cooling in a tank of cold water and making up to 250 c.c. The permanganate was then standardised by titration with each of the above solutions. In titrating the sodium oxalate, the precautions mentioned by Schröder (*loc. cit.*) were carefully observed.

The following factors for two approximately *N*/10-permanganate solutions were obtained in two sets of experiments: with oxalate, (1) 0·9915, (2) 0·9878; with iron, (1) 0·9916, (2) 0·9866. Provided, therefore, that the composition of the iron is accurately known, this method of standardising permanganate agrees to within about 0·1% with that by sodium oxalate for *N*/10-solutions.

Conclusion.

In preparing standard solutions of ferrous sulphate by dissolving iron in sulphuric acid, a carbonate trap is not necessary. Very accurate results are obtainable when 150—200 c.c. of 4*N*-sulphuric acid and up to 1·4 g. of iron are warmed in a flask, fitted with a vertical tube, on the water-bath, and, immediately the iron has dissolved, rapidly cooled in water, and made up to a minimum of 250 c.c. Provided that the composition of the iron is accurately known, the result of standardising permanganate with such a solution agrees to within 0·1% with the sodium oxalate method.

THE TECHNICAL COLLEGE, BIRMINGHAM. [*Received, October 18th*, 1928.]

CCCCXXIX.—*Note on the Rate of Photochemical Combination of Chlorine and Hydrogen in Glass Capillary Tubes.*

By David Leonard Chapman and Philip Powell Grigg.

Determinations were recently made by Briers and Chapman (this vol., p. 1802) of the rates of photochemical union of bromine and hydrogen when the illumination of the mixture was intermittent, and it was shown that the results obtained could be interpreted by the assumption that the union of the gases is due to a catalyst formed by the light, and having an average life of an appreciable fraction of a second. As the results of the measurements of the rates of chemical change can in general be explained by more than one set of hypotheses, it is desirable that evidence, if possible of a different character, should be obtained of such long-lived catalysts in other cases of photochemical change. The experimental method adopted in the case of bromine and hydrogen cannot be applied, as already explained (*loc. cit.*), in the case of chlorine and hydrogen. However, there is another simple method of testing whether a similar theory is applicable to the photochemical union of the latter gases.

If we postulate that the union of chlorine and hydrogen is due to an unstable catalyst, and that the catalyst is destroyed when it comes into contact with glass or a film of water, then obviously if the catalyst has an appreciable life it ought to be possible to show that in light of the same intensity the rate of union of chlorine and hydrogen in capillary tubes is less than in tubes of wider diameter. The experiment has been performed and has furnished a positive result.

The determinations were made with a hermetically sealed glass apparatus of the form of a U-tube of which one limb was a capillary tube of 1 mm. internal diameter, and the other limb a tube of about 2·5 cm. diameter. The apparatus contained about 3 c.c. of water and electrolytic gas at atmospheric pressure. In purifying the water and in preparing the electrolytic gas, the usual precautions were taken to eliminate destructible inhibitors. Furthermore, as an additional precaution, the apparatus, after it had been filled and sealed, was heated at 130° for 6 hours in a bath of glycerol.

The preliminary experiments were performed in the following manner. The previously filled apparatus was placed in a horizontal position and the water removed from the capillary tube by heating it with steam. Then, in order to be certain that the capillary tube contained gas of the same composition as that in rest of the apparatus, the former was warmed and cooled many times. The apparatus was

next fixed in a vertical position so that the water enclosed the gas in the capillary tube, which was then warmed so as to drive out about one-fourth of the gas it contained. The water which moved up the capillary tube on its regaining the temperature of the laboratory served as an index.

When the whole apparatus was exposed to light, so that both tubes were equally illuminated, the index in the capillary tube moved downwards, showing that the rate of combination of the gases in the wider tube was more rapid than that of the gases enclosed in the capillary. After exposure to light and before the final reading of the index was taken, the apparatus was allowed to stand at a constant temperature in the dark for 12 hours to ensure the attainment of complete equilibrium. Then, in order to estimate the proportions of hydrogen chloride formed in the wide and narrow tubes, the apparatus was completely immersed in water in an upright position, and the sealed end of the wide tube opened. The water which immediately entered the wider tube filled from one-third to one-half of its volume, showing that a considerable proportion of the gases originally contained therein had combined. The index in the capillary tube, however, only rose to its initial position, thereby showing—since the pressure of the gas in the capillary tube was initially and finally approximately the same, namely, that of the atmosphere—that only a small proportion of the gases introduced into it had united.

To measure more accurately the relative rates of combination in the two tubes, the capillary tube alone and the wider tube alone were alternately exposed to light of the same intensity. The downward movement of the index which accompanied the exposure of the wider tube to light was 40—60 times more rapid than the upward movement of the index resulting from the illumination of the capillary tube alone. Before the readings were taken, sufficient time was always allowed to elapse to ensure complete solution of the hydrogen chloride formed, and a correction was applied for the light totally reflected from the sides of the bore of the capillary tube. That the ratios of the rates of combination observed in different experiments were not constant was to be expected, since electrolytic gas contains varying small proportions of oxygen, which, being an inhibitor, would shorten the life of the catalyst.

The precautions taken to destroy destructible inhibitors appear to us to exclude the possibility that the observed effect was due to the gradual escape of such inhibitors from the surface of the glass. Moreover, the possibility that the rate of union of the chlorine and hydrogen in the capillary tube was inhibited by hydrochloric acid is excluded by well-known experiments of Bodenstein.

From the above-described phenomenon, an attempt will be made, with an apparatus designed for the purpose, to obtain an estimate of the life of the catalyst.

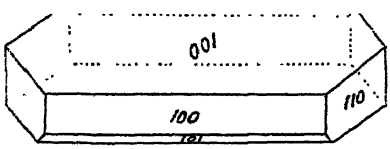
JESUS COLLEGE, OXFORD. [*Received, October 23rd,* 1928.]

CCCCXXX.—*Crystallography of the Aliphatic Dicarboxylic Acids.*

By WILLIAM AUGUSTUS CASPARI.

THE straight-chain saturated acids of this series, besides being all solid at the ordinary temperature, lend themselves better to crystallographic study than the corresponding monocarboxylic acids, in that their crystals are harder and less liable to distortion. An advantage, moreover, of dealing with acids of comparatively low molecular weight is that crystals can be procured which have a reasonable thickness in the direction of the *c* axis instead of being excessively thin and tabular.

Angle measurements on crystals of the lower members of the series, up to pimelic acid (C_7) have been made by various workers. From C_4 onwards they all crystallise in the monoclinic–prismatic class. The results of an *X*-ray examination of succinic acid (C_4) have been published by Yardley (*Proc. Roy. Soc.*, 1924, *A*, **105**, 451). A number of data bearing on the spacings of the basal planes, obtained by *X*-ray powder photographs and carried up to C_{34}, are due to Normand, Ross, and Henderson (J., 1926, 2632; *Proc. Roy. Soc. Edin.*, 1928, **48**, 20). It is assumed by the latter workers, and is now amply confirmed, that the length of the unit cells of these crystals, along *c*, depends on the number of carbon atoms in the molecule, as established by Shearer and Müller for other long-chain compounds.



The acids available in the form of single crystals for the present examination were adipic (C_6), pimelic (C_7), suberic (C_8), azelaic (C_9), sebacic (C_{10}), brassylic (C_{13}), and hexadecanedicarboxylic (C_{18}). For obtaining crystals of adequate quality, ethyl acetate was found in most cases to be the best solvent. With all the acids, cooling of hot aqueous solutions leads to crystals which are well-shaped except for extreme thinness upon (001), whereby they are rendered useless; but pimelic acid crystallises best by isothermal evaporation from water, in which it is moderately easily soluble in the cold. For sebacic acid, cooling of warm solutions in concentrated nitric acid gave the best results. Good crystals of sebacic acid were not obtained until the method was adopted of heating

the substance with ether in sealed tubes to about 100° and allowing it to cool in the oven.

Externally, the crystals of all the acids conform to the same type, with variations in face-development due to impurities and to the kind of solvent employed. The principal forms are always (001), (100), and (110), with, occasionally, (10$\bar{1}$) and (010). On pimelic acid crystals, (011) was also observed. Throughout the series, (001), (100), and (110) are pronounced cleavage-planes. The crystals are tabular upon (001) and become progressively thinner as the molecular weight rises. The majority of them are elongated along the *b* axis, so that on the whole the characteristic habit is that shown in Fig. 1. The β-angle is unusually large, varying from 128° to 137°. Swallow-tail twins about (001), with the *b* axes aligned, are common, and crossed twins about (001), with the *b* axes at right angles, also occur.

In the lower members of the series (10$\bar{1}$) is almost as well developed as (100), and earlier observers have sometimes chosen the former as containing the *c* axis, thus reducing β to the neighbourhood of 90°. As one ascends the series, however, the crystals seldom or never display the nearly orthogonal (10$\bar{1}$) face, whilst the highly tilted (100) face is always in evidence, besides being a definite cleavage-plane. The large β-angle therefore appears to be a reality. Angles lying in the same region of magnitude have been observed by Müller (*Proc. Roy. Soc.*, 1927, *A*, **114**, 542) in bromostearic, stearolic, and behenolic acids.

FIG. 1.

The β-angle of adipic acid (Brugnatelli, *Z. Kryst.*, 1896, **26**, 298) is known from earlier measurements. Those of the other acids concerned were now determined goniometrically. Whereas reflexions from (001) were uniformly good, those from (100) were less satisfactory, owing to the narrowness of the face and its tendency to unevenness. It was therefore considered advisable to select the results of the best reflexions from several crystals and to state the mean to the nearest 10′. The angles so found agree, within the experimental limits, with those which may be independently calculated from the *X*-ray spacings of the (001) and (100) planes.

The crystals were subjected to *X*-ray analysis by means of rotation photographs of single crystals about their three axes, upon glass quarter-plates. When required for closer investigation of particular reflexions, oscillation photographs were also taken. The

β-angles and cell-dimensions (in Å.U.) of the several crystals are summarised in Table I.

TABLE I.

Acid.	*a*.	*b*.	*c*.	β.	Mols. in cell.
C_6, Adipic	10·27	5·16	10·02	137° 5′	2
C_7, Pimelic	9·93	4·82	22·12	130° 40′	4
C_8, Suberic	10·12	5·06	12·58	135° 0′	2
C_9, Azelaic	9·72	4·83	27·14	129° 30′	4
C_{10}, Sebacic	10·05	4·96	15·02	133° 50′	2
C_{12}, Brassylic	9·63	4·82	37·95	128° 20′	4
C_{18}, Hexadecanedicarboxylic	9·76	4·92	25·10	131° 10′	2

The first point of interest which is brought out by these figures is that the unit cells of all the acids have about the same breadth and depth. From this alone it necessarily follows that the carbon-atom chain of the structural molecule must be strung out along the *c* axis.

As regards the *c* dimensions of the several unit cells, it is seen that the crystals fall into two groups, according to the odd or even number of carbon atoms in the molecule. The *c* axes of the even-carbon series are nearly proportional to the number of carbon atoms, whilst in the odd-carbon series they are proportional to twice that number. In the latter series the heights of the cells are doubled and must be taken up by two molecules end to end; correspondingly the cells contain the substance of four instead of two molecules.

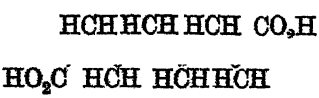
This difference in crystal structure between even-carbon and odd-carbon acids cannot be unconnected with the well-known alternation in their melting points. Ultimately the melting point must depend on the ease with which molecules are torn out of the crystal lattice, and it is plausible to suppose that the double cells of the odd-carbon acids (having relatively lower m. p.'s) are less stable in this respect than the more compact cells of the even-carbon acids. A full explanation, however, must be deferred until not only the exact structures of the crystals but also the degree of molecular association in the molten substances are better known.

An alternation in most of the data in Table I is apparent as the homologous series is ascended, and is especially striking with the β-angles, which are always considerably smaller for odd-carbon than for even-carbon acids. The gentle alternation in the *a* and *b* cell-dimensions shows a tendency to die out as the molecular weight rises.

With each crystal, reflexions from planes to the number of 30—50 were identified upon the photographs. Owing to the close similarity of all the *a* and *b* axial lengths, the rotation photographs about these respective axes were much alike among themselves, whilst the *c* axis photographs varied characteristically with the crystal. Reflexions from (110) and (200) were very strong through-

out, and (211) fairly strong. In the even-carbon series, (210), which did not appear at all in the odd-carbon series, was also fairly strong. On the other hand, (011) appeared intensely in the latter but only faintly or not at all in the former series; this confirms the structures in Fig. 2, where (011) planes in the odd-carbon series are seen to have a greater reticular density than (011) planes in the even-carbon series.

Orders of (001) attained at most only moderate intensity and were represented by both odd and even orders, beginning with (001), in the even-carbon acids, but by even orders only, beginning with (002), in the odd-carbon acids. By a simple application of the structure factor of intensity, this disappearance of the odd orders indicates a division of the unit cell across c into halves of nearly equivalent reflecting power, and is what would be expected from the structure (Fig. 2) of odd-carbon acids. A minor subdivision of the c heights is caused by successive layers of the carbon atoms themselves in the plane of (001). The effect of this, again by operation of the structure factor, is well brought out in the c axis photographs, where remote hyperbolas (layer-lines) show a certain intensity after an interval of weak or unrepresented hyperbolas. Thus, in adipic acid the 3rd and 4th hyperbolas are relatively strong, in suberic the 4th and 5th, in sebacic the 6th, and in the C_{18} acid the 8th and 9th. In pimelic acid the 8th hyperbola emerges strongly, in azelaic the 10th, and in brassylic the 14th.



On scrutinising all the planes represented by X-ray reflexions, it was found that in no case is there a general halving in the (hkl) series; hence the space-lattice is the simple lattice Γ_m. On the other hand, such planes as (100), (101), (300), etc., did not appear, but (200), (205), (402), etc., were frequent; that is, $(h0l)$ is halved when h is odd. Lastly, since (020) appears but never (010), we may conclude that the space-group is C_{2h}^5.

If the molecule is asymmetrical, four differently oriented molecules must constitute a unit cell. Such is the case with odd-carbon acids; their molecules therefore must be without symmetry. In the case of even-carbon acids there are only two in the cell, and the molecule must have a centre of symmetry of its own which it contributes to the symmetry of the cell. From the structural formulæ, it is easily seen how the one series of acids can have central symmetry and the other none, thus :

Odd :—

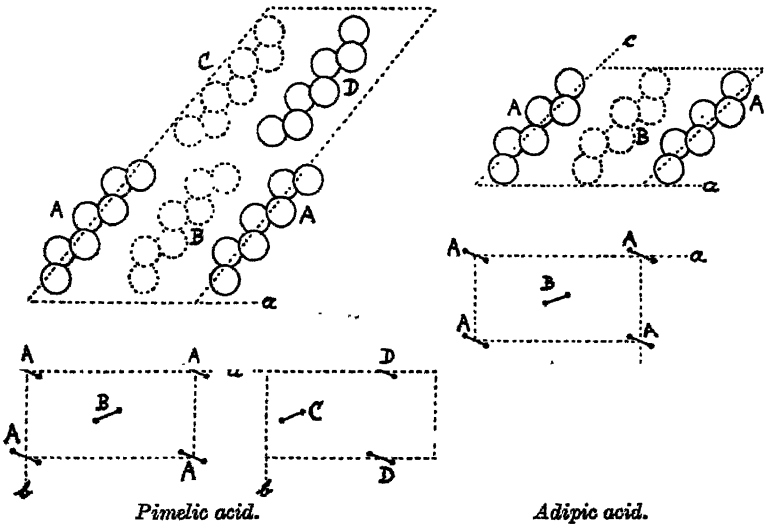
Even :—

Any straight line drawn through the centre of symmetry at × cuts equivalent atoms or groupings at opposite boundaries of the molecule when the carbon-atom number is even, but not when it is odd. Similar considerations apply, for example, to hydrocarbons; and, indeed, it is found by Müller (*loc. cit.*) that octadecane, $C_{18}H_{38}$, has two molecules to the cell, but $C_{29}H_{60}$ has four. All monocarboxylic acid molecules may be expected to be asymmetrical and to form four-molecule cells.

Some further points of similarity and contrast between the several acids may be gathered from Table II.

TABLE II.

Acid.		*d*.	*ab* sin β.	*D*.	Gap.
C_6,	Adipic	1·340	36·18	—	3·70
C_7,	Pimelic	1·313	36·26	—	3·47
C_8,	Suberic	1·270	36·24	2·56	3·73
C_9,	Azelaic	1·252	36·22	2·50	3·47
C_{10},	Sebacic	1·240	35·96	2·48	3·65
C_{13},	Brassylic	1·173	36·41	2·50	3·81
C_{18},	Hexadecanedicarboxylic ...	1·138	36·20	2·64	3·62
	Mean		36·21	2·53	3·63



The densities are calculated by the relation $d = 1{\cdot}66MN/abc \sin \beta$, where M is the molecular weight and N the number of molecules in the unit cell. Values so found contain the errors of four separate experimental quantities, and are not precise enough to decide whether there is an alternation along the series; if there is, however, it can be but slight.

The quantity $ab \sin \beta \times 10^{-16}$ cm.^{2} expresses the area of a section of the unit cell taken, not along (001), but at right angles to the *c* axis, and is seen to be fairly constant. Moreover, all the long-chain aliphatic compounds hitherto examined, including bromostearic acid, show similar values for $ab \sin \beta$, ranging from 35·8 to $37{\cdot}8 \times 10^{-16}$ cm.^{2}. This remarkable uniformity leaves it hardly doubtful that all the crystals concerned are built up in the same way, *viz.*, of parallel bundles of carbon-atom chains along the *c* axis, with ample space between them to accommodate hydrogen, oxygen, and other atoms.

The lengths of the *c* axes in Table I would not permit a row of carbon atoms of diameter 1·54 Å.U. to lie with their centres in a straight line; these atoms must therefore lie in zigzag formation along the chain. The unit cells of adipic and pimelic acids, on this hypothesis, are shown diagrammatically in Fig. 2, with the (010) face or monoclinic plane of symmetry in the plane of the paper. The ground-plans of the corresponding (001) or basal sides of the cell are given underneath. The molecules are shown as flat zigzag

chains of carbon atoms, the angle of zigzag being not far from the tetrahedral angle. There is as yet no evidence as to the arrangement of the methylenic hydrogen atoms or of the groups of hydrogen and oxygen atoms which cluster at each extremity, and they are not shown in the figure; in the case of even-carbon acids, however, we know that all these atoms must be disposed in harmony with the centro-symmetry of the molecule.

Those molecules which lie half-way across the cell are drawn in dotted lines. Molecules B, in the case of even-carbon acids, are so disposed as to lie symmetrically both across a glide-plane and about

Pimelic acid. *Adipic acid.*

a screw-axis towards molecules A. In the odd-carbon cell, molecules B are reflexions of A, molecules C are derived by rotation from A, and molecules D are reflexions of C. The upper half of the cell is provisionally shown slightly displaced against the lower half in the a direction, on the analogy of the structure of $C_{29}H_{60}$ as worked out by Müller (*Proc. Roy. Soc.*, 1928 *A*, **120**, 437), but space-group considerations alone afford no information as to this. The planes of the zigzag chains will not lie exactly parallel to (010) or (100), because the central molecule B would then be almost identical with A, in which case we should expect halvings of the (*hkl*) planes in the *X*-ray spectra. In Fig. 2 the projections of the molecules upon the base are shown inclined at an undetermined angle, which angle, or its symmetrical counterpart, must be the same for all molecules.

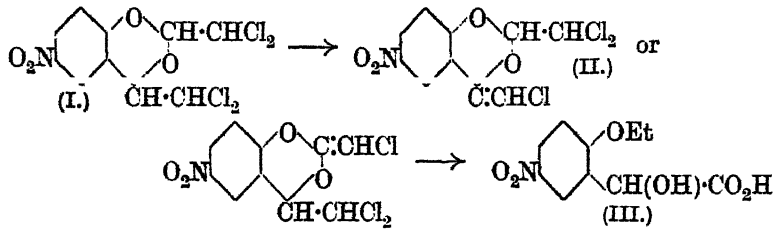
The available data enable us to calculate the distance (D) between

successive carbon atoms on any one side of the chain—the wavelength, as it were, of the zigzag. By subtracting 2*c* of each even-carbon acid from 2*c* of adipic acid, and *c* of odd-carbon acids from *c* of pimelic acid, and dividing by the difference in the number of carbon atoms in the molecules, we obtain the required distances, which are stated in col. 3 of Table II. Although the results are only roughly constant, they point to a uniform mean distance, between centres of carbon atoms, of 2·53 Å.U. Here again there is striking agreement with other crystal structures. For diamond, the corresponding distance is 2·52 Å.U., whilst for the hydrocarbon $C_{29}H_{60}$ it has been evaluated (Müller, *loc. cit.*, 1928) as 2·537 Å.U.

Lastly, it is clear that in each crystal there must be a gap between successive molecules, measured in the line of the *c* axis, since the quotient c/n decreases as the molecules grow longer. This gap, as between centres of terminal carbon atoms, is found by calculating $c - 2{\cdot}53(n - 1)/2$ or $c/2 - 2{\cdot}53(n - 1)/2$, and the results are given in the fourth column. If the diameter of the carbon atom be assumed to be 1·54 Å.U., the mean gap of 3·63 Å.U. between centres corresponds to a clear gap of 2·09 Å.U., to the filling of which the oxygen and hydrogen atoms of two carboxyl groups must contribute. The extent of the gap is somewhat larger than that found for $C_{29}H_{60}$, *viz.*, 3·09 Å.U. between centres, as might be expected when the molecule has carboxyl groups at each end.

The author desires to express his indebtedness to Prof. J. F. Thorpe, F.R.S., and to Mr. N. K. Adam for courteous gifts of specimens, and to Sir William Bragg, F.R.S., for the interest he has taken in this work.

DAVY FARADAY LABORATORY,
THE ROYAL INSTITUTION. [*Received, October 24th*, 1928.]

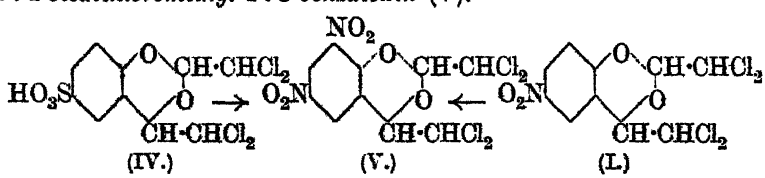


CCCCXXXI.—*The Condensation of Dichloroacetaldehyde with Phenols.*

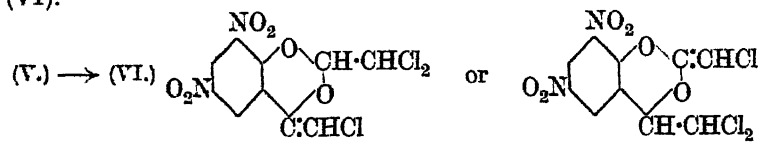
By FREDERICK DANIEL CHATTAWAY and ALEXANDER ALLAN MORRIS.

THE new type of condensation between phenols and aldehydes leading to the formation of the dioxin ring (J., 1926, 2720; 1927, 685, 2013; this vol., p. 1088) is not confined to chloral, but appears to be a general reaction of those aldehydes which can be kept in contact with concentrated sulphuric acid for some time without decomposition. Dichloroacetaldehyde, for example, reacts with *p*-nitrophenol and phenol-*p*-sulphonic acid even more readily than chloral itself.

Thus with *p*-nitrophenol two molecules of the aldehyde condense with loss of one molecule of water, the final product being 6-*nitro*-2 : 4-*bisdichloromethyl*-1 : 3-*benzdioxin* (I). No hydroxyl group is present in the molecule, since the compound does not dissolve in dilute alkali solution and can be recrystallised unchanged from boiling acetic anhydride. It contains the nitro-group unchanged, since this can be reduced to an amino-group which can be acetylated or diazotised and replaced, the dioxin ring remaining unbroken during these reactions.



When the benzdioxin (I) is acted upon by alcoholic potash at 50—60°, one molecule of hydrogen chloride is removed from one of the ·CH·CHCl$_2$ groups with formation of 6-*nitro*-2(or 4)-*dichloromethyl*-4(or 2)-*chloromethylene*-1 : 3-*benzdioxin* (II). If the temperature is not controlled, reaction proceeds further with the formation of 5-nitro-2-ethoxymandelic acid (III) as the final product, a reaction which establishes the constitution of the compound.



Similarly, dichloroacetaldehyde condenses with phenol-*p*-sulphonic acid, yielding 2 : 4-*bisdichloromethyl*-1 : 3-*benzdioxin*-6-*sulphonic acid* (IV). This compound behaves as a normal sulphonic acid. It is a colourless solid with no definite melting point and crystallises with one molecule of water. This molecule of water is probably attached to the sulphonic residue, since the ammonium salt is obtained in the anhydrous condition.

When acted upon by phosphorus pentachloride, the sulphonic acid yields a *sulphonyl chloride*. This with methyl and ethyl alcohols yields *esters*, with ammonia a *sulphonamide*, and with aniline a *sulphonanilide*.

The constitution of the sulphonic acid is similar to that of the condensation product (I), yielded by *p*-nitrophenol and dichloroacetaldehyde, since both compounds on nitration yield 6 : 8-*dinitro*-2 : 4-*bisdichloromethyl*-1 : 3-*benzdioxin* (V).

When acted upon by alcoholic potash, the dinitro-compound (V) loses one molecule of hydrogen chloride with formation of 6 : 8-*dinitro*-2(or 4)-*dichloromethyl*-4(or 2)-*chloromethylene*-1 : 3-*benzdioxin* (VI).

The further action of alcoholic potash causes profound decomposition.

EXPERIMENTAL.

6-*Nitro*-2 : 4-*bisdichloromethyl*-1 : 3-*benzdioxin* (I).—Dichloroacetaldehyde alcoholate (70 g.; 2 mols.) was added slowly with shaking to a well-cooled solution of *p*-nitrophenol (30 g.; 1 mol.) in 300 c.c. of concentrated sulphuric acid. The solution became warm and fumes of hydrogen chloride were given off while a viscid, yellow solid slowly separated on the surface. The mixture was kept at the ordinary temperature for 4 hours with occasional shaking and then poured over crushed ice. The viscid, brown solid obtained was freed from sulphuric acid by repeated washing with hot water and dissolved in boiling alcohol, in which it was readily soluble. On cooling, 6-*nitro*-2 : 4-*bisdichloromethyl*-1 : 3-*benzdioxin* separated. It was freed from a little unchanged *p*-nitrophenol by washing with warm dilute ammonia and hot water and recrystallised several times from boiling alcohol, in which it was very soluble, separating in pale yellow, flattened, rhombohedral plates (23 g.), m. p. 113·5° (Found : C, 35·0; H, 2·1; N, 4·1; Cl, 41·2; *M*, cryoscopic in benzene, 352, 357. $C_{10}H_7O_4NCl_4$ requires C, 34·6; H, 2·0; N, 4·0; Cl, 40·9%; *M*, 347).

6-*Nitro*-2(or 4)-*dichloromethyl*-4(or 2)-*chloromethylene*-1 : 3-*benzdioxin* (II).—6-Nitro-2 : 4-bisdichloromethyl-1 : 3-benzdioxin (20 g.; 1 mol.) was gradually added to a solution of potassium hydroxide (24 g.; 7 mols.) in 250 c.c. of alcohol kept at 50—60° by frequent cooling. The dark brown solution was then nearly neutralised with hydrochloric acid, the alcohol distilled off in steam, and the viscid, brown residue crystallised several times from alcohol and finally from chloroform–light petroleum. The 6-*nitro*-2(or 4)-*dichloromethyl*-4(or 2)-*chloromethylene*-1 : 3-*benzdioxin* thus obtained separated from boiling alcohol, in which it was easily soluble, in slender, very pale yellow prisms, m. p. 108° (Found : C, 38·[illegible]; H, 2·0; N, 4·7; Cl, 34·2. $C_{10}H_6O_4NCl_3$ requires C, 38·6; H, [illegible]; N, 4·5; Cl, 34·3%). Although apparently unsaturated, the compound does not form an addition product with bromine.

5-Nitro-2-ethoxymandelic Acid (III).—A vigorous reaction took place when 25 g. (1 mol.) of the nitro-compound (I) were added gradually to a hot solution of 30 g. (7 mols.) of potassium hydroxide in 250 c.c. of alcohol, the temperature rising and the solution darkening. The solution was gently boiled for 15 minutes and then nearly neutralised with hydrochloric acid and the alcohol was distilled off in steam. From the filtered solution, strongly acidified with hydrochloric acid, ether extracted 5-nitro-2-ethoxymandelic acid (5 g.), m. p. 138° after crystallising from hot water (compare Chattaway, J., 1926, 2724) (Found: C, 49·7; H, 4·65; N, 5·8. Calc. for $C_{10}H_{11}O_6N$: C, 49·8; H, 4·6; N, 5·8%). The acetyl derivative formed rhombic plates, m. p. 147° (compare Chattaway, *loc. cit.*).

6-Amino-2:4-bisdichloromethyl-1:3-benzdioxin.—Iron filings (15 g.; 3 mols.) were added in small quantities to a hot solution of 30 g. (1 mol.) of the nitro-compound (I) in 250 c.c. of alcohol containing 66 c.c. (7 mols.) of 33% hydrochloric acid. The hot green solution was filtered, the alcohol removed partly by distillation and finally by evaporation on the water-bath, 100 c.c. of cold water were added to the solid residue to dissolve the iron salts, and on filtration the *hydrochloride* of 6-amino-2:4-bisdichloromethyl-1:3-benzdioxin was left as a crystalline mass of small, colourless prisms (30 g.). After recrystallisation from boiling dilute hydrochloric acid, in which it was easily soluble, it melted and decomposed at about 210° (Found: Cl, 50·1. $C_{10}H_9O_2NCl_4,HCl$ requires Cl, 50·2%).

On warming the hydrochloride with a dilute solution of sodium carbonate, *6-amino-2:4-bisdichloromethyl-1:3-benzdioxin* was liberated as a colourless solid, readily soluble in boiling dilute alcohol, from which it separated in thin, colourless, lustrous plates, m. p. 108·5—109·5° (Found: Cl, 44·8. $C_{10}H_9O_2NCl_4$ requires Cl, 44·75%).

6-Acetamido-2:4-bisdichloromethyl-1:3-benzdioxin was formed with evolution of heat when the base was heated for a few minutes with acetic anhydride (slightly more than 1 equiv.), and the *6-diacetamido*-derivative was formed when the base (2 g.) was boiled for 5 minutes with acetic anhydride (10 c.c.) and one drop of concentrated sulphuric acid. They separated from boiling dilute alcohol, the former in small compact prisms, m. p. 149—150° (Found: Cl, 39·5. $C_{12}H_{11}O_3NCl_4$ requires Cl, 39·5%), and the latter in small plates, m. p. 145° (Found: Cl, 35·35. $C_{14}H_{13}O_4NCl_4$ requires Cl, 35·4%).

A solution of 2:4-bisdichloromethyl-1:3-benzdioxin-6-diazonium chloride was formed when nitrous fumes were passed into a solution of 15 g. of the preceding hydrochloride in 50 c.c. of alcohol, through which a little dry hydrogen chloride had been passed, cooled to −6°. On addition of bromine dissolved in a saturated solution of potassium

bromide, 2 : 4-*bisdichloromethyl*-1 : 3-*benzdioxin*-6-*diazonium perbromide* separated as a canary-yellow solid. The perbromide is remarkably stable and crystallises unchanged from warm acetic acid, containing a little free bromine, in small, compact, orange prisms which decompose with brisk evolution of bromine at 128—129° (Found: Cl + Br, 67·1. $C_{10}H_7O_2N_2Cl_4Br_3$ requires Cl + Br, 67·1%).

When boiled for some time with acetic acid, the perbromide decomposes with evolution of bromine, and from the concentrated cooled solution, 6-*bromo*-2 : 4-*bisdichloromethyl*-1 : 3-*benzdioxin* separates in small, colourless, lustrous plates, m. p. 91·5° (Found: Cl + Br, 58·1. $C_{10}H_7O_2Cl_4Br$ requires Cl + Br, 58·2%).

2 : 4-*Bisdichloromethyl*-1 : 3-*benzdioxin*-6-*sulphonic Acid* (IV).—To a well-cooled solution of 30 g. of phenol (1 mol.) in 300 c.c. of concentrated sulphuric acid, 102 g. of dichloroacetaldehyde alcoholate (2 mols.) were added slowly with stirring. After remaining at the ordinary temperature for 6 hours with occasional stirring, the mixture was poured over 150 g. of ice. The *sulphonic acid*, which separated as a white solid, was recrystallised from hot, dilute hydrochloric acid (yield, 40 g.), dried on the water-bath, and dissolved in boiling chloroform, in which it was only very moderately soluble; on addition of low-boiling petroleum it separated in minute, colourless prisms containing $1H_2O$, m. p. 150—155° (decomp.) (Found: C, 30·0; H, 2·5; S, 8·2; Cl, 35·6. $C_{10}H_8O_5Cl_4S,H_2O$ requires C, 30·0; H, 2·5; S, 8·0; Cl, 35·5%).

The monohydrated acid is very soluble in water, acetic acid, alcohol, and ether, and very sparingly soluble in benzene. When heated at 105—110°, it slowly decomposes. It forms an anhydrous *ammonium* salt, which separates from a dilute solution of ammonia in extremely small, colourless prisms (Found: N, 3·5; S, 8·4; Cl, 35·6. $C_{10}H_{11}O_5NCl_4S$ requires N, 3·5; S, 8·05; Cl, 35·55%).

6 : 8-*Dinitro*-2 : 4-*bisdichloromethyl*-1 : 3-*benzdioxin* (V).—To 20 g. of the monohydrated acid suspended in 40 c.c. of concentrated sulphuric acid, a mixture of 40 c.c. of nitric acid (*d* 1·5) and 40 c.c. of nitric acid (*d* 1·41) was added slowly with shaking. Heat was evolved and an emulsion of oily drops was formed. After vigorous shaking for 10 minutes the emulsion was poured into a mixture of ice and water; a semi-solid mass then separated which solidified on cooling. This was crushed and washed with warm water, dried on the water-bath, and dissolved in alcohol, in which it was easily soluble and from which it separated in small, compact, slightly yellow prisms, m. p. 133·5—134·5° (Found: N, 7·1; Cl, 36·2. $C_{10}H_6O_6N_2Cl_4$ requires N, 7·15; Cl, 36·2%).

6 : 8-*Dinitro*-2 : 4-*bisdichloromethyl*-1 : 3-*benzdioxin* identical with

the above compound in every way was obtained when 6-nitro-2 : 4-bisdichloromethyl-1 : 3-benzdioxin (I) was nitrated in the same manner. Unlike the analogously constituted 6 : 8-dinitro-2 : 4-bistrichloromethyl-1 : 3-benzdioxin (compare Chattaway and Morris, J., 1927, 2013), it does not form polymorphic modifications.

6 : 8-*Dinitro*-2-(or 4)-*dichloromethyl*-4(or 2)-*chloromethylene*-1 : 3-*benzdioxin* (VI).—Potassium hydroxide (1·5 g.; 1 mol.), dissolved in 10 c.c. of alcohol, was added to a hot solution of 10 g. of the preceding dinitro-compound (1 mol.) in 100 c.c. of alcohol. An immediate rose-red colour was developed which quickly changed to brown. The mixture was gently warmed on the water-bath for a few minutes, a little water added, and the alcohol distilled off in steam; a viscid, reddish-brown solid then separated. By repeated crystallisation from small quantities of alcohol, 6 : 8-*dinitro*-2(or 4)-*dichloromethyl*-4(or 2)-*chloromethylene*-1 : 3-*benzdioxin* was obtained in well-formed, yellow rhombohedra, m. p. 144° (Found : C, 34·3; H, 1·4; N, 7·95; Cl, 29·8. $C_{10}H_5O_6N_2Cl_3$ requires C, 33·8; H, 1·4; N, 7·9; Cl, 29·9%). Like 6-nitro-2(or 4)-dichloromethyl-4(or 2)-chloromethylene-1 : 3-benzdioxin (II), it does not form an addition product with bromine.

2 : 4-*Bisdichloromethyl*-1 : 3-*benzdioxin*-6-*sulphonyl Chloride*.—The monohydrated acid (24 g.) and powdered phosphorus pentachloride (50 g.) were mixed and warmed on a water-bath for a few minutes, a brown oil being formed. This was poured slowly over ice. The *sulphonyl chloride*, which separated as a colourless solid, was dissolved in ether, from which, on addition of low-boiling petroleum, it separated in small, lustrous, colourless prisms, m. p. 105—106° (Found : Cl, 43·85. $C_{10}H_7O_4Cl_5S$ requires Cl, 44·3%).

When boiled with any alcohol, it reacts readily and yields the corresponding alkyl sulphonate. *Methyl* 2 : 4-*bisdichloromethyl*-1 : 3-*benzdioxin*-6-*sulphonate* separates from boiling methyl alcohol in lustrous flattened prisms, m. p. 110—111·5° (Found : Cl, 36·0. $C_{11}H_{10}O_5Cl_4S$ requires Cl, 35·8%), and the *ethyl* ester from boiling ethyl alcohol in small, compact prisms, m. p. 148—149·5° (Found : Cl, 34·6. $C_{12}H_{12}O_5Cl_4S$ requires Cl, 34·6%).

The sulphonyl chloride also reacts readily with ammonia and with aniline in boiling alcohol to form the *sulphonamide* and the *sulphonanilide*, which separate from boiling dilute alcohol in small, silvery prisms, m. p. 175·5° (Found : Cl, 37·0. $C_{10}H_9O_4NCl_4S$ requires Cl, 37·2%), and in small, colourless prisms, m. p. 166—167° (Found : N, 3·15; Cl, 30·9. $C_{16}H_{13}O_4NCl_4S$ requires N, 3·1; Cl, 31·0%), respectively.

THE QUEEN'S COLLEGE, OXFORD. [*Received, November 5th*, 1928.]

CCCCXXXII.—*Preparation of Diethylaminoethanol Esters of Diphenyl-2-carboxylic Acid and Derivatives.*

By Frank Bell.

Roberts and Johnson (*J. Amer. Chem. Soc.*, 1925, **47**, 1399) have directed attention to the marked anæsthetic action of diethylaminoethyl diphenate, and it was thought of interest to make the diethylaminoethyl esters of several related carboxylic acids.

Diphenyl-2-carboxylyl chloride reacted with diethylaminoethyl alcohol to give an *ester hydrochloride* with a well-marked anæsthetic action. The chlorides of diphenyl-4-carboxylic, fluorenone-4-carboxylic, and 2′-cyanodiphenyl-2-carboxylic acids furnished esters of perceptible but smaller action. *2′-Cyanodiphenyl-2-carboxylyl chloride* was obtained together with about 10% of diphenimide by the action of thionyl chloride on diphenamic acid (compare the action of thionyl chloride on diphenic acid; J., 1927, 1698).

$$\begin{matrix} C_6H_4\cdot CO_2H \\ | \\ C_6H_4\cdot CO\cdot NH_2 \end{matrix} \longrightarrow \begin{matrix} C_6H_4\cdot COCl \\ | \\ C_6H_4\cdot CN \end{matrix} + \begin{matrix} C_6H_4\cdot CO \\ | \\ C_6H_4\cdot CO \end{matrix}\!\!>\!NH$$

Diphenyl-2-carboxylyl chloride shows a great tendency to change into fluorenone during distillation. On the other hand, diphenoyl dichloride seems quite stable, although its boiling point is almost 50° higher. 2′-Cyanodiphenyl-2-carboxylyl chloride decomposed to only a slight extent; the 4-cyanofluorenone produced was found in the distillate. The considerable stability of this acid chloride is of interest, because the convenient process for obtaining 4-cyanofluorenone by the action of phosphorus pentachloride on phenanthraquinone monoxime (Borsche and Gander, *Ber.*, 1914, **47**, 2818) must depend on its intermediate formation.

Experimental.

Diphenyl-2-carboxylyl chloride was obtained as a pale yellow liquid, b. p. 163°/10 mm., when a solution of diphenyl-2-carboxylic acid in warm thionyl chloride was distilled in a vacuum (Found: C, 72·0; H, 4·1. Calc.: C, 72·1; H, 4·2%) (compare Schlenk and Bergmann, *Annalen*, 1928, **464**, 33). In two subsequent experiments the chloride decomposed completely during distillation with the formation of pure fluorenone. Bretscher, Rule, and Spence (this vol., p. 1502) have apparently had the same experience and are investigating the reaction in detail.

Interaction of this chloride and 2-aminodiphenyl in pyridine solution gave the corresponding *amide*, which crystallised from acetic acid in needles, m. p. 194° (Found: C, 85·5; H, 5·4. $C_{25}H_{19}ON$ requires C, 85·9; H, 5·4%).

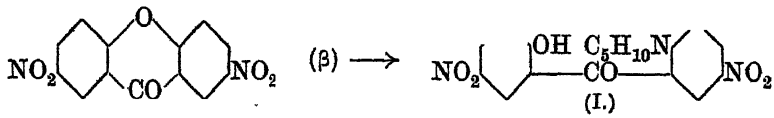
Diethylaminoethyl Diphenyl-2-carboxylate.—Diethylaminoethyl alcohol (5 g.) was added to a solution of the acid chloride (9·2 g.) in benzene (20 c.c.). The semi-solid product was warmed on the water-bath for ½ hour and evaporated in a vacuum, and the residual gum dissolved in cold water. The base was liberated with ammonia, extracted with ether, and distilled in a vacuum, giving a colourless liquid, b. p. 183°/1 mm., which contained some impurity (Found: C, 75·9; H, 7·6. $C_{19}H_{23}O_2N$ requires C, 76·8; H, 7·8%). It was treated in dry ether with hydrogen chloride (slightly less than the theoretical amount), the *hydrochloride of* diethylaminoethyl diphenyl-2-carboxylate being precipitated as a white powder, m. p. 109—110° (Found: HCl, 11·0. $C_{19}H_{23}O_2N$,HCl requires HCl, 10·9%). This hydrochloride is slightly hygroscopic, dissolves in a small amount of water to give a clear solution which becomes milky on dilution, and is markedly anæsthetic to the tongue.

Diethylaminoethyl Diphenyl-4-carboxylate.—4-Methyldiphenyl (Gomberg and Pernert, *J. Amer. Chem. Soc.*, 1926, **48**, 1375) was converted by oxidation with 2% aqueous permanganate solution (Jacobson, *Ber.*, 1895, **28**, 2547) into the corresponding acid, and this into the acid chloride (m. p. 114°) by thionyl chloride. When the acid chloride (4·6 g.) in benzene was treated with diethylaminoethyl alcohol (2·5 g.), a crystalline deposit was immediately obtained; the reaction was completed by warming the mixture for ½ hour. The product was collected and dissolved in water, impurities were removed by extraction with ether, the base was liberated with dilute sodium carbonate solution and extracted with ether, and the extract was dried with sodium sulphate and treated with hydrogen chloride, the *hydrochloride* of diethylaminoethyl diphenyl-4-carboxylate being precipitated as a white powder, m. p. 183° (Found: HCl, 11·2. $C_{19}H_{23}O_2N$,HCl requires HCl, 10·9%). This hydrochloride is extremely soluble in water, but the solution becomes milky on dilution.

2′-Cyanodiphenyl-2-carboxylyl Chloride.—Diphenamic acid (16·7 g.) and thionyl chloride were warmed together for ½ hour and the resultant solution was evaporated in a vacuum. A solution of the residual paste in a little benzene was filtered from the needle crystals of diphenimide (1·5 g.), m. p. 217—219°, and diluted with light petroleum, *2′-cyanodiphenyl-2-carboxylyl chloride* being precipitated as a white powder, which crystallised from carbon tetrachloride in stout prisms (10·6 g.), m. p. 84° (Found: C, 69·8; H, 3·2. $C_{14}H_8ONCl$ requires C, 69·6; H, 3·3%). On heating in a vacuum, it gave a pale yellow distillate, b. p. 222°/15 mm., containing about 3% of 4-cyanofluorenone, which remained undissolved by treatment with warm ether and then crystallised from alcohol in long, yellow needles, m. p. 243—244° (Borsche and Sander, *loc. cit.*, give 240°).

Alternatively, the distillate was dissolved in warm sodium hydroxide solution; the 4-cyanofluorenone remained undissolved, and the filtered solution, when poured into dilute hydrochloric acid, gave 2′-cyanodiphenyl-2-carboxylic acid, which crystallised from alcohol in stout needles, m. p. 173° (Werner and Siguet, *Ber.*, 1904, **37**, 4311, give 170—172°).

Diethylaminoethyl 2′-cyanodiphenyl-2-carboxylate was prepared in a similar way to the diphenyl-4-carboxylate. The *hydrochloride* was obtained as white plates, m. p. 189° (Found: HCl, 10·3. $C_{20}H_{22}O_2N_2$,HCl requires HCl, 10·2%), not hygroscopic though moderately easily soluble in water.



WELLCOME CHEMICAL RESEARCH LABORATORIES,
LONDON. [*Received, October 24th*, 1928.]

CCCCXXXIII.—*The Interaction of Piperidine with Nitro- and Halogenonitro-derivatives of Xanthone and Diphenylene Oxide.*

By RAYMOND JAMES WOOD LE FÈVRE.

THE interaction of various ethers with piperidine (Le Fèvre, Saunders, and Turner, J., 1927, 1168) suggested a method of comparing the strengths of attachment of radicals to the ethereal oxygen atom. In a similar way attempts have now been made to compare the activities of the ethereal oxygen atoms in diphenyl ether, xanthone, and diphenylene oxide. Owing to the stability of the parent substances the interactions of analogously constituted dinitro-derivatives (the nitro-groups being in each case in the *p*-positions to the ethereal oxygen atom) with piperidine were examined, and the following observations were made.

3 : 6-Dinitrodiphenylene oxide was recovered unchanged after several hours' boiling with piperidine or aniline. α- and β-Dinitroxanthones readily combined with piperidine in the cold, giving unstable yellow substances which, after a few hours' heating at 100°, became yellowish-orange piperidino-compounds (I). The piperi-

(I.)

dino-derivative from α-dinitroxanthone was not obtained in the pure state—a fact explained by the observation that 5 : 5′-*dinitro*-2′-*piperidino*-2-*hydroxybenzophenone* (I) lost piperidine at its melting point, the original dinitro-compound being regenerated. The

observations that β-dinitroxanthone could be recovered unchanged from boiling aniline, and tetranitroxanthone from boiling piperidine (in both cases coloured addition compounds were formed in the cold), may similarly be explained by decomposition of the respective expected products at temperatures lower than the boiling points of the reagents.

The interaction of piperidine with 4 : 4′-dinitrodiphenyl ether was fairly rapid and led to normal scission products (Le Fèvre, Saunders, and Turner, *loc. cit.*).

Tetrabromodinitroxanthone (Dhar, J., 1916, **109**, 747) reacted only slowly with piperidine.

In the hope of revealing the orienting influence of oxonium oxygen the dinitration of 2 : 7-dibromoxanthone was examined. The crude dinitration products obtained by the action of nitric acid in acetic acid and in excess of sulphuric acid were boiled with piperidine. Neither product yielded a perceptible quantity of piperidine hydrobromide, but instead 3 : 3′-dibromo-5 : 5′-dinitro-6-piperidino-6′-hydroxybenzophenone was formed. Therefore either oxonium salt formation does not affect nitration in this instance or sulphuric acid solutions of xanthones contain little quadrivalent oxygen. Since the xanthone structure does not hinder the normal activation of ethereal oxygen by *o*-nitro-groups, the possibility that in the above example nitro-groups in the 3 : 3′-positions could not render bromine atoms in the 2 : 2′-positions labile is small.

EXPERIMENTAL.

Action of Piperidine on α- and β-Dinitroxanthones.—The dinitroxanthones (Dhar, *loc. cit.*) were crystallised from phenol–alcohol.

(1) When α-dinitroxanthone (2 g.) was covered with piperidine (10 c.c.), a bright yellow substance was formed. (If isolated, this lost piperidine and became almost colourless.) The mixture, after 5 hours' heating on the water-bath, gave a deep red solution, from which, on dilution with water, an amorphous, yellow powder was obtained which could not be crystallised (Found: N, 10·8—11·1% in different samples).

(2) *β-Dinitroxanthone.* The preliminary development of colour was not so strong as in the preceding case and the yellow compound dissolved much more slowly. After 10 hours' heating at 100° the mixture was worked up as described above; the *5 : 5′-dinitro-2′-piperidino-2-hydroxybenzophenone* (I) obtained crystallised from acetic acid in yellow prisms, m. p. (rapid heating) 155° (Found: N, 11·4. $C_{15}H_{17}O_6N_3$ requires N, 11·3%).

When heated slowly, the substance melted at about 150° and changed to a red solid, which became yellower and finally melted at

about 250° to a brown liquid. 4 G. of (I) were therefore heated at 200°. Piperidine was evolved. The brown product was repeatedly extracted with boiling acetic acid and obtained as a cream-coloured powder (Found: N, 9·9. Calc., N, 9·8%), m. p. 260—262° (alone or mixed with β-dinitroxanthone).

5 : 5'-*Dinitro*-2'-*piperidino*-2-*acetoxybenzophenone* was prepared by refluxing the piperidino-compound in acetic acid–acetic anhydride, containing anhydrous sodium acetate, until the solution was almost colourless; it was precipitated by water, and crystallised from acetic acid in small needles, m. p. 253—255° (Found: N, 10·8. $C_{20}H_{19}O_7N_3$ requires N, 10·2%).

Action of Aniline on β-*Dinitroxanthone.*—When 10 g. of β-dinitroxanthone and 35 g. of aniline were mixed in the cold, a red addition compound formed. After 4 hours' boiling, however, β-dinitroxanthone, m. p. 261—262°, was recovered (Found: N, 10·0%). Similar results were obtained with methyl aniline and *o*-toluidine.

Dinitration of 2 : 7-*Dibromoxanthone.*—(*a*) To 1 g. of dibromoxanthone, dissolved in 25 c.c. of concentrated sulphuric acid, 4 c.c. of nitric acid (*d* 1·5) were added; small needles soon began to appear. Cold water was then added and the product was collected, boiled with hot water, and dried on the water-bath; m. p. 208—214° (Found: N, 7·0. Calc. for $C_{13}H_4O_6N_2Br_2$: N, 6·3%). The product reacted readily with piperidine, giving an oily piperidino-compound. The aqueous extracts of the reaction mixture contained no bromine precipitable by silver nitrate. (*b*) A solution of 1 g. of dibromoxanthone in 20 c.c. of nitric acid (*d* 1·5) and 20 c.c. of glacial acetic acid was warmed at 90° for 6 hours. The product, on treatment with piperidine, gave the same result as before, the absence of nitro-groups in any of the 1 : 3 : 6 : 8-positions being thus indicated.

2 : 7-*Dibromo*-4 : 6-*dinitroxanthone* was prepared by allowing 3 g. of dibromoxanthone to dissolve in 60 c.c. of fuming nitric acid at about 60°. The product was isolated in the usual way; after being extracted with a little benzene and crystallised from much benzene, it had m. p. 265—266° (Found: N, 6·4. $C_{13}H_4O_6N_2Br_2$ requires N, 6·3%). The action of piperidine on it gave a gummy product which could not be separated.

Nitration of β-*Dinitroxanthone.*—A solution of 10 g. of the dinitro-compound in 100 c.c. of sulphuric acid and 100 c.c. of fuming nitric acid was heated on a water-bath for 3 hours. Dilution with water then gave 2 : 4 : 5 : 7-*tetranitroxanthone* as a white powder, not molten at 300° (Found: N, 14·8. $C_{13}H_4O_{10}N_4$ requires N, 14·9%).

Action of Piperidine on 2 : 4 : 5 : 7-*Tetranitroxanthone.*—When the reactants were mixed in the cold a bright red colour developed, but

after the mixture had been heated for 8 hours at 100°, the tetranitro-compound was recovered (Found: N, 15·0%).

Piperidine reacted vigorously with 6-nitropiperonal, giving a tar from which no individual was isolated.

The author wishes to acknowledge the receipt of a grant from the Chemical Society which has helped to defray the cost of the materials used in this investigation.

UNIVERSITY COLLEGE, LONDON. [*Received, October 30th,* 1928.]

CCCCXXXIV.—*Researches on Residual Affinity and Co-ordination. Part XXXI. Molybdyl Bis-β-diketones.*

By GILBERT T. MORGAN and REGINALD ARTHUR SALTER CASTELL.

CHEMICAL literature contains references to two molybdenum derivatives of acetylacetone (Beilstein, 1918, Vol. I, p. 783): molybdous acetylacetone, formulated as $Mo(C_5H_7O_2)_2$ by Gach (*Monatsh.*, 1900, **21**, 112), and molybdyl bisacetylacetone, $MoO_2(C_5H_7O_2)_2$, first prepared by Rosenheim and Bertheim (*Z. anorg. Chem.*, 1903, **34**, 439). The composition indicated by Gach for his compound is extremely improbable, as his method of production is very similar to that employed by Rosenheim and Bertheim and in both experiments the starting material is some form of molybdenum trioxide. These two preparations have now been repeated and both products have been completely analysed and found to be identical.

In spite of the reducing action of acetylacetone on molybdenum trioxide and its hydrates, this reduction is subsidiary to the condensation occurring between unreduced trioxide and the diketone.

We have not been able to confirm the existence of molybdous acetylacetone, Gach's compound being undoubtedly molybdyl bisacetylacetone. The condensation has been shown to be a general reaction by the preparation of other molybdyl bis-β-diketones. Interaction occurs between molybdenum trioxide and such aliphatic diketones as propionylacetone, dipropionylmethane, and 3-ethylacetylacetone, and also with benzoylacetone and dibenzoylmethane containing aromatic radicals. Determinations of valency by Wardlaw's method (J., 1923, **123**, 969) show in all cases the presence of sexavalent molybdenum.

The discovery of a new hydrated molybdenyl monochloride by

Wardlaw and Wormell (J., 1924, **125**, 2370) afforded an opportunity of obtaining an acetylacetone derivative containing molybdenum in a lower state of oxidation, and by this means a hydrated *molybdenyl acetylacetone*, $MoO(C_5H_7O_2)_2,2\frac{1}{2}H_2O$, has been realised.

Experiments made with molybdenum pentachloride and molybdenum oxysulphate, $Mo_2O_3(SO_4)_2$, showed that the tendency for quinquevalent molybdenum to yield acetylacetone derivatives is comparatively slight, although a green compound having the composition $MoO_2(C_5H_7O_2)$ was obtained by the aërial oxidation of molybdenyl acetylacetone.

Experimental.

Molybdyl Bisacetylacetone, $MoO_2(Me\cdot CO\cdot CH\cdot COMe)_2$.—On analysing the yellow substance prepared by the interaction of molybdenum trioxide and acetylacetone, Gach obtained Mo, 32·90%, corresponding with $Mo(C_5H_7O_2)_2$, which requires Mo, 32·65%; the proportions of carbon and hydrogen were not determined by him. The preparation was repeated by leaving molybdenum trioxide and acetylacetone in a closed vessel for 4 days; yellow crystals had then appeared among the trioxide, which meanwhile had undergone slight reduction to the oxide. These crystals were dissolved out by alcohol and crystallised repeatedly from this solvent. The compound, which was also soluble in chloroform, benzene, toluene, or acetone to yellow solutions, was insoluble in water, ether, or light petroleum; it melted at 175° and decomposed above 230° (Found: C, 36·8; H, 4·0; Mo, 29·1. Calc. for $C_{10}H_{14}O_6Mo$: C, 36·8; H, 4·3; Mo, 29·5%). A valency determination by Wardlaw's method showed that the molybdenum present was sexavalent and not bivalent.

The preparation was modified by heating together under reflux, in a stream of carbon dioxide, 7 g. of molybdenum trioxide, 10 g. of acetylacetone, and 20 c.c. of alcohol. The trioxide gradually became blue by reduction and the liquid assumed a dark green colour. On cooling, golden-yellow crystals separated which were picked out from co-precipitated blue oxide and recrystallised from alcohol. The green mother-liquor yielded further crops of crystals (Found: Mo, 29·3%).

Rosenheim and Bertheim (*loc. cit.*) condensed acetylacetone in alcoholic solution with either powdered molybdic oxide dihydrate, dimethyl molybdate, or oxalomolybdic acid; on boiling for a short time, yellow microscopic crystals separated. Complete analysis of this preparation gave data corresponding with $MoO_2(C_5H_7O_2)_2$.

For comparison with the compound described by Gach we prepared molybdic trioxide dihydrate by adding successively to a 15%

solution of ammonium molybdate, 30% nitric acid, and ammonium nitrate until the solution contained 10% of this salt. After 8 days a small amount of dihydrate had separated, and precipitation was hastened by scratching the sides of the containing vessel (Found: Mo, 53·2. Calc. for $MoO_3,2H_2O$: Mo, 53·3%). Six grams of this dihydrate were heated for 4 hours with 7 g. of acetylacetone in alcoholic solution. The solution, filtered from blue oxide, yielded canary-yellow crystals insoluble in water but soluble in acetone, acetylacetone, benzene, or chloroform. From these media the product crystallised in six-sided plates melting at 175° and decomposing above 230° (Found: C, 36·7; H, 4·0; Mo, 29·5%). A mixed melting-point determination with the preparation from Gach's experiment showed that the two products were identical. In both experiments a portion of the trioxide was reduced to blue oxide, which, when suspended or dissolved colloidally in the yellow alcoholic solution, rendered this liquid green. If the product is crystallised from this solution, it may become contaminated with blue Mo_3O_8, only 8% of which would be required to give a molybdenum content of 32·90% corresponding with Gach's determination of the metal. Moreover, this impurity in the molybdyl bisacetylacetone induces thermal decomposition at a temperature much lower than the melting point of the pure substance.

Molybdyl Bispropionylacetone, $MoO_2(Et{\cdot}CO{\cdot}CH{\cdot}COMe)_2$.—When molybdenum trioxide (1·4 g.) and 2·2 g. of propionylacetone were heated together on the water-bath, a viscid mass resulted which was washed with ether and dissolved in chloroform; the product was precipitated from this solution by addition of light petroleum. When crystallised from alcohol, the substance separated in small, brown, rhombic crystals melting at 185°, whereas from hot chloroform more fusible green crystals separated (m. p. 130°). The *compound* was soluble in alcohol, chloroform, benzene, or acetone, but insoluble in water, ether, or light petroleum (Found: C, 40·5; H, 5·3; Mo, 27·0. $C_{12}H_{18}O_6Mo$ requires C, 40·7; H, 5·1; Mo, 27·2%).

Molybdyl Bisdipropionylmethane, $MoO_2(Et{\cdot}CO{\cdot}CH{\cdot}COEt)_2$.—A mixture of 1·4 g. of molybdenum trioxide and 2·5 g. of dipropionylmethane was heated until the trioxide had disappeared. The brown, viscid mass was washed with ether and extracted with alcohol. The alcoholic solution gave brown, six-sided plates, m. p. 78°, which were soluble in alcohol, acetone, chloroform, benzene, or toluene (Found: C, 44·25; H, 5·9; Mo, 25·4. $C_{14}H_{22}O_6Mo$ requires C, 44·0; H, 5·8; Mo, 25·1%).

Molybdyl Bis-3-ethylacetylacetone, $MoO_2(Me{\cdot}CO{\cdot}CEt{\cdot}COMe)_2$.—On heating together molybdenum trioxide and 3-ethylacetylacetone,

the mixture became brown and set to a viscid mass. Extraction as in previous examples removed a brown, crystalline solid, soluble in alcohol, acetone, chloroform, or benzene (Found: C, 43·3; H, 5·1; Mo, 25·8. $C_{14}H_{22}O_6Mo$ requires C, 44·0; H, 5·8; Mo, 25·1%).

Molybdyl Bisbenzoylacetone, $MoO_2(Ph{\cdot}CO{\cdot}CH{\cdot}COMe)_2$.—A mixture of 1·5 g. of molybdenum trioxide and 3·25 g. of benzoylacetone was warmed on the water-bath until the oxide had disappeared; the melt was then allowed to cool to a viscid mass. This, after being washed with ether, was extracted with alcohol; the extract yielded brown, rhombic crystals, m. p. 98°, soluble in acetone, chloroform, benzene, or toluene, but insoluble in water, ether, or light petroleum (Found: C, 53·8; H, 4·1; Mo, 21·3. $C_{20}H_{18}O_6Mo$ requires C, 53·3; H, 4·0; Mo, 21·3%).

Molybdyl Bisdibenzoylmethane, $MoO_2(Ph{\cdot}CO{\cdot}CH{\cdot}COPh)_2$.—On heating together 1·5 g. of molybdenum trioxide and 4·5 g. of dibenzoylmethane, a dark brown solid resulted which was washed successively with ether and alcohol, and the residue extracted with chloroform. From the cold extract a substance separated in light brown needles, m. p. 112°, soluble in alcohol, acetone, benzene, and toluene, but not in water, ether, or light petroleum (Found: C, 62·1; H, 4·3; Mo, 16·6. $C_{30}H_{22}O_6Mo$ requires C, 62·7; H, 3·8; Mo, 16·7%).

Molybdenyl Acetylacetone, $MoO(Me{\cdot}CO{\cdot}CH{\cdot}COMe),2\frac{1}{2}H_2O$.—By heating together for several hours 1·5 g. of molybdenyl chloride, $MoOCl,4H_2O$ (Wardlaw and Wormell, *loc. cit.*), and 1 g. of acetylacetone in alcoholic solution, a deep red liquid was obtained which on evaporation furnished brown, cubical crystals of hydrated *molybdenyl acetylacetone*. This product was recrystallised from alcohol and dried out of contact with air. It was soluble in water, but insoluble in anhydrous organic media. The dark red solution in alcohol or water was decolorised by dilute acids or alkalis; warm potassium ferrocyanide developed a yellowish-green fluorescence which changed to greenish-blue on cooling. The aqueous solution reduced cold silver nitrate and a valency determination indicated tervalent molybdenum. The compound decomposed indefinitely at about 150° (Found: C, 23·6; H, 4·2; Mo, 37·2; H_2O, 17·7. $C_5H_7O_3Mo,2\frac{1}{2}H_2O$ requires C, 23·4; H, 4·7; Mo, 37·5; H_2O, 17·6%). The water was estimated by heating the compound at 120° in a stream of nitrogen, the water evolved being collected in sulphuric acid.

In an endeavour to estimate the water by difference the compound was heated in the air at 120°; oxidation occurred slowly and a green residue was left. This substance, which was hygroscopic in

air, decomposed at 150° and dissolved to a green solution in water, alcohol, chloroform, or benzene (Found: C, 26·3; H, 3·8; Mo, 42·7. $C_5H_7O_4Mo$ requires C, 26·4; H, 3·1; Mo, 42·3%). Accordingly these data correspond with a derivative of quinquevalent molybdenum.

The authors desire to thank the Birmingham University Research Committee for a grant which has helped to defray the cost of this investigation.

CCCCXXXV.—*The Inhibition of Chemical Reactions. Part II. The Mechanism of the Inhibition of Esterification by Alkaline Substances.*

By KENNETH CLAUDE BAILEY.

THE author has recently demonstrated (this vol., p. 1204) that the reaction of ethyl alcohol and acetic acid takes place in two ways, (*a*) in the body of the liquid, and (*b*) on the surface of the containing glass vessel, and that the reaction of type (*b*) is inhibited by the presence of a trace of pyridine (one part or less per 10,000 parts), whilst the reaction of type (*a*) is only slightly affected, even by the addition of much larger quantities of pyridine.

The following mechanism is suggested. The surface of the vessel contains a number of active areas, at which pyridine molecules are adsorbed. Molecules of alcohol and acid, possessing sufficient energy to react, come into contact on an active area, forming a complex. In the absence of an inhibitor, this complex undergoes re-arrangement and breaks up into water and ethyl acetate. If a molecule of pyridine is present on the glass surface immediately beside the alcohol–acid complex, it attracts the acetic acid, withdraws it from the complex, and returns with it into the solution as pyridine acetate which dissociates, regenerating pyridine and acetic acid.

If we assume that a considerable proportion of the added pyridine is adsorbed on the surface, alcohol–acid complexes which form in the body of the liquid, with sufficient energy to react, are unlikely to meet a pyridine molecule when this base is present in small concentration, and reaction of type (*a*) is therefore scarcely affected.

This hypothesis, according to which the function of pyridine as an inhibitor depends on its nature as a weak base, has been tested by

experiments on the effect of quinoline, piperidine, ammonia, sodium hydroxide, benzyl chloride, *m*-cresol, benzene, chloroform, and hydrogen chloride on the reaction of ethyl alcohol and acetic acid.

Hydrogen chloride acted, of course, as a powerful positive catalyst, and was included as a control. Benzyl chloride, *m*-cresol, benzene, and chloroform either encouraged the reaction slightly or had no pronounced effect. Quinoline, piperidine, ammonia, and sodium hydroxide gave curves of exactly the same type as pyridine. The inhibiting action became more marked with increase of basic strength in passing from quinoline to pyridine and thence to piperidine, which almost completely inhibited reaction of type (*b*) in a concentration of about 1 in 30,000. The action of ammonia was rather less marked, and that of sodium hydroxide still less marked. This was no doubt due to the fact that these inorganic bases existed in solution as acetates to a greater extent than the organic bases.

The present interpretation, if correct, indicates that sodium and ammonium acetates, present in low concentration in alcoholic acetic acid solution, are highly dissociated on the glass surface, the basic constituent being adsorbed. Dissociation by adsorption has been observed by Bartell and Miller (*J. Amer. Chem. Soc.*, 1923, **45**, 1106), Miller (*ibid.*, 1924, **46**, 1150) and others.

Experimental.

The reaction mixture, which consisted of 9·275 mols. of ethyl alcohol per mol. of acetic acid, was placed in a specific gravity bottle of 25 c.c. capacity, closed by a ground-glass stopper with capillary aperture. This was completely filled and inverted in a wide test-tube containing solution of the same composition. The test-tube was closed by a loosely-fitting cork stopper and placed in an incubator at 43°. Five bottles of similar type were used, and as it had been shown by preliminary experiments that they gave almost identical esterification velocities, it was assumed that they possessed surfaces of equal activity.

Four or five mixtures, of which one was a control and the others contained varying amounts of inhibitor, were placed in the incubator simultaneously, so that slight variations of temperature affected equally all solutions of a series. At the close of an experiment the solutions were removed simultaneously, poured into cold water, and analysed as rapidly as possible.

In the table, esterification during 20 hours at 43° in absence of a catalyst is taken as standard (100), and other results are expressed in terms of this.

Conc. of added substance (mols. per 100,000 mols. of reaction mixture)	Nil.	3·34	8·34	83·4
Added substance.	Esterification.			
Quinoline	100	68·5	50·5	22·8

CCCCXXXVI.—*The Rotation Dispersion and Circular Dichroïsm of Caryophyllene Nitrosite.*

By STOTHERD MITCHELL.

Rotation Dispersion.—Deussen (*Annalen*, 1912, **388**, 161) found that caryophyllene nitrosite in benzene had $[\alpha]_D + 1626°$, and later (*J. pr. Chem.*, 1912, **85**, 487) he showed that this remarkably high value varies considerably with concentration and is always greater for sodium light than for mercury green. The latter observation and the blue colour of the substance led Tschugaev to suggest (*ibid.*, **86**, 547) that it might show the Cotton effect,* *i.e.*, a maximum of rotation on one side of its absorption band and a minimum on the other. To settle this point the author has examined the rotation dispersion of a solution of caryophyllene nitrosite in alcohol. The results obtained are shown in Fig. 1. The rotation reaches a maximum positive value about 6250 Å.U., becomes zero at 6800 Å.U., and is thereafter negative. Subsequent examination of the absorption spectra has revealed a narrow band with its head about 6800 Å.U., thereby confirming Tschugaev's contention.

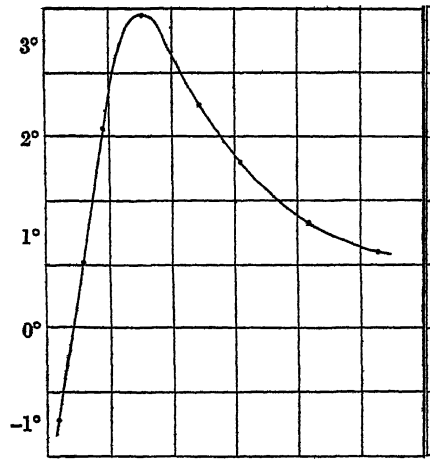
The caryophyllene nitrosite was prepared essentially as described by Schreiner and Kremers (*Pharm. Arch.*, 1899, **2**, 282); after crystallisation first from alcohol and then from aqueous acetone it melted at 115°. The alcoholic solution for rotation measurements contained 0·3113 g. of caryophyllene nitrosite per 100 g. of solution, and was contained in a 6-cm. tube. The readings were taken at 20° and the solution had $d_4^{20°}$ 0·7932. Eight different colours of light were used. A mercury-vapour lamp supplied the yellow, green,

* This phenomenon was first observed by Cotton (*Ann. Chim. Phys.*, 1896, **8**, 347) with alkaline solutions of copper tartrate and with potassium chromium tartrate.

and violet ones direct, and narrow strips of the spectrum from a Nernst lamp, corresponding to four other fainter mercury lines and to the red hydrogen line, were utilised in the manner described by Patterson (J., 1916, **109**, 1143). Readings were not continued beyond 6908 Å.U.; indeed, some difficulty was experienced in taking this. The values obtained were :

λ	4358	4916	5461	5790	6234	6563	6717	6908
α	0·78°	1·07°	1·71°	2·31°	3·27°	2·06°	0·66°	−0·97°
[α]	526°	722°	1154°	1559°	2207°	1390°	459°	−655°

FIG. 1.



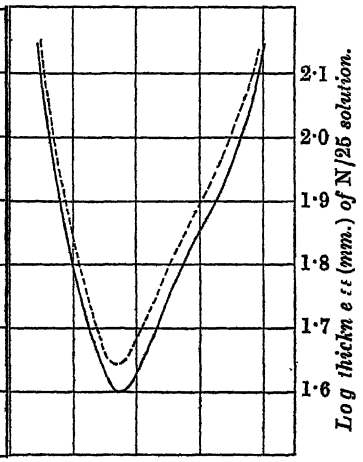


FIG. 2.

——— *Left-handed circularly polarised light.*
- - - - - *Right-handed* „ „ „

Circular Dichroïsm.—It has been shown by Fresnel that when a beam of plane-polarised light enters a transparent optically active medium it is resolved into two circularly polarised beams (one right-handed and the other left-handed). These travel with different velocities through the medium and combine again on leaving it to give a plane-polarised beam, the plane of polarisation of which is rotated through a certain angle from that of the original beam. Cotton found that in the region of selective absorption the emergent light from his coloured tartrate solutions was elliptically polarised, and he explained this by supposing that, besides travelling at different speeds, the circularly polarised components were absorbed to different extents. This view was subsequently confirmed by direct experiments with right- and left-handed circularly polarised monochromatic light, and by analogy with the dichroïsm of doubly refracting crystals the phenomenon was called circular dichroïsm.

Cotton's work on this subject has been extended to other metallic complexes of tartaric acid and to similar compounds of malic and lactic acids by McDowell (*Physical Rev.*, 1905, **20**, 163), Olmstead (*ibid.*, 1912, **35**, 31), and by Bruhat (*Ann. Physique*, 1915, **3**, 232; 1920, **13**, 36). The last author has also studied the phenomenon with the diphenyldithiourethanes of *d*- and *l*-borneol (*loc. cit.*) and with potassium irido-oxalate (*Bull. Soc. chim.*, 1915, **17**, 223). These, however, appear to be the only cases hitherto recorded, and it is therefore of interest to find a further example in caryophyllene nitrosite.

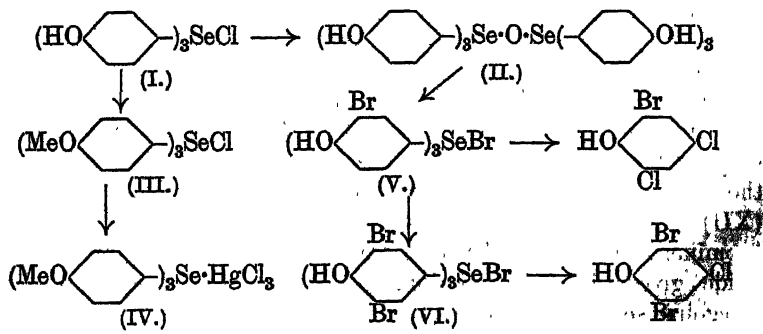
The above authors have concerned themselves more particularly with the variation of ellipticity (*i.e.*, the ratio of the axes of the elliptical light) with wave-length, but in the present investigation the absorption spectra for right- and left-handed light in the region of selective absorption have been studied. A Fresnel quartz tri-prism (*Ann. Chim. Phys.*, 1825, **28**, 147) was used to produce accurately both right- and left-handed circularly polarised light of equal intensity and contiguous to each other. The centre prism had a refracting angle of 150° and the base was 4″ long. The tri-prism was inserted between the collimator and the prism of a Hilger constant-deviation spectroscope, the collimator being displaced the necessary distance from its usual position. A 500-c.p. Pointolite lamp was employed as source of light. The height of the slit was adjusted with a V-shaped metal slide until the two spectra, produced one above the other by the tri-prism, just ceased to overlap. The Baly tube containing the caryophyllene nitrosite solution (*N*/25 in alcohol) was placed between the light source and the spectroscope slit. The eye-piece of the telescope was then removed and replaced by a single lens and camera, and a series of photographs was taken on a panchromatic plate for different thicknesses of solution. For calibration purposes the Baly tube was removed and a cobalt arc was photographed at the top and at the bottom of the plate. The results are represented graphically in Fig. 2. A distinct difference between the absorption spectra for right- and for left-handed circularly polarised light is apparent.

UNIVERSITY OF GLASGOW. [*Received, November 8th*, 1928.]

CCCCXXXVII.—*Interactions of Selenium Oxychloride and Phenols.*

By GILBERT T. MORGAN and FRANCIS HEREWARD BURSTALL.

IN two communications on organic selenium compounds formerly published from the Rostock Laboratories, Michaelis and Kunckell described certain reactions between selenium oxychloride or tetra-



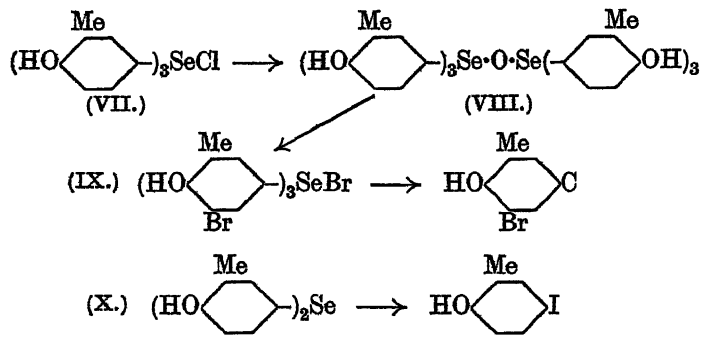
chloride and the phenols and phenolic ethers (*Ber.*, 1895, **28**, 609; 1897, **30**, 2823). The second of these publications contains a short description of condensations effected in ethereal solution between selenium oxychloride and phenol, β-naphthol and resorcinol, wherein the two monohydric phenols are stated to give selenides of the type $Se(R{\cdot}OH)_2$, R being C_6H_4 or $C_{10}H_6$, whilst resorcinol is alleged to yield a selenyl derivative, $SeO[C_6H_3(OH)_2]_2$.

On repeating the condensations we have been able to confirm these statements only in the case of β-naphthol, which gives the selenide, $Se(C_{10}H_6{\cdot}OH)_2$, in ethereal or preferably in chloroform solution.

The interactions of selenium oxychloride with phenol, the cresols, resorcinol, β-naphthol, and salicylic acid have now been investigated with the following results :

1. *Phenol.* When condensed with selenium oxychloride either in ethereal or in chloroform solution, phenol yields two isomeric *selenonium chlorides*, $[(HO{\cdot}C_6H_4)_3Se]Cl$, each containing ionisable chlorine precipitable as silver chloride and replaceable by other acidic radicals. The complex kation of these selenonium chlorides includes three phenolic hydroxyl groups which confer acidic properties on the chlorides so that these salts dissolve in aqueous caustic alkalis. From such solutions carbonic or acetic acid precipitates the amphoteric *oxide*, $[(HO{\cdot}C_6H_4)_3Se]_2O$, which redissolves in alkalis and reacts with acids to furnish the corresponding *bromide*, *nitrate*, *sulphate* and *chloroplatinate*.

The less soluble of the two selenonium chlorides, which is the main condensation product, is proved to be *tri-4-hydroxytriphenylselenonium chloride* (I) by progressive halogenation, for when neutralised with acetic acid, an alkaline solution of selenonium chloride deposits the *oxide* (II), which on bromination yields successively a tribrominated bromide (V) and a hexabrominated bromide (VI). With chlorine water the former of these bromides gives 2 : 4-dichloro-6-bromophenol, whereas the latter furnishes 4-chloro-2 : 6-dibromophenol.

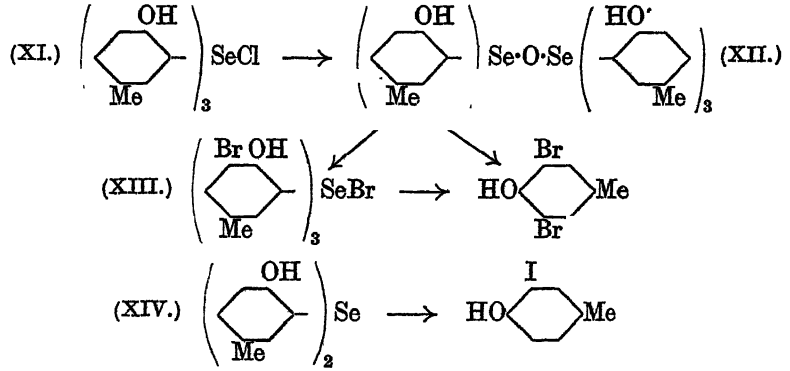


With the orientation of selenium and hydroxyl radicals established in these compounds it becomes possible to determine the constitution of trianisylselenonium chloride formerly prepared by Hilditch and Smiles (J., 1908, **93**, 1384), who, on employing a modified Friedel–Crafts reaction, obtained only selenonium salts from anisole, phenetole and resorcinol dimethyl ether.

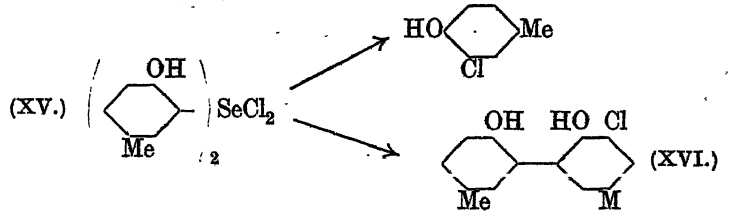
Tri-4-hydroxytriphenylselenonium chloride is methylated to the oily *tri-4-methoxytriphenylselenonium chloride* (III), which is converted into crystalline *mercurichloride* (IV). This complex salt is compared with a specimen prepared from trianisylselenonium chloride obtained by the method of Hilditch and Smiles. Both mercurichlorides melt as one compound at 68—70°.

Owing to the comparatively small yield of the more soluble selenonium chloride, the constitution of this salt was not determined; it is evident, however, that one, two, or three of its hydroxyl groups must be in the ortho-position with respect to selenium.

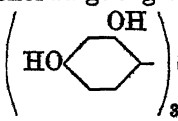
2. o-*Cresol.* The main product of the selenium oxychloride condensation is *tri-4-hydroxytri-3-methyltriphenylselenonium chloride* VII), the constitution of which is ascertained by progressive halogenation, starting with the corresponding *oxide* (VIII), which



yields a tribrominated bromide (IX) decomposed by chlorine water to furnish 5-chloro-3-bromo-*o*-cresol.



Di-4-hydroxydi-3-methyldiphenyl selenide (X), which arises as a by-product in the condensation of *o*-cresol and selenium oxychloride, is decomposed on boiling with hydriodic acid to yield 5-iodo-*o*-cresol.

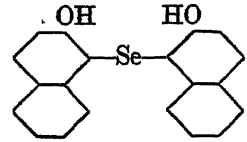


3. p-*Cresol.* A similar halogenation suffices to characterise *tri-2-hydroxytri-5-methyltriphenylselenonium chloride* (XI), a product of the selenium oxychloride condensation with *p*-cresol. Its *oxide* XII) furnishes a tribrominated bromide (XIII) with anhydrous bromine, whereas with bromine water this bromide or the original oxide gives rise to 3 : 5-dibromo-*p*-cresol. In addition to the foregoing selenonium chloride, *p*-cresol yields a considerable pro-

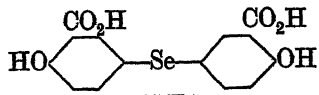
portion of *di*-2-*hydroxydi*-5-*methyldiphenyl selenide* (XIV), which on treatment with hydriodic acid gives 3-iodo-*p*-cresol.

The phenols have not in the condensations under review yielded chlorinated selenium derivatives of the type $Cl_2Se(R{\cdot}OH)_2$, although analogous compounds, $Cl_2Se(R{\cdot}OX)_2$, with X = CH_3 or C_2H_5, were obtained by Kunckell (*loc. cit.*) from anisole and phenetole. The absence of such chlorinated derivatives in the phenolic condensations is probably due to the readiness with which the phenols undergo chlorination. The mother-liquors from the selenide (XIV) contain 3-chloro-*p*-cresol and also a chlorinated dicresol (XVI). These substances may arise from the autochlorination of the hypothetical dichloroselenide (XV).

4. *Resorcinol.* In its condensation with selenium oxychloride resorcinol resembles phenol in giving rise to a selenonium chloride having the constitution  SeCl (XVII).



5. β-*Naphthol.* This condensation proceeds quantitatively in the sense of the equation



$$3C_{10}H_7{\cdot}OH + SeOCl_2 = Se(C_{10}H_6{\cdot}OH)_2 + C_{10}H_6Cl{\cdot}OH + HCl + H_2O.$$

Di-2-*hydroxydi*-1-*naphthyl selenide* (XVIII) is decomposed by

warm hydriodic acid into 1-iodo-β-naphthol and selenium, and a similar attack by bromine furnishes 1-bromo-β-naphthol.

(XVIII.)

(XIX.)

6. *Salicylic acid.* The condensation, effected preferably in the absence of solvent, leads to a disalicylyl selenide (*di-4-hydroxydiphenyl selenide di-3-carboxylic acid*, XIX).

The foregoing results indicate that between selenium oxychloride and the phenols two modes of reaction may take place, one manifested by phenol and resorcinol:

1. $3H{\cdot}R{\cdot}OH + SeOCl_2 = (HO{\cdot}R)_3SeCl + HCl + H_2O$,

and another exemplified by β-naphthol and salicylic acid:

2. $3H{\cdot}R{\cdot}OH + SeOCl_2 = Se(R{\cdot}OH)_2 + Cl{\cdot}R{\cdot}OH + HCl + H_2O$.

With *o*- and *p*-cresols both interactions occur concurrently.

EXPERIMENTAL.

1. *Phenol and Selenium Oxychloride.*—On adding selenium oxychloride (33·2 g.; 1 mol.), diluted with 50 c.c. of chloroform, to a well-stirred solution of phenol (56·4 g.; 3 mols.) in 500 c.c. of the same solvent, the mixture darkened rapidly and became opaque owing to separation of insoluble matter; meanwhile heat was generated and hydrogen chloride evolved. After an hour the yellow solution containing in suspension a deep red oil was refluxed until the insoluble product adhered to the containing vessel as a semi-solid, yellow gum. The chloroform was decanted and the residue triturated with acetone; the selenonium chloride then separated as a white powder which crystallised from alcohol–ether in small, white prisms, m. p. 232° (decomp.) (Found: C, 53·9; H, 4·0; Se, 19·8, 20·4; Cl, 9·2. $C_{18}H_{15}O_3ClSe$ requires C, 54·85; H, 3·8; Se, 20·1; Cl, 9·0%).

Tri-4-hydroxytriphenylselenonium chloride (I), a stable salt, dissolved readily in hot water to an almost neutral solution (p_H 5·7); it separated on cooling from hot water or alcohol in an anhydrous condition as a microcrystalline powder. It was insoluble in the other organic media. Cold, concentrated sulphuric acid dissolved it to a colourless solution with evolution of hydrogen chloride; on warming, yellow to green tints were developed. Aqueous ferric chloride gave a reddish-purple coloration, and aqueous caustic soda dissolved the selenonium chloride to a pale yellow solution from

which carbon dioxide or the calculated amount of dilute acetic acid precipitated white, amorphous *tri-4-hydroxytriphenylselenonium oxide* (II), decomp. 240° (Found: C, 58·2; H, 4·2; Se, 21·9, 21·7. $C_{36}H_{30}O_7Se_2$ requires C, 59·0; H, 4·1; Se, 21·6%).

This complex amphoteric oxide was insoluble in neutral organic media but furnished salts with mineral acids. The sulphate and bromide, decomposing respectively at 269—270° and 237°, are prepared by adding the appropriate acid to alkaline solutions of the oxide. The bromide crystallised from alcohol–ether in white needles. With an alcoholic solution of the selenonium chloride, silver nitrate gave a quantitative deposition of silver chloride; the filtrate on evaporation and addition of ether yielded the white, crystalline, water-soluble *nitrate*, m. p. 138—139° (decomp.) (Found: N, 3·4. $C_{18}H_{15}O_6NSe$ requires N, 3·3%).

From a hot aqueous solution of selenonium and platinic chlorides an orange *chloroplatinate* crystallised, on cooling, in lustrous needles, decomp. 244° (Found: Pt, 17·4. $C_{36}H_{30}O_6Cl_6Se_2Pt$ requires Pt, 17·4%).

Tri-4-methoxytriphenylselenonium chloride (III). Five g. of methyl iodide were added to a solution of tri-4-hydroxytriphenylselenonium chloride (3·9 g.) and sodium methoxide (1 g. of sodium in 200 c.c. of methyl alcohol), the mixture being refluxed until acid to litmus. After being acidified strongly with hydrochloric acid, the mixture was distilled in steam, and the residue was dissolved in chloroform, dried, and evaporated to a yellow, uncrystallisable gum which, however, yielded *tri-4-methoxytriphenylselenonium mercurichloride* (IV), m. p. 68—70°, identical with the mercurichloride obtained from trianisylselenonium chloride prepared by the method of Hilditch and Smiles (*loc. cit.*) (Found: Cl, 14·4. $C_{21}H_{21}O_3Cl_3SeHg$ requires Cl, 15·05%).

Tri-3-bromotri-4-hydroxytriphenylselenonium bromide (V). Tri-4-hydroxytriphenylselenonium oxide was stirred gradually into excess of bromine and when the vigorous reaction had subsided the mixture was evaporated to dryness; the dry residue after trituration with ether left a white, brominated product which was dissolved in hot alcohol. This solution deposited a crop of impure hexabrominated bromide (*v. infra.*); the mother-liquor on evaporation and addition of ether yielded the tribrominated bromide as a white, microcrystalline powder. After repeated crystallisation this *bromide* melted at 251° to a red liquid (Found: Br, 47·4; Se, 11·4. $C_{18}H_{12}O_3Br_4Se$ requires Br, 47·4; Se, 11·7%). The tribrominated bromide was insoluble in water and organic media except alcohol, but dissolved readily in aqueous caustic soda; dilute acetic acid precipitated the complex oxide (m. p. 198°), which was decomposed

readily by chlorine water, yielding 2 : 4-dichloro-6-bromophenol, m. p. 67—68°.

Tri-3 : 5-dibromotri-4-hydroxytriphenylselenonium bromide (VI) was precipitated in the more sparingly soluble fraction from the foregoing experiment in combination with the tribrominated bromide. Repeated evaporation with bromine and crystallisation from alcohol led to the pure hexabrominated *bromide*, obtained in sparingly soluble, lustrous, white prisms, decomp. 261° (Found: Br, 61·6. $C_{18}H_9O_3Br_7Se$ requires Br, 61·35%). Chlorine water eliminated selenium from this hexabrominated salt and furnished 4-chloro-2 : 6-dibromophenol, m. p. 92°.

Isomeric trihydroxytriphenylselenonium chloride,

$$(HO{\cdot}C_6H_4)_3SeCl,2H_2O.$$

The acetone filtrates from tri-4-hydroxytriphenylselenonium chloride yielded on evaporation an isomeric *selenonium chloride*, crystallising with two molecular proportions of water and decomposing at 125° (Found: C, 50·6; H, 4·5; Se, 18·6; Cl, 8·0; loss on heating at 110°, 9·5. $C_{18}H_{15}O_3ClSe,2H_2O$ requires C, 50·3; H, 4·45; Se, 18·4; Cl, 8·4; loss, 8·4%). This salt dissolved in hot water, but separated on evaporation as a colourless, viscous gum setting to a glass over sulphuric acid. It possessed the chemical properties of the tri-*p*-isomeride, but the small yield (1—2 g.) rendered orientation experiments impracticable. From a solution in aqueous caustic soda, carbon dioxide or dilute acetic acid precipitated the amorphous oxide (decomp. 180°), and methylation yielded successively a viscid trimethoxytriphenylselenonium chloride and a mercurichloride (m. p. 54—55°).

2. o-*Cresol and Selenium Oxychloride.*—Selenium oxychloride (16·6 g.; 1 mol.) in 50 c.c. of chloroform was stirred into a solution of *o*-cresol (33·6 g.; 3 mols.) in 400 c.c. of the same solvent. After an hour the mixture was refluxed until the heavy, red oil which first separated became converted into solid selenonium salt. The chloroform solution was decanted; the residue, after being washed with acetone, crystallised from alcohol–ether as a white powder, decomp. 231° (yield, 10 g.) (Found: C, 57·7; H, 5·1; Cl, 7·9; Se, 17·8. $C_{21}H_{21}O_3ClSe$ requires C, 57·8; H, 4·9; Cl, 8·1; Se, 18·2%).

Tri-4-hydroxytri-3-methyltriphenylselenonium chloride (VII) was insoluble in water and most organic solvents but dissolved in alcohol. Alcoholic ferric chloride gave no coloration, but warm concentrated sulphuric acid produced a green tint. When an alkaline solution of this chloride was treated with carbon dioxide or dilute acetic acid the corresponding *selenonium oxide* (VIII) was precipitated as an amorphous powder, decomp. 236° (Found: Se, 19·6. $C_{42}H_{42}O_7Se_2$ requires Se, 19·4%).

The addition of nitric acid to an alkaline solution of this oxide gave the *nitrate*, decomp. 224°, which was crystallised from alcohol (Found: N, 3·3. $C_{21}H_{21}O_6NSe$ requires N, 3·0%).

Tri-5-bromotri-4-hydroxytri-3-methyltriphenylselenonium bromide (IX) was produced on stirring small quantities of the foregoing oxide into excess of bromine. Hydrogen bromide was evolved and after the violent reaction had subsided the mixture was taken to dryness; after being triturated with ether, the white residue was crystallised from boiling alcohol, the brominated *bromide* separating in silvery prisms darkening and decomposing at 253° (Found: Br, 44·8. $C_{21}H_{18}O_3Br_4Se$ requires Br, 44·6%). When added to an alkaline solution of this brominated selenonium bromide, dilute acetic acid precipitated the amorphous oxide, which was decomposed by chlorine water, giving 5-chloro-3-bromo-*o*-cresol (m. p. 48°).

Di-4-hydroxydi-3-methyldiphenyl selenide (X). After tri-4-hydroxytri-3-methyltriphenylselenonium chloride had been separated in the selenium oxychloride condensation, the chloroform filtrate was evaporated to a viscid oil and distilled in steam. A little unchanged *o*-cresol appeared first, but the main distillate consisted of 5-chloro-*o*-cresol (m. p. 48°). The brown, gummy residue was extracted repeatedly with petroleum (b. p. 80—100°) and on cooling the solution an oil separated which after repeated extractions solidified in small, pale yellow needles, m. p. 98—99° (Found: C, 56·9; H, 4·9; Se, 26·7. $C_{14}H_{14}O_2Se$ requires C, 57·3; H, 4·8; Se, 27·0%).

When boiled with concentrated hydriodic acid, the dihydroxyditolyl selenide readily decomposed with elimination of black selenium and production of 5-iodo-*o*-cresol (m. p. 72°).

Although insoluble in water, this complex selenide dissolved readily in either aqueous caustic soda or the common organic solvents. Concentrated sulphuric acid gave a deep green tint even in the cold.

3. p-*Cresol and Selenium Oxychloride.*—*p*-Cresol (67·2 g.; 3 mols.), dissolved in 500 c.c. of chloroform, was treated with selenium oxychloride (33·2 g.; 1 mol.) diluted with 50 c.c. of the same solvent. The well-stirred mixture slowly assumed a deep red colour, hydrogen chloride was evolved and selenonium chloride separated. The mixture was refluxed, and the precipitate washed with acetone and ether (yield, 17·5 g.). After crystallisation from hot alcohol and drying in a vacuum desiccator, the selenonium chloride retained alcohol of crystallisation which was removed at 110° (Found: C, 57·85; H, 6·0; Cl, 7·1; Se, 15·45; loss on heating at 110°, 14·4. $C_{21}H_{21}O_3ClSe,1\frac{1}{2}C_2H_6O$ requires C, 57·0; H, 6·0; Cl, 7·0; Se, 15·7;

loss, 13·7%). This preparation gave the iodoform reaction with iodine in aqueous caustic soda.

Tri-2-hydroxytri-5-methyltriphenylselenonium chloride (XI), which decomposed at 260—265°, was insoluble in water but dissolved in hot alcohol or in aqueous caustic soda. Concentrated sulphuric acid developed no coloration in the cold but, on warming, an olive-green tint changing to deep red. Alcoholic ferric chloride gave a faint olive-green tint. The corresponding complex *oxide* (XII), a white, amorphous powder, decomp. 160°, was precipitated by carbon dioxide or dilute acetic acid from an alkaline solution of the foregoing chloride (Found: Se, 19·1. $C_{42}H_{42}O_7Se_2$ requires Se, 19·4%). With bromine water this complex oxide was readily decomposed, yielding 3 : 5-dibromo-*p*-cresol (m. p. 48°).

Tri-3-bromotri-2-hydroxytri-5-methyltriphenylselenonium bromide (XIII), obtained by the action of anhydrous bromine on the oxide in the manner employed for the analogue from *o*-cresol, separated from hot alcohol in pinkish-white prisms, decomp. 195° (Found: Br, 45·0. $C_{21}H_{18}O_3Br_4Se$ requires Br, 44·6%).

Di-2-hydroxydi-5-methyldiphenyl selenide (XIV). The chloroform filtrate from the selenium oxychloride condensation after separation of the selenonium chloride was evaporated nearly to dryness and distilled in steam. The distillate contained 3-chloro-*p*-cresol (b. p. 196°/760 mm.; yield, 12·0 g.). The dried residue was extracted repeatedly with petroleum (b. p. 40—60°). Repeated crystallisation of the extracted material yielded the white *selenide*, m. p. 111° (Found: C, 57·0; H, 4·8; Se, 26·9. $C_{14}H_{14}O_2Se$ requires C, 57·3; H, 4·8; Se, 27·0%).

This complex aromatic selenide, although insoluble in water, dissolved readily in the common organic solvents. Cold concentrated sulphuric acid gave a deep green tint, becoming red on warming; alcoholic ferric chloride developed a deep green coloration. Concentrated hydriodic acid eliminated selenium from the selenide and yielded 3-iodo-*p*-cresol (m. p. 37—38°).

5-Chloro-4 : 4'-dihydroxy-3 : 3'-ditolyl (XVI). This singular by-product separated from the last fractions of the foregoing diaryl selenide in yellow clumps and after crystallisation from petroleum was obtained as a white, crystalline powder, m. p. 129—130° (yield, about 1 g.) [Found: C, 67·9; H, 4·85; Cl, 13·9; *M* (in camphor), 254·7. $C_{14}H_{13}O_2Cl$ requires C, 67·6; H, 5·3; Cl, 14·3%; *M*, 248·5].

4. *Resorcinol and Selenium Oxychloride.*—Resorcinol (33 g.; 3 mols.), suspended in 1000 c.c. of chloroform or dissolved in glacial acetic acid, was treated with selenium oxychloride (16·6 g.; 1 mol.) diluted with 100 c.c. of the same solvent. Each drop of the oxy-

chloride produced a transient green tint and a white precipitate separated. The solid portion of the jelly-like mixture was pressed and dissolved in acetone. On evaporation this solution yielded a selenonium chloride as a white powder. This product was dissolved in alcohol, and a large volume of acetone added; the selenonium chloride then separated slowly with acetone of crystallisation (1 mol.). With ammoniacal iodine the chloride yielded iodoform, thus confirming the presence of acetone. The substance melted at 206° (yield, 30 g.) (Found: C, 49·4; H, 4·5; Cl, 7·0; Se, 16·1; loss on heating at 110°, 12·1. $C_{18}H_{15}O_6ClSe,C_3H_6O$ requires C, 50·4; H, 4·2; Cl, 7·1; Se, 15·8; loss, 11·6%).

Tri-2 : 4-*dihydroxytriphenylselenonium chloride* (XVII) dissolved in boiling water to a pale red solution which set to a jelly on cooling. It also dissolved readily in alcohol or aqueous caustic soda but was only sparingly soluble in acetone or glacial acetic acid and insoluble in chloroform or benzene. Aqueous ferric chloride developed a reddish-purple coloration, warm concentrated sulphuric acid gave a green tint, and bromine water decomposed this selenonium chloride completely.

5. β-*Naphthol and Selenium Oxychloride.*—Selenium oxychloride (16·6 g.; 1 mol.), diluted with 100 c.c. of chloroform, was stirred into 43·2 g. of β-naphthol (3 mols.) in 700 c.c. of this solvent. The mixture became warmer and darker and finally almost solid owing to the separation of organic selenide (yield, 35 g.). This product crystallised from acetone in lustrous, colourless prisms, melting at 186° to a red liquid (Found: C, 65·5; H, 3·65; Se, 22·0. $C_{20}H_{14}O_2Se$ requires C, 65·7; H, 3·9; Se, 21·7%).

Although insoluble in chloroform, benzene, ether, or water, *di*-2-*hydroxydi*-1-*naphthyl selenide* (XVIII) dissolved readily in acetone and sparingly in hot alcohol or glacial acetic acid. Cold concentrated sulphuric acid developed a green tint, but alcoholic ferric chloride had no colour effect. This complex selenide dissolved readily in aqueous caustic alkalis and was reprecipitated unchanged by acids. Evaporation of the chloroform filtrate from di-2-hydroxydi-1-naphthyl selenide and distillation in steam of the red residue gave 17 g. of 2-chloro-β-naphthol (m. p. 70°).

6. *Salicylic Acid and Selenium Oxychloride.*—Salicylic acid (41·4 g.; 3 mols.) and selenium oxychloride (16·6 g.; 1 mol.) were heated and stirred in an open basin so long as hydrogen chloride was evolved and until the yellow mixture had assumed a brown tint. After cooling, the hard product was powdered and extracted with hot benzene to remove ill-defined by-products, unchanged salicylic acid and 5-chlorosalicylic acid (m. p. 166—167°). The pale yellow residue (20 g.) was crystallised repeatedly from aqueous

alcohol, *disalicylyl selenide* (*di-4-hydroxydiphenyl selenide di-3-carboxylic acid*, XIX) being obtained in small, yellowish-white, micaceous plates, sintering at 250° and decomposing at 272° (Found: C, 47·4; H, 2·9; Se, 23·2. $C_{14}H_{10}O_6Se$ requires C, 47·5; H, 2·85; Se, 22·4%). Although readily soluble in alcohol, ether, acetone, or glacial acetic acid, the disalicylyl selenide is insoluble in water, chloroform, or benzene. It dissolved readily in aqueous caustic or carbonated alkalis. The very soluble sodium salt was precipitated by ether from alcoholic solution as a hygroscopic precipitate, becoming green on exposure. Cold concentrated sulphuric acid and the selenide developed a green coloration which deepened on warming. Ferric chloride and an alcoholic solution of the selenide gave an intense bluish-violet coloration.

Experiments on the condensation of selenium oxychloride with *m*-cresol, α-naphthol, and 2-hydroxy-3-naphthoic acid failed to furnish well-defined products.

CHEMICAL RESEARCH LABORATORY,
TEDDINGTON, MIDDLESEX. [*Received, November 15th*, 1928.]

CCCCXXXVIII.—*The Electrical Conductivities of Some Uni-univalent Salts in Benzonitrile. Evidence for the Incomplete Dissociation of Strong Electrolytes and the Applicability of the Law of Mass Action to their Dissociation.*

By AUSTIN RAYMOND MARTIN.

IN view of Debye and Hückel's theory and its recent developments, considerable significance attaches to the study of the conductivity of salts in non-aqueous solution. The earlier relevant data cannot be regarded as trustworthy, and it is only within the last few years that satisfactory measurements of conductivity in non-aqueous solution have been recorded (see Kraus and Bishop, *J. Amer. Chem. Soc.*, 1922, **44**, 2206; Morgan and Lammert, *ibid.*, 1924, **46**, 1117; Philip and Oakley, J., 1924, **125**, 1189; Frazer and Hartley, *Proc. Roy. Soc.*, 1925, *A*, **109**, 351; Walden, Ulich, and Laun, *Z. physikal. Chem.*, 1925, **114**, 275; Walden, Ulich, and Busch, *Z. physikal. Chem.*, 1926, **123**, 429). The present investigation was undertaken with the object of providing additional accurate data in this field, more especially over a wide range of temperature (compare Philip and Oakley, *loc. cit.*; Walden, *loc. cit.*). Benzonitrile was chosen as solvent because (1) it is easily purified, (2) it is inert and not hygroscopic, and (3) its b. p. is fairly

high. Moreover, it is desirable to examine a solvent less closely related to water than the alcohols which have been used in most of the accurate conductivity measurements in non-aqueous solutions. As solutes, potassium, sodium, and lithium iodides, lithium bromide, and silver nitrate were employed. The solubility of inorganic uni-univalent salts in benzonitrile is, with the exception of silver nitrate, not great, and the above are the only salts sufficiently soluble for the purpose. Among previous work on conductivities in benzonitrile, mention may be made of that of Walden on tetraethyl- and tetrapropyl-ammonium iodides (*Z. physikal. Chem.*, 1906, **54**, 189; **55**, 710) and of Dutoit on sodium iodide (*Z. Elektrochem.*, 1906, **12**, 643), all at 25°. The value of Λ_0 found by the author for sodium iodide at 25° is some 10% lower than Dutoit's, and the author's results yield a value for the mean ionic radius calculated from the Debye–Hückel theory of $3{\cdot}72 \times 10^{-8}$ cm., whereas Dutoit's give one of $6{\cdot}30 \times 10^{-8}$ cm.

Experimental.

Apparatus.—The bridge was set up as in the usual Wheatstone arrangement, the source of the current being connected to the sliding contact and the junction of the standard resistance with the cell. The sliding contact was earthed.

The bridge wire was of the drum type, 5 metres long, of 32 ohms resistance, and having an ebonite hood, made by Leeds and Northrup; it was calibrated by the method of Strouhal and Barus and had no appreciable error. The standard resistance was of the dial pattern, maximum resistance 11,110 ohms, accurate to 0·04%, made by Cambridge and Paul. The telephone was of 120 ohms resistance, made by Brown. The source of current was a valve oscillator made by the author and giving a pure sine-wave alternating current of frequency 1000 cycles per second. It was electromagnetically shielded from the bridge.

The condensers placed in parallel with the standard resistance in order to balance the capacity of the cell were (i) a step-up mica condenser of maximum capacity 1·0 microfarad, and (ii) a variable air condenser, of maximum capacity 0·001 microfarad, for fine adjustment: usually the air condenser alone sufficed.

The cells. Of the three cells used, two, one of lead glass and one of Pyrex (Cells P I and P II), were of the pipette type designed on the lines laid down by Washburn (*J. Amer. Chem. Soc.*, 1916, **38**, 2431). The platinum electrodes (3 cm. in diameter and 0·5 cm. apart) were grey-platinised. The capacity of each cell was about 20 c.c. The third cell (Cell III) was a stoppered, round-bottomed, Pyrex-glass bottle of about 20 c.c. capacity, the electrodes—two

grey-platinised platinum discs 1 cm. in diameter and about 1 cm. apart—being sealed in through the sides. The cell constants of the pipette cells were 0·034014 and 0·041729, and of the other cell 0·19057. The pipette cells were used for all except the most concentrated solutions, since with small electrodes satisfactory minima were not obtained with solutions of low conductivity (compare Washburn, *loc. cit.*).

Temperature Control.—The thermostats were controlled by mercury–toluene gas-regulators and were constant to $\pm$ 0·01°. A layer of oil was placed on the surface of those at temperatures of 50° and above. The bath at 0° was maintained with distilled water and ice which had been washed with distilled water.

Determination of Cell Constants.—The constant of Cell III was determined at 25° with an N/100-potassium chloride solution prepared according to Parker and Parker (*J. Amer. Chem. Soc.*, 1924, **46**, 312). The flask and small weighing bottle used were of hard glass and were steamed out before use. The water had a specific conductivity of 1×10^{-6} mho. The potassium chloride (A.R. quality) was recrystallised twice from conductivity water, fused in a platinum dish, and ground in an agate mortar. Two samples were prepared and both led to the same result for the cell constant. The constants of the two pipette cells could not be determined with this solution, since its conductivity was great enough to be outside the range of satisfactory minima. They were therefore obtained by intercomparison with Cell III. All three cells were filled with a solution consisting of 100 c.c. of N/100-potassium chloride and 900 c.c. of alcohol (Morgan and Lammert, *J. Amer. Chem. Soc.*, 1923, **45**, 1692); the ratio of the resistance of the cells so filled was the ratio of their cell constants, and, the constant of one of them being known, those of the others were readily calculated.

The ratio of the cell constants was found to be the same at all the temperatures used, and, since the dimensions of the pipette cells and Cell III were very different, this indicates that the constants of all of them were not appreciably altered by temperature. The values of the cell constants determined at 25° were therefore used for all the temperatures investigated; they were redetermined at frequent intervals and were found not to alter appreciably, except that of Cell P I which changed a little in the first month or so after manufacture.

Preparation of the Salt Solutions.—The solutions were made in 50 or 100 c.c. flasks with ground stoppers. If they were to be kept for any length of time, the stopper was covered by a cap and waxed. The flasks were specially selected not to have capillaries which might retain water. After thorough cleaning, they were washed

repeatedly with conductivity water and then with redistilled absolute alcohol and placed upside-down in a steam oven to dry. They were rapidly removed to a desiccator containing phosphoric oxide, the desiccator was evacuated, and purified, dry air was admitted after the flasks had cooled.

All the solutions were made up by weight. The weight of dissolved salt was subtracted from the weight of solution, and from the resulting weight of pure solvent and the density of pure benzonitrile at the appropriate temperature the volume concentrations were calculated, *i.e.*, electrostriction was taken to be negligible. This assumption was found to be justified in the case of an $N/100$-silver nitrate solution, which was the highest concentration used.

The densities of benzonitrile at temperatures between 0° and 70° were found to be as follows:

Temp. ...	0°	25°	40°	50°	55°	70°
d_4^t	1·0222	1·0005	0·9872	0·9778	0·9739	0·9600

The stock solution was made by adding to a weighed amount of benzonitrile a small weighing bottle containing a weighed amount of the salt and shaking until the salt had dissolved. Potassium iodide was exceptionally slow in dissolving and sometimes had to be shaken over-night. The quantity of salt taken was of the order of 0·05—0·1 g. and was weighed to 0·01 mg., the method of oscillations being used.

The more dilute solutions were made by adding to flasks containing a weighed quantity of benzonitrile the requisite quantity of a more concentrated solution and weighing again. The weights were not reduced to *vacuo* since the same percentage error occurs both in the weight of pure solvent and in the weight of the previous dilution added, the resultant error being zero. No dilute solution was derived from a stronger solution which had previously been used for any other purpose. All the transferences were carried out in pipettes which had been cleaned and dried in the same way as the flasks, except that instead of cooling them in a vacuum desiccator, a stream of purified and dry air was drawn through them. When not in use, the ends of the pipettes were closed with rubber caps in order to prevent access of moist air. No pipette was used more than once in a series of dilutings, and a suitable guard was inserted between the mouth and the pipette. Experiment showed that the pouring of benzonitrile from one vessel to another in an ordinary room did not noticeably alter its conductivity.

Whetham's method of preparing solutions for conductivity measurements (*Phil. Trans.*, 1900, *A*, **194**, 321), in which successive portions of a concentrated salt solution are added from a weight pipette to a known volume of pure solvent in the cell, was inapplic-

able in the present work for the following reasons: (1) As will be explained later, it was necessary for the cell to have been filled with a concentrated solution before the more dilute solutions were measured. (2) Most of the salts investigated were so sparingly soluble in benzonitrile that large volumes of a stock solution would have had to be added in order to obtain the more concentrated solutions, thereby altering the effective constant of the cell.

The method used in the present work has none of the defects of the Ostwald–Arrhenius method, except the slight uncertainty as to the magnitude of the solvent correction.

Conductivity Measurements.—Before a series of measurements the cells were cleaned with chromic–sulphuric acid mixture, washed with conductivity water, and warmed several times with conductivity water. They were then washed thoroughly with redistilled absolute alcohol and dried by being warmed to about 80° and having a current of purified dry air drawn through them. Cell III was dried by leaving it in a steam-oven and then allowing it to cool in a vacuum desiccator in the same way as the flasks used in making up the solutions. Between individual measurements in a single series of dilutions, the method of washing and drying the cell was the same, except that treatment with cleaning mixture and water was omitted. As recommended by Morgan and Lammert (*loc. cit.*, 1923), the electrodes were kept short-circuited during the process of cleaning and drying.

During the conductivity measurements, the bridge was approximately set and the current switched off for a minute; the fine setting was then made in about two seconds. This procedure was adopted in order to avoid errors due to the heating effect of the current. Perfect minima were always obtained, and the bridge could be set to 0·01% of its length.

With each salt at least two series of measurements starting from different stock solutions were made.

In the case of potassium iodide, a photochemical reaction took place which resulted in a minimum in the equivalent conductivity at high dilutions, but this was avoided by painting the cell with Brunswick black. It was also found that the conductivity of dilute potassium iodide solutions was not constant if the measurements were carried out beginning with the most dilute solution and working up to the most concentrated. If the measurements proceeded in the reverse order the conductivities were quite constant. This phenomenon was traced to adsorption on the electrodes. On immersion in a concentrated solution, an amount of electrolyte is adsorbed the removal of which does not noticeably alter the conductivity of the solution. The amount of adsorbed electrolyte does

not vary appreciably with its concentration in the solution, and consequently in the more dilute solutions the electrolyte is neither further adsorbed on the electrodes nor given up to the solution. This latter point was proved by measuring the conductivity of the pure solvent in the cell, and then filling it with a concentrated solution, washing it in the way usual between two measurements, and measuring the conductivity of the pure solvent again. The two values thus obtained were identical. This observation is in agreement with the experience of Randall and Scott (*J. Amer. Chem. Soc.*, 1927, **49**, 636), who, in investigating the variation of cell constant with resistance and other factors, found that the quantity of electrolyte adsorbed did not vary appreciably with the concentration of the surrounding solution. All the measurements were therefore carried out in the dark and (except in the case of silver nitrate, where no trouble was experienced) beginning with the most concentrated solution and proceeding to the most dilute.

Solvent Correction.—The conductivity of the solvent was in all cases subtracted from the observed conductivity in order to obtain the conductivity due to the dissolved salt. The correction never amounted to more than 4%, and satisfactory agreement between the values for the conductivity of the dissolved salt was obtained even when the conductivity of the pure solvent varied by 100%, provided it did not exceed $1{\cdot}0 \times 10^{-7}$ mho.

Since the viscosity of an $N/100$-silver nitrate solution was the same as that of the pure solvent, it was unnecessary to apply a viscosity correction.

The molecular weights of the salts concerned have been taken as: potassium iodide 166·02; sodium iodide 149·92; lithium iodide 133·86; lithium bromide 86·86; silver nitrate 169·89.

Purification of Materials.—Benzonitrile. Benzonitrile (B.D.H.) was steam-distilled to remove the slight amount of carbylamine present. The distillate was washed with sodium carbonate to remove any benzoic acid, the benzonitrile extracted with ether, and the extract washed with water and dried over calcium chloride. After filtering, the ether was distilled off and the residue distilled under low pressure. The large middle fraction, b. p. 81°/22 mm., was then subjected to the following operations, being redistilled under diminished pressure after each: (1) shaken slowly with a mixture of anhydrous potassium carbonate and calcium chloride and filtered; (2) shaken very slowly with calcium chloride and decanted; (3) left over calcium chloride for some days and decanted. The benzonitrile then had a specific conductivity of $0{\cdot}5 \times 10^{-8}$ mho at 25°. Between two series of measurements it was treated as above, except that the steam-distillation was omitted. The

distilling apparatus was washed with redistilled absolute alcohol and dried in the same way as the flasks used in making up the solutions.

Potassium and sodium iodides. The A.R. quality salts were recrystallised from conductivity water in a platinum basin and dried. Finally they were powdered in an agate mortar and electrically heated in a vacuum to 100° over phosphoric oxide, the drying agent remaining at room temperature. Analysis of the potassium iodide gave 76·4% iodine (calc., 76·4%), and of the sodium iodide 84·6% (calc., 84·7%). The sodium iodide did not turn at all yellow on keeping.

Lithium iodide. A sample of Kahlbaum's lithium iodide was slightly pink and contained free alkali. It was evaporated to dryness with freshly prepared hydriodic acid at about 50° in an electrically heated beaker in a desiccator containing caustic potash, and then recrystallised thrice from redistilled absolute alcohol.* It was perfectly colourless, gave no blue colour with starch, and its aqueous solution was neutral. The salt was dried by heating in a small hard-glass weighing bottle to 120° in the apparatus used for drying the potassium and sodium iodides and evacuating continuously for a week. In order to avoid transference of the very hygroscopic anhydrous lithium iodide, the weighing bottle was weighed empty, and the requisite amount of the damp salt added and dried as described above. The cap of the weighing bottle was then dropped on to it with a pair of forceps as it stood in the desiccator, and the covered bottle was removed, weighed, and dropped into a weighed quantity of pure benzonitrile to make up the stock solution. The material so prepared gave 94·7% iodine (calc., 94·8%), and contained no detectable alkali or free iodine.

Lithium bromide. The B.D.H. product, which was quite colourless and free from alkali, was recrystallised three times from redistilled absolute alcohol, and dried in the same way as the lithium iodide (Found: Br, 92·2. Calc., Br, 92·0%).

Silver nitrate. This was kindly provided by Dr. H. F. Harwood and had been purified for atomic-weight purposes. It was dried in the same way as the potassium iodide.

Alcohol. The absolute alcohol used for washing was redistilled in order to remove any electrolytic or high-boiling impurities.

Results.

The results of the conductivity measurements are given in Table I, v denoting the dilution (in litres). In the column headed Δ

* Since lithium iodide is very soluble in alcohol, recrystallisation from this solvent is wasteful, and an attempt was made to precipitate it by the addition of ether, in which it is insoluble; but the liquid separated into two phases, one chiefly ether and the other a solution of lithium iodide in alcohol.

are the differences between the observed points and a smooth curve drawn through them on a Λ–log c graph. Since the equation of this smooth curve is, except for the most concentrated solutions and for lithium bromide and silver nitrate, $\Lambda_0 = \Lambda + ac^n$, a and n being determined by Ferguson and Vogel's method (*Phil. Mag.*, 1925, **1**, 971), these differences are also the differences between the

observed values and those calculated from this equation. Under Δ' are the differences between the observed points and a straight line drawn through them on a plot of Λ against $\sqrt{c}$, a positive sign before Δ indicating that the observed point is above the curve.

The values of the equivalent conductivity at even dilutions are given in Table II. Interpolation was carried out on a Λ–log c graph drawn with a flexible spline.

Viscosity Measurements.—An Ostwald viscometer was used. The measurements were made in a glass-sided thermostat, the temperature of which was constant to $\pm$ 0·01°. Drying tubes, attached to both ends of the viscometer, were found to be without effect on the time of flow. The viscometer was cleaned with alcohol and nitric acid, washed with water and alcohol, and dried in a warm bath by a current of purified dry air which was filtered from all dust particles by means of a Jena-glass filter. All the wash liquids and liquids to be measured were filtered similarly, since this method for removing dust motes has been found to be both convenient and very efficient. The time of flow was never less than 300 seconds,

and readings were reproducible to $\frac{2}{5}$ sec. after emptying, cleaning, drying, and refilling the viscometer.

A correction was applied for the error at higher temperatures, arising from the fact that the coefficient of expansion of benzonitrile is greater than that of water, and hence that, whilst the volumes of benzonitrile and water placed in the viscometer were equal at the temperature at which they were measured, *viz.*, room temperature, they were not equal at other temperatures. The extra time of flow at 40° due to an additional 1 c.c. of water was determined, and, the effect of 1 c.c. of a liquid of a certain density being known, the effect of any volume of a liquid of any density could be calculated by simple proportion. The difference in volume of the benzonitrile and water in the viscometer was calculated from a knowledge of their densities at the temperatures involved, and the extra time of flow due to the larger volume of the benzonitrile was subtracted from its observed time of flow. The correction never amounted to more than 0·75% and averaged about 0·25%. The viscometer had previously been found by H. B. Oakley, of this department, to have a negligible deviation from Poiseuille's law. The values adopted for the viscosity of water were those of Bingham and White (1912).

The results obtained for the viscosity of benzonitrile at various temperatures were:

Temp.	0°	25°	40°	50°	55°	70°
$\eta \times 10^4$	194	124	100	87·6	82·6	66·6

Extrapolation to Λ_0.—Of the numerous formulæ that have been proposed for extrapolation to the equivalent conductivity at zero concentration (Λ_0) only two need now be considered.

(1) Kohlrausch's square-root law

$$\Lambda_0 = \Lambda + xc^{1/2} \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

is important since it has been theoretically deduced by Debye and Hückel. The accuracy with which it applies to these benzonitrile solutions is illustrated by the differences in the last column of Table I. The range of dilution over which this equation holds is for potassium iodide $N/1000$ to $N/10{,}000$; for sodium iodide up to a concentration of $N/1000$; for lithium iodide up to $N/500$; and for lithium bromide and silver nitrate up to $N/2000$. This range is the same at all the temperatures at which experiments were carried out. In the case of potassium iodide at dilutions greater than 10,000 litres there is a definite deviation which may be due to experimental error. The values of Λ_0 and x obtained by this method are given in Table III, the unit of concentration being 1 g.-equiv. per litre.

TABLE III.

(2) Ferguson and Vogel's formula (*loc. cit.*)

$$\Lambda_0 = \Lambda + ac^n \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

where the best values of the constants a and n are determined by a graphical method, is logically the most satisfactory method of extrapolation. It has been applied except in the cases of silver nitrate and lithium bromide, where an equation of this form is not followed over a wide enough range to permit a satisfactory determination of a and n. In determining the constants in equation (2) the values of Λ at the series of concentrations (c) in geometrical progression were read off from plots of Λ against $\log c$, instead of c, the latter being Ferguson and Vogel's practice. A common ratio of 1·5 was used. The range of concentration over which equation (2) is followed is for potassium iodide from the lowest concentrations measured up to $N/2000$, and for sodium and lithium iodides up to $N/1000$. The values of Λ_0 obtained from equation (2) and the values of the constants a and n are given in Table IV.

TABLE IV.

(Ferguson's method.)

	Values of n.			Values of a.

40	63·83	—	—	0·615	—	—	723·6	—	—
50	—	66·79	64·38	—	0·687	0·711	—	1107	1397
55	76·73	—	—	0·626	—	—	978·4	—	—
70	89·98	82·34		0·631	0·726		1244	1805	—

The values to which both a and n appear to tend with increase of temperature for the iodides of the alkali metals are in the inverse order of atomic weight. At the lower temperatures there is no regularity, and that at the higher temperatures is perhaps merely fortuitous. This is in contrast with the finding of Ferguson and Vogel (*loc. cit.*, 1925) for electrolytes in water.

Discussion.

The Values of Λ_0.—For the iodides of the alkali metals Λ_0 increases with increasing atomic weight and volume. Frazer and Hartley (*loc. cit.*) observed the same phenomenon in methyl-alcoholic solutions. It must, therefore, be supposed that solvation or some form of interaction between solvent and solute occurs in these solvents as well as in water.

In Table V are given the ratios of the values of Λ_0 for the salts in benzonitrile at 25° to the corresponding values in water and methyl alcohol at 25°, and for potassium iodide at 0°, 25°, 40°, 55°, and 70° in benzonitrile to the values at the corresponding temperatures in nitromethane. The values in aqueous solution were obtained from the data of Kohlrausch ("Das Leitvermögen der Elektrolyte," 1916), in nitromethane from those of Philip and Oakley (*loc. cit.*), and in methyl alcohol from those of Frazer and Hartley (*loc. cit.*). In the last case, the values of Λ_0 of lithium iodide, lithium bromide, and sodium iodide were calculated from the ionic mobilities concerned, these salts not having been directly investigated. For the sake of consistency values of Λ_0 determined by the square-root law have been used throughout. The ratios of the viscosities of the solvents are also given.

If the motion of the ions is in accordance with Stokes's law, and if the ions are the same size in each solvent, the ratio of the values of Λ_0 of a given salt in two solvents should equal the ratio of the fluidities (*i.e.*, the inverse ratio of the viscosities) of the solvents. This is so for benzonitrile and methyl alcohol, and approximately so for benzonitrile and nitromethane, but for benzonitrile and water the values of Λ in the former are about half as great as would be

expected from its viscosity. This can be explained by supposing that in the two non-aqueous solvents the extent of solvation or interaction between ion and solvent as suggested by Born (*Z. Physik*, 1920, **1**, 221) is the same, and in both cases greater than in water. That in this respect benzonitrile resembles methyl alcohol and that both differ from water affords yet further evidence of the unique position of water amongst liquids.

The Variation of Λ_0 *with Temperature.*—If the logarithm of Λ_0 for a given salt at different temperatures is plotted against the logarithm of the fluidity of the solvent, an unequivocally straight line results, from the slope of which it is found that Λ_0 varies as the mth power of the fluidity, where m for potassium iodide is 1·01, for sodium iodide 0·99, for lithium iodide 1·00, for lithium bromide 0·97, and for silver nitrate 1·01. It is clear that within the limits of experimental error Λ_0 is directly proportional to the fluidity of the solvent, and the constancy of the product $\Lambda_0\eta$ for a given salt is clearly shown in Table VI, which gives values of Λ_0 at 10° intervals from 0° to 70°, and of the product $(\Lambda_0)_t.\eta_t$. The values of Λ_0 and η at temperatures at which they were not measured were interpolated graphically from plots of these quantities against temperature. Deviations from simple proportionality occur for all electrolytes at 60° and 70°.

Comparison of the Results with the Theory of Debye and Hückel.

According to the theory of Debye and Hückel (*Physikal. Z.*, 1923, **24**, 305) there is, in dilute solutions of strong electrolytes, a linear relation between equivalent conductivity and the square root of the concentration. The author's results (with the exception of those for extremely dilute potassium iodide solutions, which may be in error) are in agreement with this theory in so far as they yield straight-line plots of Λ against $\sqrt{c}$, as demonstrated by the fact that there are as many positive as negative differences in the last column of Table I; but the agreement with the equation $\Lambda_0 = \Lambda + ac^n$, where n is not 0·5, is still closer, as is evident from

a comparison of the last two columns of Table I. However, the mean differences from the square-root law (1 part in 400 parts) and from equation (2) (1 part in 1000 parts) are both near to the possible accidental error of the measurements, and in addition there is the possibility of a slight systematic error, the magnitude of which could not be estimated from the data themselves. The true value of the index n therefore remains in doubt, for the somewhat superior fit of equation (2), in which there is an additional adjustable constant, may represent not a law of nature but merely the experimental error of the measurements. A comparison of the ranges of concentration over which the rival equations hold leads to no conclusion, since this range is approximately the same for both and the square-root law, according to Debye's theory, cannot be expected to hold in concentrated solutions owing to the approximations made in its deduction. At this point exception must be taken to Ferguson and Vogel's practice of testing the fit of their equation by comparing the consistency of the values of Λ_0 calculated from it with that of those calculated from the square-root law, using in both cases rounded values of Λ read off from a plot of Λ against c, *i.e.*, from the curve whose equation is $\Lambda_0 = \Lambda + ac^n$. The consistency of the values of Λ_0 so determined from their equation is a measure, not of its agreement with experiment, but of the skill with which a curve of the form $\Lambda_0 = \Lambda + ac^n$ has been drawn and its constants determined. Equation (2) is therefore represented in an unduly favourable light.

A similar situation occurs in methyl-alcoholic solutions, and here the view that the deviation of n from 0·5 is due to experimental error is favoured by the fact that the values of Λ_0 calculated from equation (2) definitely do not agree with Kohlrausch's law of the independent migration of ions, the validity of which can hardly be doubted, as closely as those calculated from the square-root law (Frazer and Hartley, *loc. cit.*; Vogel, *Phil. Mag.*, 1928, 5, 199). On the other hand, it is difficult to believe that, although in general the values of n are within 20% of 0·5, this deviation, in aqueous as well as in non-aqueous solution, is in every case due to experimental error. Furthermore, certain regularities have been found in the author's data, based on values of Λ_0 calculated from equation (2), which do not always occur if those yielded by the square-root law are used (see later).

The author inclines to the opinion that deviations from the square-root law are magnified when judged by the difference between the value of n in equation (2) and 0·5, but that when this difference is large and the data are accurate there is a departure from the theory of Debye and Hückel. From the foregoing, the

inadequacy both of plotting Λ against $\sqrt{c}$ and of determining n in equation (2) as a test of Debye's theory is apparent, and as a more certain test the slope of the Λ–$\sqrt{c}$ line and its calculation from the theory will now be considered.

The original Debye–Hückel theory (*loc. cit.*, p. 315) gives the following derivation for the slope (x) of the straight line obtained by plotting Λ against $\sqrt{c}$ for uni-univalent electrolytes:

$$1 - f_\Lambda = (\Lambda_0 - \Lambda)/\Lambda_0 = (K_1 w_1 + K_2 b)\sqrt{2c} \quad . \quad . \quad (3)$$

$$K_1 = \frac{\varepsilon F}{6DRT}\sqrt{\frac{4\pi F^2}{DRT \times 10^3}}; \qquad K_2 = \sqrt{\frac{4\pi F^2}{DRT \times 10^3}}$$

where ε = the elementary charge of electricity;
D = the dielectric constant of the solvent at $T°$ (Abs.);
F = the value of the faraday ($= N\varepsilon$, where N = Avogadro's number);
R = the gas constant per g.-mol.;
$w_1 = \frac{1}{2}(l_a/l_c + l_c/l_a)$, where l_a and l_c are the mobilities of the anion and kation, respectively;
and b = the mean radius of the anion and kation.

(The term $K_1 w_1$ gives the diminution in conductivity due to the dissymmetry of the ion atmosphere, and the term $K_2 b$ that due to electrophoresis and the viscous drag of the solvent.)

Writing $\Lambda_0 = \Lambda + x\sqrt{c}$, we have

$$1 - f_\Lambda = x\sqrt{c}/\Lambda_0 = x\sqrt{2c}/\Lambda_0\sqrt{2},$$

and combining this with equation (3), we obtain

$$b \times 10^8 = (x/\Lambda_0\sqrt{2} - K_1 w_1)/K_2 \times 10^{-8}. \quad . \quad . \quad (4)$$

Since b is unknown, Debye prefers to put his equation in this form, and to show that the values of b so determined are not inconsistent with our knowledge of their order of magnitude. The dielectric constant of benzonitrile has been taken as 26 at 25°. The mobilities of the anion and kation were obtained by the use of Kohlrausch's law of the independent migration of ions, and of the assumption that the mobility of the tetraethylammonium ion is given by the relation (Ulich, *Fortschritte d. Chemie*, 1926, **18**, No. 10; *Trans. Faraday Soc.*, 1927, **23**, 388)

$$\text{mobility} \times \text{viscosity of solvent} = 0{\cdot}295 \quad . \quad . \quad (5)$$

For tetraethylammonium iodide Λ_0 was obtained by extrapolating Walden's data (*Z. physikal. Chem.*, 1906, **54**, 189) by the square-root law. Values of the ionic mobilities thus obtained cannot be regarded as very trustworthy, but since l_a is approximately equal

to l_c the term $\frac{1}{2}(l_a/l_c + l_c/l_a)$ is not sensitive to changes in l_a and l_c. For silver nitrate, the ionic mobilities were obtained from Koch's measurements of the *E.M.F.* of silver nitrate concentration cells in benzonitrile (this vol., p. 524). The approximate values of the ionic mobilities are: $N(C_2H_5)_4^{\cdot}$ 23·8, I′ 29·5, Br′ 18·4, NO'_3 27·9, $Li^{\cdot}$ 17·8, $Na^{\cdot}$ 18·6, $K^{\cdot}$ 22·6, $Ag^{\cdot}$ 24·3.

Inserting numerical values for benzonitrile at 25° in equation (4), we have

$$b \times 10^8 = (x/\sqrt{2}\Lambda_0 - 1{\cdot}439w_1)/0{\cdot}4035 \quad . \quad . \quad . \quad (6)$$

The values of Λ_0 used in calculating b from equation (6) are those obtained by extrapolation by the square-root law. Table VII gives the result of this calculation together with values of b calculated from the respective ionic mobilities on the assumption (1) that the only resistance to the motion of the ions at infinite dilution is the viscous drag of the solvent, and (2) that the magnitude of this drag is given by Stokes's law. This assumption is probably not strictly justified; however, a similar error occurs in equations (3), (4), and (6) since Debye (*Trans. Faraday Soc.*, 1927, **23**, 334) treats the term K_2b as being made up of two parts—one given by Stokes's law, and the other due to the fact that an external force acts on the elements of volume of the liquid (electrophoresis). For comparative purposes this error may therefore be neglected as a first approximation.

TABLE VII.

Values of the Mean Ionic Radius (b) *at 25° calculated from Debye and Hückel's Theory.*

Electrolyte.	$b \times 10^8$ (Debye and Huckel), cm.	$b \times 10^8$ (from ionic mobilities at infinite dilution and Stokes's law), cm.
KI	5·16	2·57
NaI	3·72	2·88
LiI	6·47	2·96
LiBr	32·4	3·63
$AgNO_3$	29·9	2·58

The following points may be noted: (1) The values of the mean ionic radii calculated from Debye and Hückel's theory are, except for lithium bromide and silver nitrate, of the correct order of magnitude. They are somewhat larger than in water and methyl alcohol. (2) Frazer and Hartley (*loc. cit.*) found a similar exceptionally large value of b for silver nitrate in methyl alcohol. Were it not for the fact that the value calculated from the ionic mobilities and Stokes's law is not large, one would be tempted to ascribe this large value to solvation and to link it up with the very great solubility of silver nitrate in benzonitrile. (3) For lithium iodide b is larger than for sodium iodide, but potassium iodide occupies an intermediate

position; yet the values of b calculated from the ionic mobilities and Stokes's law are in the usual inverse order of atomic weight: $Li^{\cdot} > Na^{\cdot} > K^{\cdot}$.

That only the order of magnitude of b and not its exact value is known independently of the theory renders this test much less convincing.

Onsager's Modification of the Debye–Hückel Theory.—Onsager (*Physikal. Z.*, 1926, **27**, 388; 1927, **28**, 277) has recently introduced a refinement into the Debye–Hückel theory by taking into account the Brownian movement of the ions. The final expression at which he arrives does not contain b, and does not require a knowledge of the individual ionic mobilities; when the numerical values of universal constants are inserted, it is, for uni-univalent electrolytes,

$$\Lambda = \Lambda_0 - \left[\frac{5{\cdot}78 \times 10^5}{(DT)^{3/2}}\Lambda_0 + \frac{58{\cdot}0}{(DT)^{1/2}\eta}\right]\sqrt{2c} \quad . \quad . \quad (7)$$

For benzonitrile at 25° this becomes

$$\Lambda = \Lambda_0 - (0{\cdot}8475\Lambda_0 + 53{\cdot}14)\sqrt{2c} \, . \quad . \quad . \quad . \quad . \quad (8)$$

The great merit of equations (7) and (8) is that they contain no adjustable constants, and therefore provide a good test for the theory on which they are based. In the following table the slopes of the Λ–$\sqrt{c}$ lines calculated from equation (8) are given under "x, calc.," and the observed values under "x, obs." The values of Λ_0 used are those calculated by the square-root law, since according to equation (8) the law should hold: the use of values of Λ_0 determined by equation (2) makes very little difference.

Electrolyte.	KI.	NaI.	LiI.	LiBr.	$AgNO_3$.
x, calc.	137·5	132·9	131·9	118·5	137·8
x, obs.	263·3	210·0	283·6	744·5	998·3

For the three iodides the observed slope is about twice as great as the calculated, and for lithium bromide and silver nitrate some 7—8 times. The differences between the observed slopes for the various electrolytes are greater than those between the calculated slopes. It should be mentioned that the agreement of theory with observation is quite good in aqueous and methyl-alcoholic solutions.

Incomplete Dissociation and Applicability of the Law of Mass Action to the Dissociation of Strong Electrolytes.—Bjerrum (*Kgl. Danske Videnskap. Selsk. math.-fys. Medd.*, 1926, VII, 9) suggested that, in concentrated solutions of strong electrolytes, association of ions into electrically neutral doublets occurs. This is the factor which Onsager (*Physikal. Z.*, 1927, **28**, 277) considers accounts for a Λ–$\sqrt{c}$ slope greater than the theoretical. He writes, as an approximation,

$$\Lambda = \Lambda_0 - x\sqrt{c} - \Lambda_0 c/K,$$

where K is the dissociation constant of the electrolyte. However, he states that the mode of ionic association cannot be determined from the conductivity curve, and suggests an investigation of the viscosity and optical properties of the solution. He gives values for the dissociation constants of potassium and thallium nitrates and thallium chloride in water at one concentration only, calculated by comparing the values of Λ for these salts with that of potassium chloride at the same concentration, the last salt being assumed to be completely dissociated.

Fajans (*Trans. Faraday Soc.*, 1927, **23**, 357) has found evidence for the existence of undissociated molecules in concentrated solutions from refractometric data, but the concentrations at which he worked are so great that his results can hardly be said to conflict with the postulates of the Debye–Hückel theory.

Nernst (*Z. Elektrochem.*, 1927, **33**, 428) satisfactorily accounted for the heats of dilution of strong electrolytes in water, one of the most outstanding failures of the Debye–Hückel theory, by assuming incomplete dissociation governed by the law of mass action in addition to the effects due to the Debye–Hückel interionic attraction. He has recently shown (*Sitzungsber. Preuss. Akad. Wiss. Berlin*, 1928, 4) that, if the greater decrease in equivalent conductivity with increasing concentration of certain electrolytes in water compared with that of potassium iodide and bromide be assumed to be due to incomplete dissociation, values of the degree of dissociation are obtained in approximate agreement with those calculated from the freezing-point depression, the effect of the interionic attraction being taken into account in this latter calculation.

It appears to the author that the law of mass action should be applicable to electrolytic dissociation if there is a sharp distinction between the type of interaction represented by an electrically neutral doublet (undissociated molecule) and that represented by an ion atmosphere of opposite sign surrounding a given ion (the interaction taken account of by the Debye–Hückel theory). The true degree of dissociation (α) is not given by the ratio Λ/Λ_0, since in this expression the decrease in conductivity due to the Coulomb forces between the ions (Debye effect) is not taken into account, and α has, therefore, been evaluated in the following way.

A graph was made of the theoretical relation between Λ and $\sqrt{c}$ deduced from Onsager's expression (8), using values of Λ_0 determined by equation (2). From this graph values of Λ (calculated) at a series of concentrations (c) were read off. The values of Λ (observed) used were those at round concentrations obtained from a plot of Λ against $\log c$. The ratio Λ (obs.)/Λ (calc.), at a given concentration c, gave the first approximation (α_1) to α. From

this value of α_1, the concentration of ions $\alpha_1 c (= c')$ which was responsible for the observed conductivity was calculated. The ratio $\frac{\Lambda, \text{ calculated for an ionic concentration } c}{\Lambda, \text{ calculated for an ionic concentration } c'}$ gave the second stage (α_2) in the approximation to α. If the point having the co-ordinates Λ (obs.; total conc. $= c)/\alpha_1\alpha_2$ and $\sqrt{\alpha_2 c'}$ lay within the limits of experimental error on the theoretical Λ–$\sqrt{c}$ straight line, this method of successive approximation was not carried further. The degree of dissociation (α) at concentration c was then given by $\alpha_1\alpha_2$. In very dilute solutions one approximation was sufficient and only very rarely were more than two necessary. Although the theoretical slope is only slightly altered if values of Λ_0 determined by the square-root law instead of by equation (2) are used, considerably different values of α would be obtained for very dilute solutions, since in this region the differences between the theoretical and observed values are of the same order of magnitude as the differences in the intercepts on the axis of $\Lambda(\Lambda_0)$.

The results of this calculation are given in Table VIII, together with the values of the Ostwald dilution-law constant, $K = \alpha^2/(1-\alpha)v$, calculated from the values of α determined as above. In the cases of silver nitrate and lithium bromide, the theoretical values were calculated from the values of Λ_0 given by the square-root law, since it was impossible to apply equation (2) to these salts. The error caused by so doing is not large because the differences between the observed and calculated values of Λ are much greater for these salts than for the iodides of the alkali metals.

* $100\alpha = 100$ at $v = 50{,}000$.

When allowance is made for the fact that in extremely dilute solutions α is so nearly 100% that a small error in it results in a relatively large error in $1 - \alpha$, and consequently in K, the constancy of K can be regarded as established.

By the foregoing method we have determined $K = c_i{+}c_i{-}/c$, where $c_i{+}$ and $c_i{-}$ are the concentrations of positive and negative ions and c is that of undissociated molecules. But strictly it is the expression $K' = \gamma_+ c_i{+}\gamma_- c_i{-}/\gamma_\mu c$, where the γ's are the respective activity coefficients, that should hold if the law of mass action applied to the equilibrium between ions and undissociated molecules. Since the activity coefficients involved have not been measured, γ_+ and γ_-, each of which for a uni-univalent electrolyte equals $\gamma_\pm$, have been calculated from the Debye–Hückel theory, and γ_μ has been assumed to be unity at all concentrations. This assumption is not strictly correct, but it is probable that the change in γ_μ with concentration is small compared with that in $\gamma_\pm$, and since γ_μ cannot be calculated, some assumption must be made about it. The equation of Debye and Hückel for the activity coefficient (*Physikal. Z.*, 1923, **24**, 185) is, for a uni-univalent electrolyte,

$$-\log_e \gamma_\pm = \frac{\varepsilon^2}{2DkT}\sqrt{\frac{4\pi\varepsilon^2}{DkT}\Sigma n_i} - \frac{2\pi\varepsilon^4 a}{(DkT)^2}\Sigma n_i \quad . \quad (9)$$

where k = Boltzmann's gas constant, n_i = the number of ions of the ith kind per c.c. of solution, a = the mean ionic diameter (taken as 6×10^{-8} cm.), and the other symbols are as already defined.

For benzonitrile at 25°, equation (9) becomes

$$-\log_{10} \gamma_\pm = 2{\cdot}66\sqrt{c} - 9{\cdot}12c \quad . \quad . \quad . \quad . \quad (10)$$

Table IX gives the values of the constant $K'(\times 10^3)$.

TABLE IX.

Electrolyte.	Dilution (litres). 20,000	10,000	5,000	2,000	1,000	500	100	Mean.
KI	16	13	11	9	9	—	—	11
NaI	20	17	14	13	14	12	—	14
LiI	—	11	9	8	7	6	8	8
LiBr	—	0·35	0·36	0·33	0·27	0·27	—	0·32
$AgNO_3$	0·31	0·36	0·40	0·40	0·40	0·41	0·41	0·40

The constancy of K' is approximately the same as that of K, and in the case of silver nitrate it is much greater. We may therefore say that the whole of the conductivity–concentration curve can be described by a dissociation governed by the law of mass action, the mobility of the resulting ions varying with their concentration, owing to the Coulomb forces between them, in the manner predicted by the Debye–Hückel–Onsager theory. In extremely dilute solu-

tions dissociation is complete and the change in conductivity with concentration is determined entirely by the Coulomb forces between the ions.

The use of values of Λ_0 obtained from equation (2) in the foregoing calculation is justified since in this way the limiting value of the conductivity at zero concentration is found, no matter how many factors influence the variation of Λ with concentration and without any prejudices as to the nature of these factors, whereas the square-root law can be expected to give a correct result only when the sole factor influencing it is the Coulomb forces between the ions. That this regularity is found by the use of values of Λ_0 determined by equation (2) and not (in some cases) by using those given by the square-root law, indicates that here the deviation of the index n from 0·5 is not due merely to experimental error.

For the sake of comparison the following table is given, which contains values of $\alpha = \Lambda/\Lambda_0$ [Λ_0 being obtained from equation (2)] and the corresponding values of K for sodium iodide at 25°. To apply an activity correction to these values of K is illogical, since if the effect of interionic attraction is neglected in calculating α, it should also be neglected in calculating K. It is seen that K is definitely not constant.

v (litres)	50,000	20,000	10,000	5,000	2,000	1,000	500
100α	98·72	97·84	96·72	94·96	91·34	87·05	80·24
$1000K$	1·5	2·2	2·8	3·6	4·7	5·8	6·5

Summary.

1. The conductivities of the iodides of lithium, sodium, and potassium, of lithium bromide, and of silver nitrate in benzonitrile have been measured over a range of dilution of from $N/500$ to $N/10{,}000$ or $N/50{,}000$, and over a range of temperature of from 0° to 70°.

2. The viscosity of benzonitrile over the same range of temperature has been measured.

3. Extrapolation to Λ_0 has been carried out by the square-root law and by Ferguson's method. The merits of the latter method have been discussed.

4. Over almost the whole range of temperature Λ_0 is directly proportional to the fluidity of the solvent.

5. The values of Λ_0 for a given salt have been compared with the values of Λ_0 for the same salt in aqueous, methyl-alcoholic, and nitromethane solution.

6. The slopes of the Λ–$\sqrt{c}$ straight lines are approximately twice as great as those calculated from the Debye–Hückel–Onsager theory.

7. The whole of the conductivity–concentration curve can be

described by a dissociation governed by the law of mass action, the mobility of the resulting ions varying with their concentration owing to the Coulomb forces between them, in the manner predicted by the Debye–Hückel–Onsager theory. In extremely dilute solutions dissociation is complete.

In conclusion, the author wishes to express his warmest thanks to Professor J. C. Philip, F.R.S., for suggesting this subject for research, and for his lively interest in the work. Acknowledgments are also due to the Department of Scientific and Industrial Research for a maintenance grant and to the Dorset County Council for a Senior County Scholarship.

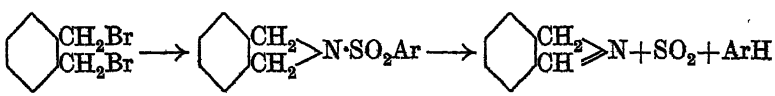
NOTES.

A Gas Circulating Pump. By Guy Barr.

A large number of pumps for the circulation of gas through a closed system have been described in the literature, the intermittent motive power being supplied by an electrical solenoid, a motor, a vacuum pump, etc. The form which is the subject of this note is actuated by water pressure and appears to be capable of many applications in physico-chemical work. An earlier design was inspired by the apparatus described by Maass (*J. Amer. Chem. Soc.*, 1919, **41**, 53), which is operated by a filter-pump; the consumption of water was, however, reduced to little more than the volume of gas moved, by making a direct connexion to the water-main at T and allowing the water to run to waste through tap 2 (Fig. 1, *loc. cit.*). A pump was assembled, on these lines, so as to vary the height of the mercury by some 2 inches only and has been found to be quite satisfactory in operation when a circulation of gas up to about 50 c.c. per minute against a negligible resistance is required. A few simplifications appeared possible and these were incorporated in a second pump which has been constructed to work against heads of several inches of water for some experiments requiring the gas to be circulated through wash-bottles.

At A (see fig.) water from the mains enters a vertical tube, R, at the bottom of which there is an amount of mercury sufficient to fill the narrow tube B when displaced into it. (The bore of B must not be more than about 3·5 mm.) Water flows at the same time into the outer tube of C, which is half full of mercury, and as the pressure rises, this mercury is pushed up the inner tube of C.

The pressure increases until the column of mercury in B is, fairly suddenly, blown out into D; water is then free to escape through B and D to the exit E, so that the pressure in C is released and the "piston" of mercury in the inner tube of C falls. At the beginning of the cycle the U-tube F, connecting R and D, is full of mercury to about the level GG: during the rise of pressure this mercury is of course moved towards D and at the moment of release of pressure the mercury from B is added to the top of the column in D. When the pressure in R and C has fallen sufficiently owing to the escape of water through B, mercury from D siphons over into R through the small tube H at the top of F, and seals B once more. The cycle is then repeated. The figure shows the positions of the mercury levels at a certain stage during the up-stroke of the "piston."



The liquid non-return valves or wash-bottles K, L operate in the usual manner, gas being bubbled through K as the mercury rises in the inner tube of C and sucked through L as it falls. The bottles are detachable for convenience, mercury seals providing a gas-tight connexion with the rest of the apparatus: the washing liquid may therefore be analysed if required. (Alternatively the bottles may be fused on, in which case a tap at the bottom is desirable for addition or removal of the liquid.) Connexion with the apparatus in which gas is to be circulated is made at M and N, the taps below being used for admission and removal of gas. Other stop-cocks are provided for release of air from the water supply, for adjustment of the quantities of mercury in C and F, and for regulation of the rate of fall of the mercury from D during the "blow-off" period. Constriction of the lower end of the inner tube of C would tend to equalise the suction and delivery speeds. The mean position of the mercury in C, and hence the mean pressure in the system beyond M and N, may be varied during an experiment, not only by manipulation of the appropriate taps, but also by adjustment of the position of the discharge end of a piece of rubber tubing attached to E.

The apparatus will circulate up to 100 c.c. of gas per minute against a head of an inch of water, using approximately the same volume of water per minute. Against higher heads the rate of circulation is diminished by wasteful compression in the dead space above the mercury piston. The principle involved may obviously be applied to many other purposes, *e.g.*, to the lifting of mercury in Sprengel or Töpler pumps if sufficient water pressure is available and suitable precautions are taken to prevent the mercury from retaining water.—NATIONAL PHYSICAL LABORATORY. *An Attempt to Prepare ψ-iso*Indole. By GEOFFREY WILLIAM FENTON and CHRISTOPHER KELK INGOLD.

HOLMES and INGOLD having discovered (J., 1926, 1305) that the aromatic sulphonyl derivatives of benzylamine bases, on treatment with concentrated alkalis, yield the corresponding benzylideneimines, sulphur dioxide, and the appropriate aromatic hydrocarbons, we attempted to exploit this novel reaction for the preparation of *ψ-iso*indole, several more conventional methods of synthesis having already failed to yield this compound. The proposed scheme was as follows :

o-Xylylene dibromide (26·4 g.) was added to a cold suspension of *p*-toluenesulphonamide (17·0 g.) and anhydrous sodium carbonate (10 g.) in a solution of sodium ethoxide (sodium, 4·5 g.) in ethyl alcohol (150 c.c.). The mixture was gently warmed, then boiled for 2 hours, cooled, mixed with water, and nearly neutralised with acetic acid. The precipitated solid contained some unchanged *p*-toluenesulphonamide, which was removed by crystallisation from alcohol; 2-p-*toluenesulphonyldihydroisoindole* was then obtained (13 g.) as prisms, m. p. 176° (Found : C, 65·8; H, 5·65. $C_{15}H_{15}O_2NS$ requires C, 65·9; H, 5·5%). The 2-*benzenesulphonyl* derivative, prepared similarly, formed needles, m. p. 140° (Found : C, 64·6; H, 5·3. $C_{14}H_{13}O_2NS$ requires C, 64·9; H, 5·0%).

The *p*-toluenesulphonyl compound, on distillation in an atmosphere of nitrogen with concentrated aqueous potassium hydroxide (optimum concentration, 85%; range investigated, 70—near 100%), gave a distillate consisting of toluene and, in small yield, a basic product; and sulphite, but not *p*-cresol, was identified in the alkaline residue, which also contained some tar. The *picrate* of the base separated from alcohol in greenish-yellow leaflets, m. p. 196—197°

(decomp.) after discoloration from about 175°. Analysis indicated that this was the picrate, not of *ψ-iso*indole, but of dihydro*iso*indole (Found: C, 48·8, 48·8, 48·8, 48·6; H, 3·68, 3·69, 3·73, 3·51; N, 16·12, 16·08. $C_{14}H_{10}O_7N_4$ requires C, 48·5; H, 2·91; N, 16·19%. $C_{14}H_{12}O_7N_4$ requires C, 48·3; H, 3·45; N, 16·10%). The benzenesulphonyl derivative, on corresponding treatment, gave a closely similar picrate, m. p. 195—198° (decomp.) with previous discoloration (Found: C, 48·4, 48·4; H, 3·58, 3·30; N, 16·24, 15·97%). Both preparations were extremely similar to, and almost certainly identical with, the picrate derived from an authentic sample of dihydro*iso*indole prepared as described by v. Braun (*Ber.*, 1922, **55**, 2062).

To obtain confirmation of this remarkable result we turned to the corresponding 1-methyl homologues, since in this case methods for the production of both the *ψ-iso*indole and its dihydro-derivative have been reported (Gabriel and Neumann, *Ber.*, 1893, **26**, 705). The picrate from 1-methyl-*ψ-iso*indole, prepared as described by these authors, decomposed from 135° upwards (Found: C, 50·3; H, 3·7. Calc.: C, 50·0; H, 3·4%). Our specimen of the picrate of the dihydro-derivative had m. p. 151°, and the nitrosoamine had m. p. 100°. By digestion in the cold with an acetone solution of *p*-toluenesulphonyl chloride and 10% sodium hydroxide in aqueous acetone, the dihydro-base was quantitatively converted into 2-p-*toluenesulphonyl*-1-*methyldihydro*iso*indole*, which crystallised from aqueous alcohol in rhombic prisms, m. p. 93° (Found: C, 66·8, 67·0; H, 6·03, 6·32. $C_{16}H_{17}O_2NS$ requires C, 66·8; H, 5·96%).

On distilling this substance in nitrogen with potassium hydroxide (optimum concentration, 75%; range investigated, 70— near 100%), toluene, sulphite, a volatile base, and a tar, but no *p*-cresol, were again produced, and in the basic product 1-methyldihydro*iso*indole was definitely identified by the preparation of its nitrosoamine and *p*-toluenesulphonyl derivative.

Hence, although the formation of two of the expected products (SO_2 and ArH) seems to show that the reaction hoped for must occur, the third, namely the *ψ-iso*indole, undergoes extensive reduction during the process. We have not proved that this reduction is complete, and we have not identified the source of the hydrogen. Our general conclusion is that *ψ-iso*indole must be much less stable than indole, and that this difference is connected with the more symmetrical distribution of the three elements of unsaturation in the heterocyclic ring of the latter:  . This indicates that

the aromatic sextuple valency association is essentially peripheral (see Goss and Ingold, this vol., p. 1268).

We wish to thank the Chemical Society for a grant in aid of this investigation.—THE UNIVERSITY, LEEDS. [*Received, October 26th*, 1928.]

Note on the Paper by Hartley and Barrett on "The Determination of the Density of Liquids." * By JOHN GRINDLEY.

Sir Harold Hartley and W. H. Barrett (J., 1911, 99, 1072) have made a careful study of the conditions under which the densities of liquids can be measured with an accuracy of $\pm 0{\cdot}000005$ when relatively small quantities of the liquids are available. The method they recommend seems entirely suitable for determining the densities of dilute aqueous solutions at temperatures differing little from room temperature, to which attention is specially devoted in their paper, but leads to appreciable errors when the densities of liquids having a larger temperature coefficient of expansion are being determined at temperatures differing by five or more degrees from room temperature. They recommend that the pyknometer be weighed against a counterpoise, equal in volume to that of the full pyknometer, and neglect buoyancy corrections except when the pyknometer is weighed empty. This assumes that the full pyknometer, when in the balance case, has a definite volume, whereas its volume depends first on the coefficient of expansion of the liquid it contains, and secondly on the difference between the temperature at which it was filled, *i.e.*, the temperature at which densities are being determined, and that of the balance case. If the pyknometer be first filled with water and then with some more expansible liquid, both say at 0° or 30°, the volume of the full pyknometer in the balance case at room temperature, say 15°, will be different in the two cases and the buoyancy corrections cannot be entirely neglected. It is not essential that the counterpoise be of exactly the same volume as that of the full pyknometer (permissible differences are discussed by Hartley and Barrett), but it is important that the difference between their volumes remains constant throughout a series of experiments. If, for example, a pyknometer of 25 c.c. capacity, whose glass occupies 4 c.c., be filled with water at 0°, its volume at 15° will be 29·018 c.c.; if it be then filled with butyric acid ($d_4^{0°} = 0{\cdot}97844$, $d_4^{15°} = 0{\cdot}96344$) at 0°, its volume at 15° will be 29·390 c.c.

* At the request of Sir Harold Hartley, this opportunity is taken of directing attention to a typographical error in the original paper of Hartley and Barrett. Page 1074, line 13 and heading of first column of the table: for (W_1) read $(W_p - W_c)$.

If the volume of the counterpoise be 29·018 c.c., the buoyancy correction is zero when the pyknometer is full of water; when full of butyric acid, its volume is greater than that of the counterpoise by 0·372 c.c., which (at 760 mm. pressure) leads to a buoyancy correction of 0·00048 gram, sufficient to alter the calculated density by 0·000015.

To correct this error, the formula given by Hartley and Barrett must be modified :—

Let V_w and V_l = the volumes of the water and of the liquid, respectively, in the pyknometer at the temperature of the balance case, δ'_w and δ'_l = the densities of water and of the liquid, respectively, at the temperature of the balance case, and let the other symbols used by Hartley and Barrett have the same significance as before; then, instead of their equation (2), read :

$$(2) \qquad W_2 = W_p + \delta_w V_p - \Delta_2(V_{pg} + V_w) - (W_c - \Delta_2 V_c),$$

and instead of their equation (3) read :

$$(3) \qquad W_3 = W_p + \delta_l V_p - \Delta_3(V_{pg} + V_l) - (W_c - \Delta_3 V_c).$$

Since $\delta_w V_p = \delta'_w V_w$ and $\delta_l V_p = \delta'_l V_l$

and if $V_c = V_{pg} + V_p$,

combination of the above equations (2) and (3) with equation (1) of Hartley and Barrett gives :

$$\delta_l = \delta_w \frac{W_3 - W_1 + \Delta_1(V_c - V_{pg}) + \Delta_3 V_p\left(\frac{\upsilon_l}{\delta'_l} - 1\right.}{W_2 - W_1 + \Delta_1(V_c - V_{pg}) + \Delta_2 V_p\left(\frac{\upsilon_w}{\delta'_w} - 1\right.},$$

which approximates closely to the more convenient expression

$$\delta_l = \delta_w \frac{W_3 - W_1 + \Delta_1(V_c - V_{pg}) + \Delta_3 V_p\left(\frac{\delta_l}{\delta'_l} - \frac{\delta_w}{\delta'_w}\right.}{W_2 - W_1 + \Delta_1(V_c - V_{pg})}$$

As can be seen, the added term $\Delta_3 V_p\left(\frac{\delta_l}{\delta'_l} - \frac{\delta_w}{\delta'_w}\right)$ becomes negligible both when densities are determined at temperatures close to room temperature, *i.e.*, $\delta_l/\delta'_l = \delta_w/\delta'_w = 1$, and when the liquid studied has an expansibility similar to that of water, *i.e.*, $\delta_l/\delta'_l = \delta_w/\delta'_w$, in both of which cases the simpler expression of Hartley and Barrett suffices.

The symbol δ_l in the added term can be evaluated with sufficient accuracy by the simpler equation, and δ'_l can be found by interpolation from the densities determined over a range of temperatures.

OBITUARY NOTICES.

FREDERICK MOLLWO PERKIN.

BORN NOVEMBER 8TH, 1869; DIED MAY 24TH, 1928.

FREDERICK MOLLWO PERKIN, the son of Sir William Perkin by his second marriage, was born at Sudbury, Middlesex, on November 8th, 1869. He was educated at Amersham Hall School, Reading. On leaving school he studied at the Royal College of Science, at Edinburgh University, and also at the Heriot-Watt College, Edinburgh, and finally at the University of Würzburg, where he took the degree of Ph.D., studying chemistry under Professor Hantzsch.

In 1897 he became head of the Chemical Department of the Borough Polytechnic Institute, a position which he resigned in 1909 in order to enter into practice as a consulting chemist. This work he carried on in the laboratory of his late father, Sir William Perkin, at Sudbury, but he also had a laboratory in London, and in addition for some years he carried on a consulting practice in Bradford.

His first paper, "Some Derivatives of Piperonyl," was published in our Journal (1891, **59**, 150). The work done for his doctorate in Würzburg is to be found in the two joint papers with Hantzsch: "Zur Kentniss der Diazoamidoverbindungen" and "Zur Wander ung von Diazogruppen" (*Ber.*, 1897, **30**, 1394 and 1412). In addition to a number of subsidiary investigations, his chief con tributions to chemistry concerned the introduction and elaboration of electrolytic methods for the preparation of organic compounds. Bearing on this, reference may be made to his best-known book, "Practical Methods of Electrochemistry," which was soon recognised as the standard work in English on the subject. The papers describing the results of these investigations were published in part in our Journal, but mainly in the *Transactions* of the Faraday Society.

F. M. Perkin's technical work was concerned largely with the production of fuel oils from coal and from peat, and he was Technical Adviser to the Committee for the Production of Oil from Cannel Coal and Allied Minerals. He worked on the utilisation of peat, and on its conversion into briquettes, on the carbonisation of coal, and the production of smokeless fuels—he may be regarded as one of the pioneers of low-temperature carbonisation.

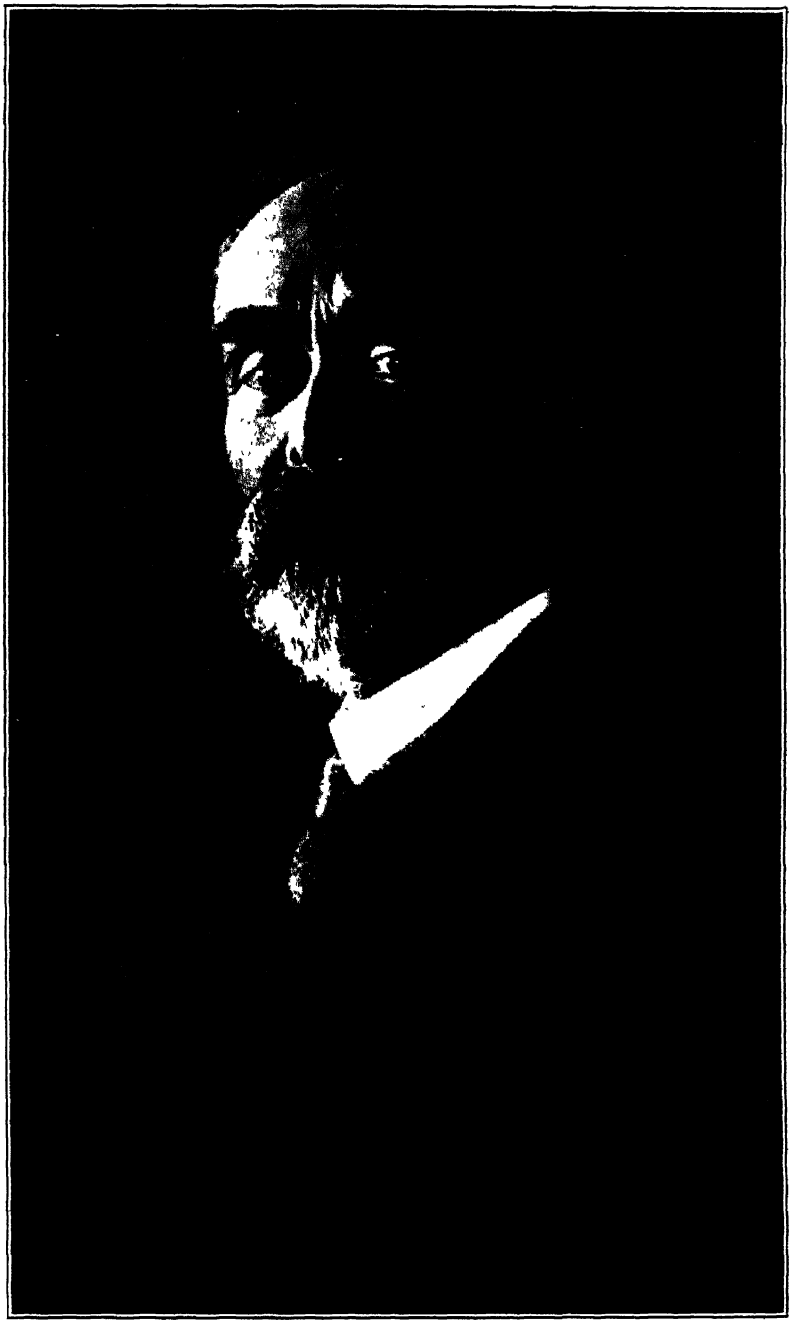
He took an active part in the foundation of the Faraday Society, was its first Treasurer (1903—1917), and frequently contributed to its *Transactions*. From 1908 to 1916 he was Honorary Secretary to the British Science Guild. He was active in the work of the Paint and Varnish Society, and for a time served as its President, and he was the first President of the Oil and Colour Chemists' Association (1918—1920).

Perkin helped to organise the Chemical Section of the Franco-British Exhibition (1908), and was a member of the juries of that exhibition and of the International Exhibitions held at Brussels (1910), Turin (1911), and Ghent (1913).

For his services to various Government departments during the war he was in 1920 appointed a Commander of the Order of the British Empire.

During the last year of his life his health failed, and he died on May 24th, 1928, in his 59th year.

Perkin married Elizabeth Margaret, daughter of Geo. Mackay of Edinburgh, who with their son and two daughters survives him.



A. J. G.

HENRY RICHARDSON PROCTER.

BORN MAY 6th, 1848; DIED AUGUST 17th, 1927.

AMONG the men of science who have devoted themselves to the improvement of our manufacturing arts, the subject of this notice, Henry Richardson Procter, acclaimed on every side as the pioneer of a scientific leather industry, occupies a conspicuous place of honour. His death has evoked tributes from all parts of the world acknowledging his services to the industry and celebrating his qualities as a scientific investigator, a teacher, and a man rich in qualities of mind and heart.

Henry Richardson Procter was born on May 6th, 1848, at Low-lights, North Shields, his parents both being descendants of the Quaker and tanning family of Richardson. His father maintained the old tannery and designed that Henry, his elder son, should succeed him. At the age of 14 Procter went to Bootham School, York, where, according to an autobiographical note, he had more training in science, for which he already showed an aptitude, than was common in schools of that day. After leaving school he was apprenticed to his father's business and made some efforts to apply his chemical knowledge to tanning, carrying on his scientific studies in an attic laboratory. Having passed the Government "South Kensington" Chemistry Examination, and so become a qualified teacher, he taught a small chemistry class in the town and in con-

H. R. PROCTER.

[*To face p.* 3300.]

nexion therewith was invited to a week's summer course at the Royal College of Chemistry in Oxford Street, London. There his talents so impressed the authorities that they persuaded him to return to London at Christmas for the rest of the term. At the end of the course he was head of the lists and obtained the full certificate. During part of this time he acted as volunteer assistant to Edward Frankland and Norman Lockyer and so became interested in astronomy. He also published, in conjunction with his relative, T. H. Waller, a translation of Kohlrausch's "An Introduction to Physical Measurements," one of the earliest laboratory books of practical physics to be generally used in this country.

Reluctantly refusing Lockyer's invitation to join the Eclipse expedition, then proceeding to India, Procter returned to his father's tannery and set to work with success in improving and expanding the manufacture. He had little taste for the business side of the industry and as competition within it had become very acute by the time his father died in 1888, he abandoned the paternal tannery and took up the post of chemist to the tanning firm of his relatives, Messrs. S. and J. Richardson, of Elswick, Newcastle-on-Tyne. Here he remained until, in 1890, he was invited by the Yorkshire College, Leeds, to take direction of a new department of applied chemistry which it had been decided to establish for the benefit of the leather industries. The offer, from a worldly point of view, was meagre, but happily the possession of some private means enabled Procter to seize what was to him a tempting opportunity of living in the scientific world and of devoting himself unrestrictedly to scientific work. He took up his post at Leeds early in 1891 and began with very simple accommodation and appliances to devise a course of instruction in the applied science of leather manufacture. In 1898 his department was transferred to a new building provided by the generosity of the Worshipful Company of Skinners of London. These excellent premises were laid out after Procter's design for teaching and research, and they included manufacturing plant on a scale sufficient to afford demonstrations and trials on a valid working scale.

In setting up this new department of applied science, Procter was confronted with the usual difficulty of securing students of adequate preliminary education and intellectual quality. He would have been glad indeed if he could have insisted that students coming to him had previously been equipped fully in fundamental sciences. His own educational and scientific standards were very high, but he was no pedant; he had sympathy with people whose outlook was strongly practical, and his teaching afforded a striking example of the way in which an interest and schooling in scientific

theory and scientific method can be inculcated by an approach from the side of practical problems. It could often be seen how under his guidance and the stimulus of a visible practical end, students previously reluctant would awaken to a perception of the value of chemical theory and apply themselves with zeal to serious scientific study. He produced by his three years course a type of student well trained to address himself to the scientific control and development of the processes of leather manufacture. Students soon came to Procter from all parts of the world and returned to put to effective use the training which they had received.

Before taking up work at Leeds, Procter had gone far towards bringing science to play its due part in the leather industry. His "Text-Book of Tanning," published in 1885, was the first serious effort in the application of science in tannery practice, and is recognised as having inaugurated a scientific era in the industry. It embodies a great deal of original work which he had done since the first publication, in his twenties, of papers on tannin analysis. The difficulty of applying scientific methods to the leather industry came at the outset in the basic substance of the old tannery process—What is tannin and how is the tanning value of a substance to be estimated for the purpose of both manufacture and commerce? The first question can only be answered in the vaguest way. There are many tannins, but they present great chemical variety and not much is known about their constitution. They are all derivatives of the aromatic series of carbon compounds, and, so far as is known, all contain either pyrocatechol or pyrogallol, and sometimes phloroglucinol. The pyrogallol tannins yield gallic acid as a decomposition product and many of them glucose. The pyrocatechol tannins contain protocatechuic acid and seem to yield no glucose. The tannins have the one common property of converting skins into leather, and for any scientific control of leather manufacture a standard method of estimating the tanning efficacy, one which will give reproducible results in different hands, is indispensable.

It was to this end that Procter's first efforts were directed, and he devoted great labour to developing the method based on the use of hide powder. During fifty years he returned continually to the subject and he took the principal part as Chairman of the International Commission in drawing up the official method of tannin analysis, published by the International Association of Leather Trades' Chemists in 1907. In the new international method adopted last year, the essential principles of the earlier one are retained.

Apart from his work on tannin analysis, Procter concerned himself with devising simple methods of chemical control for the various

operations of the tan-yard and in his laboratory the biological as well as the chemical aspect of tanning problems was always the subject of study. He took a very active part in the establishment of chrome tanning. He gave to the trade his well-known formula for the making of single-bath chrome liquors and his teaching of the scientific principles of the new methods contributed in a very important way to their adoption and success.

Behind all Procter's active work of the kind just described was the constant occupation of his mind with the fundamental science of colloids. He showed in relation to the newer physical chemistry his remarkable power of bringing himself fully abreast of the times in any special part of theoretical science that he wanted to use, and so equipped he entered upon his *magnum opus*. This was a very complete investigation of the conditions determining the state of equilibrium which is established when gelatin jellies are brought into contact with solutions of acids.* The attainment of equilibrium in such systems is usually associated with swelling or contraction effects which depend on the nature and concentration of the acid solution and are also affected by the presence of neutral salts.

Procter recognised clearly that such a system is one to which the Donnan theory of membrane equilibria can be applied. In virtue of its basic properties, gelatin combines with acids to form gelatin salts; on ionisation these yield a gelatin kation which is of relatively very large dimensions and consequently unable to pass through membranes which are readily permeable to ionic or molecular entities of smaller size. The interface between a gelatin jelly and its aqueous environment may be regarded as the equivalent of an actual membrane, for the gelatin ions are necessarily confined to the jelly side of the interface, whereas the anions associated with the gelatin kations may pass freely from one side to the other under the influence of osmotic forces, subject, of course, to such restrictions as are attributable to the intervention of electrical forces between the charged ions.

When a gelatin jelly is immersed, for instance, in a solution of hydrochloric acid, the latter passes through the interface, forming the salt gelatin hydrochloride, and ultimately a state of equilibrium is established in which we have gelatin ions, hydrogen ions, and chlorine ions on the jelly side of the interface, whilst hydrogen ions and chlorine ions are in the outer solution. In accordance with Donnan's theory, this equilibrium satisfies the relation

$$[H^+]_1 \cdot [Cl^-]_1 = [H^+]_2 \cdot [Cl^-]_2$$

* The writer has to thank Professor H. M. Dawson for summarising this work. He is also indebted to Mr. J. R. Atkin and Mr. F. C. Thompson of the Leather Industries Department of Leeds University for valuable assistance.

where $[H^+]_1$ and $[Cl^-]_1$ are the concentrations of the hydrogen and chlorine ions in the inner solution and $[H^+]_2$ and $[Cl^-]_2$ are the corresponding quantities for the outer solution. Since both solutions must be electrically neutral, we may also write

$$[G^+] + [H^+]_1 = [Cl^-]_1$$

where $[G^+]$ is the concentration of the gelatin ion. From these relations, it follows as a mathematical consequence that the concentration of the hydrochloric acid when in the jelly must always be less than that in the external solution, and Procter's numerous experiments showed this was actually the case. It follows further that the total ion concentration within the jelly must be greater than that of the external solution. This means that the osmotic pressure within the jelly must be greater than that of the outer solution, and Procter recognised in this inequality the cause of the swelling which, according to his views, proceeds until the difference in the osmotic pressures is counterbalanced by the forces of cohesion in the gel.

This theory, elaborated subsequently in conjunction with J. A. Wilson, has been found to give a satisfactory account of the phenomena associated with the swelling of gelatin. In particular, experiments have shown that there is a close parallelism between the degree of swelling and the difference in the ionic concentrations of the inner and outer solutions in that both pass through a maximum as the acidity of the solution, measured by the p_H value, increases. The maxima occur, in fact, at the same p_H value (compare Atkin, *J. Soc. Leather Trades' Chemists*, 1920, 4, 248). The theory also affords a simple account of the repression of the swelling which takes place when a salt of the corresponding acid is added to the outer solution.

Procter's work on gelatin thus affords a very notable example of the successful application of the theory of membrane equilibria. The significance of his work from a purely scientific point of view is to be found in the highly satisfactory issue of this attempt to deal with a problem which, even in its essential outlines, had previously been quite obscure. As a result of his investigations, this type of problem was brought within the range of application of modern physico-chemical principles, and in this way he provided a rational basis for the further investigation of colloid systems which is recognised to be of the greatest importance from the purely scientific as well as from the technical point of view. The late Jacques Loeb wrote of Procter's theory of protein swelling as "one of the most ingenious and original contributions to modern science."

Of Procter's contributions to the literature of his subject the "Text-Book of Tanning" has already been mentioned. This was followed in 1898 by the publication of the "Leather Industries

Laboratory Book" and in 1903 by the "Principles of Leather Manufacture." The "Principles" at once took the position which it has retained, that of a standard masterpiece of applied science literature. It has been translated into many languages, including Japanese.

For a full account of Procter's work and the testimony of those who profited from it, the reader is referred to the "Procter Memorial Issue" of the *Journal of the International Society of Leather Trades' Chemists*. Typical of this testimony may be quoted the words of Professor V. Kubelka of Brünn, who, after expressing his own indebtedness, says: "Je suis certain qu'il y a dans tous les pays du monde des centaines de chemistes de cuir qui se rappelleront avec reconnaissance que pour eux aussi les libres de H. Procter étaient les premiers phares qui les ont conduit dans l'étude de la chimie de cuir." A list of 121 publications gives some idea of the variety of Procter's scientific work and the range of his technical services. Among these services was the foundation in 1897 of the Society just mentioned, which from small beginnings grew to include all the leather chemists of Europe and in other and more remote countries. Procter was its first President and always its central influence.

Procter held his professorship at Leeds until, in 1913, he reached the age of retirement. In anticipation of this event steps had been taken by the leather industry to mark the event by some suitable memorial of the man and his services. The story may perhaps be best expressed in Procter's words: "On my retirement in 1913 a considerable sum, over £1800, was subscribed by my friends as an acknowledgment of what I had done for the chemistry of the trade, and as I have fortunately a modest independent income, I thought that this (the fund) could be most usefully devoted to the establishment of a special laboratory to investigate the underlying scientific problems, which, though not likely to be of immediate commercial value, are yet the materials on which sound advance can be based. The money sufficed to erect the laboratory, but unfortunately not to endow it, but it is now open to qualified students of all nations at fees calculated merely to cover their actual cost, and the University, which acts as a Trustee under a Deed-poll, has so far generously borne a good part of the actual working expenses. With more money and more research students, its usefulness might be greatly increased."

Procter's successor, in the person of Dr. E. Stiasny, had already been chosen and had been acting for some time with great success as assistant professor. He now took the vacant Chair and Procter passed into the new Research Laboratory, where with J. A. Wilson

he completed his work on gelatin. The formal opening of the Laboratory by Sir William Ramsay and the attendance of representatives of the industry from all parts of the world was to have taken place in October, 1914. To this plan the outbreak of war put an end. Not only so, but in August Professor Stiasny was in Austria, his native country. In this emergency Professor Procter resumed his old position and busied himself with important work for the War Office, remaining in office till 1918. He was then succeeded by his old pupil, Professor McCandlish, but he continued to work a good deal in his laboratory. In 1923 he sold his house at Ilkley and retired to Newlyn, Cornwall, where, in proximity to his artist son, Ernest, he spent the evening of his life in comfort and content, pursuing old hobbies of handicraft and art and enjoying the society of friends. Towards the end of 1926 he was compelled to take to his bed and he died on August 17, 1927. He was buried at St. Hilary, some miles from Penzance.

Procter had married in 1874 Emma Watson of Newcastle, who died in 1901. He has left a daughter and two sons, the elder, Mr. J. W. Procter, a distinguished architect, the younger the well-known artist, Mr. Ernest Procter.

Procter's success and the sway which he acquired were largely bound up with his remarkable personality. Though he found himself obliged to withdraw from the Society of Friends, he retained in high degree the most admired characteristics of that community. The gentleness of his nature, his single-heartedness and companionableness endeared him to all who knew him and, as Sir Michael Sadler has said most truly, "no Indian guru had disciples more devoted, more respectful." His tastes and talents were of the widest range. In the country he was naturalist, rock-climber, and artist; he was a much travelled man and a good linguist. In leisure hours at home he was a gardener and a craftsman in mechanical and decorative arts and a great reader.

The character of Procter's mind was as markedly philosophical as scientific. The setting up of a "professor of leather" gave scope for a good deal of jest and indeed for some indignation in more austere academic circles. It was a constant delight to his colleagues to witness the effect of Procter's conversation in the University refectory with guests from such circles. He revelled in dialectic and could have excelled any of his colleagues in the arts of casuistry. He exercised a strong quiet influence on University affairs, most of all perhaps by demonstrating in himself and his work the way in which applied science may justify itself among university studies.

The establishment of the unique personal memorial of an inter-

national Research Laboratory and the bestowal of the Fellowship of the Royal Society came towards the end of Procter's life and gave him deep gratification, but he had done his work and given all his discoveries to the industry, seeking neither honours nor rewards.

A. S.

MADYAR GOPAL RAU.

BORN JUNE 17th, 1891; DIED MAY 21ST, 1928.

MADYAR GOPAL RAU, who died of enteric fever at Amritsar on the 21st May, 1928, was born at Mangalore on the 17th June, 1891. His father, Manjunathayya, was a landholder and his mother, Chandravati, was the daughter of a judicial officer in the employ of the East India Company and later of the Madras Government. He received his early education at the Ganapati High School and the Canara High School, matriculating from the latter in 1909 and then entering the Government College, Mangalore (University of Madras). After passing the Intermediate Examination in 1911, he left Mangalore for the Presidency College, Madras. Here his ability was early recognised and he qualified for the B.A. degree in 1913, being at the top of the class list. Two years later he took an Honours degree in chemistry, being once more at the head of the list. He was awarded a University Research Studentship and for the following three years he worked at research in organic chemistry under the direction of the writer. During part of this period he was called upon to take complete charge of the teaching of organic chemistry at the Presidency College and he thus had an early opportunity of showing his aptitude for teaching. He was in 1918 appointed a lecturer in the College. In 1920 he moved to the Forest Research Institute and College, Dehra Dun, as Assistant to the Forest Chemist and he remained there until, in 1925, he was appointed Professor of Chemistry at the Khalsa College, Amritsar. He held this post at the time of his death and in addition he had for the last year been Principal of the College.

Nearly all Gopal Rau's research work had been carried out in collaboration with the writer. His early work was concerned with the nitration and bromination of acetamidomethoxybenzoic acids (J., 1917, **111**, 70, 221; 1918, **113**, 22, 783) and with an attempt to synthesise morindone (J., 1921, **119**, 1339), but after proceeding to Dehra Dun he worked mainly on natural products. He published a number of papers on essential oils and fats which appeared in the Journal and in the Indian Forest Records (J., 1922, **121**, 876; 1923, **123**, 550; *Ind. For. Rec.*, 1922, **9**, 95, 111; 1925, **11**, 197, 207; *J. Ind. Inst. Sci.*, 1926, **9**, *A*, 111). His most important work

was on the oxidation of Δ^3-carene, the constituents of the essential oil from *Blumea Malcomii*, and on the effect of anti-catalysts on the rate of oxidation of some dicyclic terpenes. He also collaborated in two papers on the constitution of abietic acid. After his appointment to Amritsar he had little time for original work, as he was much occupied with teaching and administrative duties and the facilities for laboratory work were not good. Although he never ceased to work in the laboratory, he only published one paper on "The essential oil from the flower-heads of *Perovskia atriplicifolia*, Benth." (*J. Ind. Chem. Soc.*, 1926, **3**, 141). He felt very keenly his lack of opportunity for work and he had arranged to visit England in September in order to work with Prof. Robinson at University College, but this was not to be. Though physically never very strong, he was a keen cricketer and tennis player and by his premature death at the age of 37 India loses an organic chemist of a type all too rare in that country, a loss which she can ill afford. Although not possessing great originality, Gopal Rau was a fine experimentalist and an inspiring teacher. In May, 1912, he married Miss Giriji Bai of Honavar (Bombay), who survives him.

INDEX OF SUBJECTS, 1928.

A.

Acetaldehyde, *di*chloro-, condensation of phenols with (CHATTAWAY and MORRIS), 3241.

Acetamide, cyano-, addition of, to coumarins (SESHADRI), 166.

Acetanilide, *o*-bromo-, nitration of (GIBSON and JOHNSON), 3092.

N-chloro-, decomposition of, by heat (BRADFIELD), 351.

*tetra*nitro- (FLÜRSCHEIM and HOLMES), 3046.

2-nitro-4-thiocyano- (CHALLENGER and PETERS), 1372.

Acetanilides, fluoro-*mono*- and *-di*chloro- (INGOLD and VASS), 422.

Acetic acid, inert salt effects in catalysis by, and its salts (DAWSON and KEY), 1248.

lead *sub*salt ("Goulard's extract"), and its reaction with phenols (GIBSON and MATTHEWS), 596.

magnesium salt, constitution of solutions of (GOODE, BAYLISS, and RIVETT), 1950.

chloroanthranyl esters (BARNETT and WILTSHIRE), 1824.

ethyl ester, catalysis by hydrochloric acid of hydrolysis of (DAWSON and LOWSON), 2146.

Acetic acid, chlorobromo-, racemic, resolution of, and its salts (BACKER and MOOK), 2125.

Acetic anhydride, physical properties of (JONES), 1193.

miscibility of (JONES and BETTS), 1177.

action of bromine on (WATSON and ROBERTS), 2779.

Acetoacetic acid, ethyl ester, condensations with (FRANKLIN and SHORT), 591.

condensation of ketones with (JUPP, KON, and LOCKTON), 1638.

interaction of distyryl ketones with (HEILBRON and HILL), 2863.

δ-aminosemicarbazone and carbohydrazones of (MUNRO and WILSON), 1259.

Acetone, water catenary in iodination of (DAWSON and KEY), 543.

Acetone, compound of lithium hydrogen sulphite and (FRIEND and POUNDER), 2248.

cyanohydrin, preparation of (WELCH and CLEMO), 2629.

Acetonediphenylene-2:2′-mercaptol (BARBER and SMILES), 1147.

4-Acetonyl-2:3-dimethyl-1:4-benzopyran (HILL), 257.

4-Acetonyl-3-phenyl-2-methyl-1:4-benzopyran (HILL), 258.

Acetophenone δ-phenylthiosemicarbazone (STEPHEN and WILSON), 1422.

Acetophenone, chloro-, formation of, from benzoyl chloride (BRADLEY and SCHWARZENBACH), 2904.

ω-chloro-3:4-*di*hydroxy-, and *p*-nitro-ω-hydroxy-, acetyl derivatives (BRADLEY and SCHWARZENBACH), 2907.

ω:4-*di*hydroxy-, acetyl and benzoyl derivatives (ROBERTSON and ROBINSON), 1465.

Aceto-*m*-toluidide, 5-bromo- (MCALISTER and KENNER), 1915.

ω-Acetoxy-4-benzyloxy-3:5-dimethoxyacetophenone (BRADLEY and ROBINSON), 1560.

Acetoxymercuriacetamidodiphenyls (BELL), 2777.

3-Acetoxymercuriaceto-*p*-toluidide (BELL), 2779.

4-Acetoxy-3-methyltetraphenylmethane (BOYD and HARDY), 637.

Acetyl bromide and chloride, speed of bromination of (WATSON), 1137.

*per*oxide, decomposition of (WALKER), 2040.

Acetylene, action of carbon disulphide on (BRISCOE, PEEL, and ROBINSON), 2857.

action of sulphur on, up to 650° (PEEL and ROBINSON), 2068.

α-Acetylglutaric acid, and α-bromo-, ethyl esters (CLEMO and WELCH), 2626.

Acetylmethylanthranilic acid, action of phosphorus pentachloride on (HEILBRON, HOLT, and KITCHEN), 934.

Acetylmethylanthranilic acid, 5-bromo- (HEILBRON, HOLT, and KITCHEN), 941.

2-Acetyl-3-methyl-1:2-dihydrobenzthiazole, 1-imino-, and its *tri*bromide (HUNTER and STYLES), 3022.

5-Acetyl-1-methyl-3:4-dipropenyl*cyclo*pentan-1-ol (EVANS and FARMER), 1647.
1-Acetyl*cyclo*pentane-1-acetic acid, and its derivatives (BARDHAN), 2601.
***O*-Acetylsyringoyl chloride** (BRADLEY and ROBINSON), 1552.
***O*-Acetylsyringoylacetoacetic acid**, ethyl ester (BRADLEY and ROBINSON), 1553.
Acetyltetramethyl*cyclo*pentylamines (SHOPPEE), 1670.
Acid, $C_8H_{12}O_4$, and its salts, from oxidation of α-phellandrene (HENRY and PAGET), 77.
Acids, effects of spatial position of substituents on strength of (HEY), 2321; (FLÜRSCHEIM), 3039.
variation of catalytic activity of, with concentration (DAWSON, HALL, and KEY), 2844.
inert salt effects in catalysis by (DAWSON and KEY), 1239.
aliphatic, action of bromine on (WATSON), 1137.
*di*carboxylic, crystallography of (CASPARI), 3235.
*di*basic, electrometric titration of (GANE and INGOLD), 1594, 2267.
fatty, degradation of, by mould fungi (WALKER and COPPOCK), 803; (COPPOCK, SUBRAMANIAM, and WALKER), 1422.
organic, adsorption of, on animal charcoal (GRIFFIN, RICHARDSON, and ROBERTSON), 2705.
unsaturated, influence of alkyl substituents on αβ–βγ change in (GOLDBERG and LINSTEAD), 2343.
and their esters, addition of halogens to (HANSON and JAMES), 1955, 2979.
olefinic, action of bromine water on (READ and REID), 745.
Aconite, Chumbi, alkaloids from (HENRY and SHARP), 1105.
Indian, alkaloids of (HENRY and SHARP), 1105; (SHARP), 3094.
Address, presidential (BAKER), 1051.
Adipic acid, electrometric titration of (GANE and INGOLD), 1598.
l-menthyl hydrogen ester (RULE, HAY, and PAUL), 1358.
Adsorption and constitution (GRIFFIN, RICHARDSON, and ROBERTSON), 2705.
of vapours on glass or quartz (SMITS), 2952.
Affinity, residual, and co-ordination (MORGAN and BURSTALL), 143; (MORGAN and CASTELL), 3252.
α- and β-Alanines, action of nitrous acid on (TAYLOR), 1901.
Alcohols, equilibria between metallic salts and (LLOYD, BROWN, BONNELL, and JONES), 658.
Alcoholates, dissociation pressures of (LLOYD, BROWN, BONNELL, and JONES), 658.
Aldehydes, condensation of, with ketones of the morphine group (GULLAND), 702.
aromatic, effect of substitution in, on stability of their cyanohydrins (LAPWORTH and MANSKE), 2533.
Aldehydes, chloro-, aliphatic, polymerides (CHATTAWAY and KELLETT), 2709.
Aldehydomethylphenol semicarbazones (BELL and HENRY), 2222.
Aldehydomethyl*iso*propylphenol semicarbazones (BELL and HENRY), 2219, 2221.
3-Aldehydo-5-methyl-2-*iso*propylphenyldicarvacrylmethane, 4-hydroxy-, semicarbazone (BELL and HENRY), 2221.
5-Aldehydo-3:4:8-trimethoxyphenanthrene, and its derivatives (GULLAND and VIRDEN), 926.
Alizarin, toluene-*p*-sulphonyl derivative, and its methyl ether (PERKIN and STOREY), 241.
Alkaloids, aconite. See under Aconite.
aporphine. See Aporphine alkaloids.
lupin (CLEMO and LEITCH), 1811.
Alkyl halides, interaction of magnesium with (RUDD and TURNER), 686.
β-Alkylacrylic acids, α-cyano-, alkylation of esters of (McRAE and MANSKE), 484.
Aluminium, surface oxidation of (BANNISTER), 3163.
valency of, in its complex salicylato-derivatives (BURROWS and WARK), 222.
Aluminosalicylic acid, and its salts, and their derivatives (BURROWS and WARK), 225.
Amines, equilibria of cresols with (PUSHIN and SLADOVIĆ), 2474.
constitution of the supposed *N*-methylenesulphurous acid derivative of (NEWBERY and PHILLIPS), 116.
aromatic substituted, action of, on camphoric anhydride (SINGH, AHUJA, and LAL), 2410.
tertiary aromatic substituted, nitration of (CLEMO and SMITH), 2414.
Amines, chloro-, effect of constitution on hydrolysis of (SOPER and SMITH), 138.
Amino-acids, aliphatic, action of nitrous acids on (TAYLOR), 1897.
Amino-compounds, action of nitrous acid on (TAYLOR), 1099, 1897.

Ammonia, action of nitrous acid on (TAYLOR), 1104.
liquid, ionisation of aromatic nitro-compounds in (GARNER and GILLBE), 2889.
Ammonium bromide, pressure and density of moist saturated vapour of (SMITS and PURCELL), 2936.
chloride, pressure and density of moist saturated vapour of (SMITS and DE LANGE), 2944.
*poly*sulphides (MILLS and ROBINSON), 2326.
thiocarbonates (MILLS and ROBINSON), 2330.
Ammonium salts, quaternary, degradation of (STEVENS, CREIGHTON, GORDON, and MACNICOL), 3193.
Amylene, action of bromine water on (READ and REID), 1491.
n-**Amyloxyacetic acid**, and its *l*-menthyl ester and chloride (RULE, HAY, and PAUL), 1356.
1-**Amyl***cyclo***telluripentane**, ε-bromo-, bromide, ε-chloro-, chloride and ε-iodo-, iodide (MORGAN and BURGESS), 325.
Analysis, potentiometric titration (CAVANAGH), 843, 855.
Anethole, action of bromine water on (READ and REID), 1489.
Anhydronium bases, formation of (KERMACK and SLATER), 789.
Anilides, chlorination of (BRADFIELD), 351; (ORTON, SOPER, and WILLIAMS), 998; (BRADFIELD and JONES), 1006, 3073.
Aniline, action of, on glutamic acid (GRAY), 1264.
compound of benzoylacetonitrile and, and its derivatives (KRISHNAMURTI), 416.
Aniline, 3-fluoro-4-chloro- (INGOLD and VASS), 422.
halogeno- and halogenonitro-derivatives, and their acetyl derivatives (BRADFIELD, ORTON, and ROBERTS), 783.
*penta*nitro- (FLÜRSCHEIM and HOLMES), 3041.
2-nitro-4-thiocyano- (CHALLENGER and PETERS), 1372.
4-Anilino-3-*o*-anilinophenylmethylcarbamyl-1-methyl-2-methylene-1:2-dihydroquinoline (HEILBRON, HOLT, and KITCHEN), 939.
4-Anilino-3-*o*-carbethoxyphenylmethylcarbamyl-1-methyl-2-methylene-1:2-dihydroquinoline (HEILBRON, HOLT, and KITCHEN), 939.
1-**Anilino-1-cyano-4-methyl***cyclo***hexane**, and 1-*p*-nitro- (BETTS and PLANT), 2073.
1-**Anilino-4-methyl***cyclo***hexane-1-carboxylic acid**, and its amide, and 1-*p*-amino-, and 1-*p*-nitro- (BETTS and PLANT), 2073.
Anionotropic change, mechanism of (BURTON), 1650.
Anisic acid, condensation of chloral with (CHATTAWAY and CALVET), 2913.
Anisidine, chlorothio-, and their derivatives, and 6-nitro-3-thio- (HODGSON and HANDLEY), 163.
Anisole, 2-bromo-4-nitro- (BURNS, MCCOMBIE, and SCARBOROUGH), 2934.
3-chloro-2-amino-, -bromo-, -cyano-, -iodo-, and -thio-, and their derivatives, and 3-chloro-2:6-*di*bromo- (HODGSON and KERSHAW), 192.
5-chloro-4-nitro-3-hydroxy- and 5-chloro-4-nitroso-3-hydroxy- (HODGSON and WIGNALL), 330.
3-chloro-4-nitrothio- (HODGSON and HANDLEY), 166.
p-nitro-, condensation of chloral with (CHATTAWAY and CALVET), 2913.
Anisole-2-diazo*per*bromide, 3-chloro- (HODGSON and KERSHAW), 192.
Anisole-2-diazoimide, 3-chloro- (HODGSON and KERSHAW), 193.
Anisyl-2-hydrazine, 3-chloro-, hydrochloride (HODGSON and KERSHAW), 193.
Anisylthymylacetonitrile (BELL and HENRY), 2225.
Annual General Meeting, 1034.
Anthocyanins, synthesis of (ROBERTSON, ROBINSON, and STRUTHERS), 1455; (ROBERTSON and ROBINSON) 1460.
Anthracene derivatives, absorption spectra of (BARNETT, COOK, and ELLISON), 885.
synthesis of *meso*-alkyl and -aryl derivatives of (BARNETT and COOK), 566; (BARNETT and WILTSHIRE), 1822.
Anthracene, 1-chloro-9:10-*di*bromo- (COOK), 2808.
Anthrapurpurin, and its acetyl and benzoyl derivatives, methyl ethers (PERKIN and STOREY), 235.
9-Anthrone, 2-chloro- (BARNETT and WILTSHIRE), 1823.
Antimony alloys with arsenic (MANSUMI), 2107.
Antimony organic compounds (GODDARD and YARSLEY), 719.
Antimony cathodes. See under Cathodes.
Aporphine alkaloids, synthesis of (GULLAND and HAWORTH), 581, 1132, 1834, 2083.
Aromadendrene, chemistry of (BRIGGS and SHORT), 2524.

Aromadendrone, and its derivatives (BRIGGS and SHORT), 2528.
Aromatic compounds, formation of. from hydroaromatic compounds (HINKEL and HEY), 1200, 2786.
substitution in (FLÜRSCHEIM and HOLMES), 448, 453, 1607, 2230.
directive action of groups in (BAKER, COOPER, and INGOLD), 426.
side-chain substitution in (INGOLD and ROTHSTEIN), 1217.
activation of halogen atoms by a nitro-group in the nucleus of (BREWIN and TURNER), 334.
polynuclear, molecular configuration of (MCALISTER and KENNER), 1913; (KENNER and TURNER), 2340.
Arrhenius Memorial Lecture (WALKER), 1380.
Arsenic alloys with antimony (MANSURI), 2107.
Arsenic:—
Arsenic acid, second dissociation constant of (HUGHES), 502.
Arsenious acid, first dissociation constant of (HUGHES), 502.
Arsenic organic compounds (GIBSON and JOHNSON), 92; (NEWBERY and PHILLIPS), 2375.
heterocyclic (NEWBERY, PHILLIPS, and STICKINGS), 3051; (BALABAN), 3066; (STICKINGS), 3131; (PHILLIPS), 3134.
Arsenobenzene, 4-amino-, and its hydrochloride (NEWBERY and PHILLIPS), 120.
Arsenobenzenes, *di*aminodihydroxy-, mono- and di-acetyl derivatives (BALABAN), 811.
Arsenobenzenedimethylenesulphurous acid, *di*amino- and *di*aminodihydroxy-, sodium salts, preparation of (NEWBERY and PHILLIPS), 124.
Arsenobenzene-*N*-methylenesulphurous acid, 3 3′-*di*amino-4:4′-*di*hydroxy-, sodium salt, preparation of (NEWBERY and PHILLIPS), 126.
Arsenobenziminazoles (PHILLIPS), 3137.
Arseno-1:4-benz*iso*oxazines, *di*aminodihydroxy-, and their diacetyl derivatives, and *di*hydroxy- (NEWBERY, PHILLIPS, and STICKINGS), 3056.
6:6′-Arseno-(2:3-dihydro-1:4-benz*iso*oxazine) (NEWBERY, PHILLIPS, and STICKINGS), 3064.
Arsonium salts, aromatic, nitration of (INGOLD, SHAW, and WILSON), 1280.
Aryl halides, interaction of magnesium with (RUDD and TURNER), 686.
effects of nitro-, carboxyl, and sulphonic acid groups on hydrolysis of (DAVIES and WOOD), 1122.
2-Arylcinnamic acids, 2-amino-, isomeric (GULLAND and VIRDEN), 1478.
Atoms and spectra (FOWLER), 764.
Atomic weight of boron (COUSEN and TURNER), 2654.
Atropine sulphate, spontaneous resolution of (ANDERSON and HILL), 993.
Azelaic acid, electrometric titration of (GANE and INGOLD), 1598.
l-menthyl hydrogen ester (RULE, HAY, and PAUL), 1358.
Azobenzene, substitution products of (BURNS, MCCOMBIE, and SCARBOROUGH), 2928.
Azobenzene, halogeno*di*hydroxy-derivatives, and their derivatives (HUNTER and BARNES), 2053.
*tetra*halogeno*di*hydroxy-derivatives, (HUNTER and BARNES), 2060.
p-hydroxy-, halogeno-derivatives (HUNTER and BARNES), 2058.
Azo-dyes, effect of substituents on the colour of (HODGSON and HANDLEY), 162.
Azoimide, dissociation constant of (HUGHES), 502.
***o*-Azophenol**, *tetra*halogeno-derivatives of (HUNTER and BARNES), 2058.
***o*- and *p*-Azophenols**, halogeno-derivatives of (HUNTER and BARNES), 2051.
Azoxybenzene, 4:4′-*di*chloro- (BURNS, MCCOMBIE, and SCARBOROUGH), 2933.
Azoxybenzylideneacetophenones (NISBET), 3122.
Azoxybenzylidene-*p*-bromoanilines (NISBET), 3123.
***m*-Azoxybenzylidene-*p*-toluidine** (NISBET), 3124.
Azoxy-compounds (NISBET), 3121.
2-Azoxystyryl-3-methylchromones (NISBET), 3123.

B.

Balance sheets of the Chemical Society and Research Fund. See Annual General Meeting, 1034.
Barium hyponitrite (NEOGI and NANDI), 1454.
Batyl alcohol, and its derivatives (HEILBRON and OWENS), 944.
Behenolic acid, synthesis of (BHATTACHARYA, SALETORE, and SIMONSEN), 2678.
Benzaldehyde, compound of lithium hydrogen sulphite and (FRIEND and POUNDER), 2248.
and *o*-, *m*-, and *p*-nitro-, 3-chloroanisyl-2-hydrazones of (HODGSON and KERSHAW), 193.

Benzaldehyde, *p*-bromo-, semicarbazone (INGOLD and SHOPPEE), 407.
halogenohydroxy-, halogenonitrohydroxy-, and their derivatives (HODGSON and JENKINSON), 2272.
o-hydroxy-, Gattermann synthesis of (BELL and HENRY), 2215.
nitro-, phenylhydrazones, influence of groups on colours of (HODGSON and HANDLEY), 1882.
Benzaldehydediphenylene-2:2′-mercaptal (BARBER and SMILES), 1146.
Benzaldoxime, nitration of, and its derivatives (BRADY and MILLER), 337.
Benzanilide, thio-, thermal decomposition of (CHAPMAN), 1894.
Benzarsazinicphenarsazinic acids, and their sodium salts (GIBSON and JOHNSON), 2213.
5:6-Benz-4-carboline, fluorescence of, and its derivatives (KERMACK and SLATER), 32, 789.
Benzene, velocity measurements in relation to substitution in (BRADFIELD and JONES), 3073.
nucleus, formation of rings attached to (TITLEY), 2571.
Benzene, 1-bromo-3-iodo-6-nitro-, and -4:6-*di*nitro-, and 1-chloro-3-bromo-6-nitro- (MAYES and TURNER), 693.
bromonitro-, chloronitro-, and iodonitro-derivatives, reactivities of (BREWIN and TURNER), 332.
p-fluorochloro-, nitration of (INGOLD and VASS), 2265.
fluorochloro- and fluorochloronitro-derivatives (INGOLD and VASS), 422.
m-*di*halogeno-derivatives, nitration of (MAYES and TURNER), 691.
2:4:6-*tri*nitro-1:3:5-*tri*amino- (FLÜRSCHEIM and HOLMES), 3045.
p-*di*thiocyano-, preparation and nitration of (CHALLENGER and PETERS), 1371.
Benzeneazoacetoacetic acid, 2:4:6-*tri*bromo- and 2:4:6-*tri*chloro-, ethyl esters (CHATTAWAY and DALDY), 2761.
Benzeneazoethylenes, chloro- and chlorobromo-derivatives (CHATTAWAY and DALDY), 2758.
4-Benzeneazo-5-hydroxy-2:2:3:3-tetramethyl-Δ⁴-*cyclo*pentenone, 2′:4′:6′-*tri*bromo- (SHOPPEE), 2364.
1-Benzeneazo-β-naphthaquinone-1-sulphonic acid, 1-3′-nitro-, sodium salt (ROWE, HIMMAT, and LEVIN), 2558.
5-Benzeneazo-*o*-4-xylenol (HINKEL, AYLING, and BEVAN), 2532.
Benzene-2:4-disulphonic acid, chloro-, preparation of, and its derivatives (DAVIES and WOOD), 1125.
Benzene-*p*-sulphinic acid, chloro-, preparation of, and its ammonium salt (DAVIES and WOOD), 1126.
1-Benzenesulphonamido-8-nitronaphthalene (MILLS and ELLIOTT), 1298.
Benzenesulphonic acid, bornyl and menthyl esters, decomposition and hydrolysis of (PATTERSON and MCALPINE), 2464.
Benzenesulphonic acid, 2-iodo-, sodium salt (BARBER and SMILES), 1143.
p-nitro-, esters and amides of (BELL), 2776.
Benzenesulphonyl-1-naphthylglycine, and its ethyl ester (MILLS and ELLIOTT), 1302.
1-Benzenesulphonyl-8-nitro-1-naphthylaminoacetic acid, brucine salt and ethyl ester (MILLS and ELLIOTT), 1299.
Benzenesulphonyl-8-nitro-1-naphthylglycine, optically active (MILLS and ELLIOTT), 1291.
Benzene-2:4:6-trisulphonic acid, chloro-, preparation of, and its potassium salt (DAVIES and WOOD), 1125.
Benzidine, 2:6-*di*bromo-, and 2-chloro- (BURNS, MCCOMBIE, and SCARBOROUGH), 2935.
3-nitro-, and its diacetyl derivative (LE FÈVRE and TURNER), 254.
3:3′-*di*nitro- (LE FÈVRE and TURNER), 252.
Benzil benzyl mercaptol dioxide (CHIVERS and SMILES), 699.
Benzil, *mono*- and *di*-nitro-, and their derivatives (CHATTAWAY and COULSON), 1080.
4:4′-*di*nitro-, preparation of, and its derivatives (CHATTAWAY and COULSON), 1361.
Benzildiphenylene-2:2′-mercaptol (BARBER and SMILES), 1147.
Benzildi-*d*-3-(α-phenylethyl)semicarbazone (HOPPER and WILSON), 2488.
Benziminazoles 2-substituted (PHILLIPS), 2393.
Benziminazole-5-arsinic acid, 2-amino- (STICKINGS), 3133.
Benziminazolearsinic acids (PHILLIPS), 3134.
Benziminazole-2-thioglycollic acid (STEPHEN and WILSON), 1420.
Benziminazolyl-2-α-thiol-*n*-butyric acid, and its ethyl ester (STEPHEN and WILSON), 1419.
Benziminazolyl-2-α-thiolpropionic acid, and its ethyl ester (STEPHEN and WILSON), 1419.

Benzoic acid, esters, growing-chain and *ortho*-effects in (RULE, HAY, and PAUL), 1347.
alkyl esters, electronic affinity of radicals in (ZAKI), 983.
Benzoic acid, *o*-bromo-, -chloro-, and -iodo-, *d*-β-octyl esters (RULE, HAY, NUMBERS, and PATERSON), 182.
3-bromo-5-amino-, 3-bromo-5-iodo-, 3-chloro-5-amino-, 3-chloro-5-iodo-, 5-iodo-3-nitro-, and their derivatives (MCALISTER and KENNER), 1914.
o-cyano-, methyl ester, action of magnesium phenyl bromide on (BOYD and LADHAMS), 2089.
p-nitrothiol-, *m*-tolyl ester (BARBER and SMILES), 1147.
Benzoin, resolution of, and its phenylethylsemicarbazone (HOPPER and WILSON), 2483.
Benzonitrile, electrical conductivity of uni-univalent salts in (MARTIN), 3270.
nitration of (BAKER, COOPER, and INGOLD), 430.
Benzophenyl-3-nitrobenzylamide (REILLY, MOORE, and DRUMM), 564.
Benzopropylamidopropylarsinic acid, *m*-nitro- (GOUGH and KING), 2441.
1:4-Benz*iso*oxazine, 8-amino-3-hydroxy-, and its hydrochloride and acetyl derivative (BALABAN), 3070.
1:4-Benz*iso*oxazines, amino- and nitro-3-hydroxy-, and their derivatives (NEWBERY and PHILLIPS), 3046.
1:4-Benz*iso*oxazine arsenoxides, 8-amino-3 hydroxy- and 3-hydroxy- (NEWBERY, PHILLIPS, and STICKINGS), 3056.
1:4-Benz*iso*oxazinearsinic acids, aminohydroxy-, *mono*- and *di*-hydroxy-, chlorohydroxy-, and nitrohydroxy-, and their derivatives (NEWBERY, PHILLIPS, and STICKINGS), 3054.
aminohydroxy-, hydroxy- and nitrohydroxy-, and their derivatives (BALABAN), 3068.
1:4-Benz*iso*oxazine-8-hydroxychloroarsine, 8-amino-3-hydroxy-, hydrochloride (NEWBERY, PHILLIPS, and STICKINGS), 3059.
Benzoxazole-4-arsinic acid, 1-amino-, and 1:6-*di*amino-, 6-acetyl derivative (STICKINGS), 3133.
Benzoxazolonearsinic acid, and amino-, and their acetyl derivatives, and nitro- (BALABAN), 3071.
Benzoyl chloride, interaction of diazomethane and (BRADLEY and ROBINSON), 1310.
Benzoylacetic acid, *p*-chloro-, ethyl ester (BURTON and INGOLD), 919.
Benzoylacetonitrile, combination of, with organic bases in presence of salicylaldehyde (KRISHNAMURTI), 415.
2-Benzoyl-1-acetylalizarin (PERKIN and STOREY), 239.
Benzoylalanine, *p*-nitro-, resolution of, and its salts and ethyl ester (COLLES and GIBSON), 99.
1-Benzoylalizarin 2-methyl ether (PERKIN and STOREY), 239.
2-Benzoylbenzophenone-2′-carboxylic acid, and its derivatives (COOK), 62.
Benzoylbenzoyloxyacetic acid, ethyl ester (BRADLEY and ROBINSON), 1548.
Benzoylcamphor, stable and labile, physical properties of (LOWRY, MACCONKEY, and BURGESS), 1333.
ω-Benzoyloxy-4-benzyloxy-3:5-dimethoxyacetophenone (BRADLEY and ROBINSON), 1557.
2-Benzoyloxy-4:6-dimethoxybenzaldehyde (ROBERTSON, ROBINSON, and STRUTHERS), 1457.
5-Benzoyloxy-4′-methoxyflavylium chloride, 7-hydroxy- (ROBERTSON, ROBINSON, and STRUTHERS), 1458.
***o*-Benzoylphenylacetoxyphthalide** (COOK), 62.
2-Benzoyl-2-phenyl-1:3-dithian (CHIVERS and SMILES), 701.
***O*-Benzoylphloroglucinaldehyde**, preparation and constitution of (ROBERTSON, ROBINSON, and STRUTHERS), 1455.
Benzthiazoles, amino- (HUNTER and STYLES), 3019.
1:2:3-Benztriazole, 1-hydroxy-, and its derivatives (BRADY and REYNOLDS), 196.
Benzyl chlorides, *m*- and *p*-nitro-, velocity of reaction of trimethylamine with (NORRISH and SMITH), 130.
cyanide, 3:4-*di*amino-, and 3-nitro-4-amino-, formyl derivatives (PHILLIPS), 2396.
fluoride, preparation and properties of, and *p*-nitro- (C. K. and E. H. INGOLD), 2249.
phenyl ether, rearrangement of (SHORT), 528.
ω-Benzylacetophenone, ω-bromo- (STEVENS, CREIGHTON, GORDON, and MACNICOL), 3197.
Benzylaniline, nitration of (REILLY, MOORE, and DRUMM), 563.
9-Benzylanthracene, 2-chloro- and 2-chloro-10-bromo-, and its dibromide (BARNETT and WILTSHIRE), 1824.
chloro-, chlorobromo-, and chlorohydroxy-, and their acetyl derivatives (COOK), 2806.

9-Benzylanthracene-ω-pyridinium bromide, 4-chloro- (COOK), 2809.
9-Benzylanthrone, 1:5-*di*chloro- (BARNETT and COOK), 571.
Benzylbenzoylacetic acid, *p*-chloro-, ethyl ester (BURTON and INGOLD), 919.
9-Benzyl-10-benzylidene-9:10-dihydroanthracene, 1:5-*di*chloro- (BARNETT and COOK), 570.
Benzyl-*p*-chlorobenzoylacetic acid, ethyl ester (BURTON and INGOLD), 920.
9-Benzyl-9:10-dihydroanthracene, 1-chloro-9-hydroxy- (COOK), 2806.
9-Benzyl-9:10-dihydroanthranol, 1:5-*di*chloro- (BARNETT and COOK), 572.
Benzylideneanthrone *di*bromide, action of moist silver oxide on (COOK), 58.
Benzylidene-*p*-bromoaniline, *m*-nitro- (NISBET), 3123.
9-Benzylidene-9:10-dihydroanthracene, 1-chloro-10-bromo- and 1-chloro-10-hydroxy-, and its acetyl derivative (COOK), 2806.
1:5-*di*chloro-10-hydroxy-, prototropic rearrangement of (COOK), 2804.
Benzylidenehydroxydihydrothebainone (GULLAND), 704.
Benzylidene-*m*-nitroaniline hydrochloride (FLÜRSCHEIM and HOLMES), 2241.
Benzylidenephenylacetylacetophenone, *o*-hydroxy- (LOVETT and ROBERTS), 1977.
2-Benzylidene-3-phenyl-Δ³-benzopyran (DICKINSON, HEILBRON, and O'BRIEN), 2080.
2-Benzylidene-3-phenyl-Δ³-β-naphthapyran (DICKINSON, HEILBRON, and O'BRIEN), 2081.
Benzylidenethebainol (GULLAND), 706.
Benzylidenethebainone, and its methiodide (GULLAND), 704.
9-Benzyl-10-methylene-9:10-dihydroanthracene, 1:5-*di*chloro- (BARNETT and COOK), 570.
Benzylmethylglyoxal, absorption spectra of enolic and ketonic forms of (LOWRY, MOUREU, and MACCONKEY), 3167.
Benzylmethylsulphone, parachor for (FREIMAN and SUGDEN), 267.
9-Benzyl-10-phenylanthracene, 1:5-*di*chloro-, ω-bromo- and ω-hydroxy-derivatives (COOK), 2805.
2-Benzyl-3-phenylquinoxaline, 2-*p*-chloro- (BENNETT and WILLIS), 1967.
9-Benzyl-10-*iso*propylanthracene, 1:5-*di*chloro- (BARNETT and COOK), 570.
2-Benzylquinoxaline (BENNETT and WILLIS), 1966.
***O*-Benzylsyringic acid,** and its derivatives (BRADLEY and ROBINSON), 1554.
***O*-Benzylsyringoylacetic acid,** ethyl ester, and its copper derivative (BRADLEY and ROBINSON), 1557.
***O*-Benzylsyringoylacetoacetic acid,** ethyl ester (BRADLEY and ROBINSON), 1556.
***O*-Benzylsyringoylcarbinol** (BRADLEY and ROBINSON), 1560.
Benzylthebainones, and their derivatives (GULLAND), 705.
Benzyl-*p*-toluoylacetic acid, ethyl ester, and its oxime (BURTON and INGOLD), 920.
Benzyltrimethylarsonium picrate, and *p*-nitro- (INGOLD, SHAW, and WILSON), 1283.
Benzyltrimethylphosphonium picrate, and nitro- (INGOLD, SHAW, and WILSON), 1288.
2:2'-Bis(10-bromo-5:10-dihydrophenarsazine) (GIBSON and JOHNSON), 2210.
Bis-*p*-bromo-αγ-diphenylpropenyl ether (SHOPPEE), 2570.
Bis-βγ-*di*bromo-αγ-diphenylpropyl ether (SHOPPEE), 2570.
2:2'-Bis(10-bromo-8-methyl-5:10-dihydrophenarsazine) (GIBSON and JOHNSON), 2211.
Bis-2'-carboxyphenylthiol-2:4-*di*hydroxybenzene (PRICE and SMILES), 2863.
2:2'-Bis(10-chloro-5:10-dihydrophenarsazine) (GIBSON and JOHNSON), 2208.
2:4-Bis*di*chloromethyl-1:3-benzdioxin, 6-amino-, and its hydrochloride and acetyl derivative, 6-bromo-, and 6-*mono*- and 6:8-*di*-nitro- (CHATTAWAY and MORRIS), 3243.
2:4-Bis*tri*chloromethyl-1:3-benzdioxin, 6-amino- and 7-bromo-6-amino-, and its acetyl derivative (CHATTAWAY and CALVET), 1090.
5:7-*di*chloro-6-hydroxy-, and its acetyl derivative (CHATTAWAY and CALVET), 2918.
2:4-Bis*di*chloromethyl-1:3-benzdioxin-6-diazonium *per*bromide (CHATTAWAY and MORRIS), 3245.
2:4-Bis*di*chloromethyl-1:3-benzdioxin-6-sulphonic acid, and its ammonium salt and derivatives (CHATTAWAY and MORRIS), 3245.
2:2'-Bis(10-chloro-8-methyl-5:10-dihydrophenarsazine) (GIBSON and JOHNSON), 2210.
2:4-Bis*di*chloromethylene-1:3-benzdioxin, 6-amino- (CHATTAWAY and CALVET), 1091.
5:7-*di*chloro-6-hydroxy- (CHATTAWAY and CALVET), 2918.

Bisdiethylammonium molybdenyl *penta*chloride (JAMES and WARDLAW), 2737.
Bis-αγ-diphenoxy*iso*propyl phosphate (BOYD and LADHAMS), 220.
Bis-αγ-diphenylallyl ether (SHOPPEE), 2569.
4:4-Bis(diphenylamine-2′-arsinic acid) (GIBSON and JOHNSON), 2208.
Bis-αγ-diphenylpropenyl ether (SHOPPEE), 2570.
Bis-αγ-di-*p*-tolyloxy*iso*propyl phosphate (BOYD and LADHAMS), 219.
2:2′-Bis(10-iodo-8-methyl-5:10-dihydrophenarsazine) (GIBSON and JOHNSON), 2211.
Bis-(4-methoxystyryl nonyl ketone) (HEILBRON and IRVING), 2324.
Bis-(3:4-methylenedioxystyryl nonyl ketone) (HEILBRON and IRVING), 2325.
2:2′-Bis(8-methylphenarsazinic acid), and its sodium salt (GIBSON and JOHNSON), 2210.
αβ-Bis-2:4-*di*nitrophenyl-αβ-*di*cyanosuccinic acid, ethyl ester (FAIRBOURNE and FAWSON), 1079.
2:2-Bis(phenarsazinic acid), and its salts (GIBSON and JOHNSON), 2209.
"Bisthiohydantoins," constitution of (STEPHEN and WILSON), 2826.
Bleaching powder, composition of (KINGZETT), 528.
Boron, atomic weight of (COUSEN and TURNER), 2654.
parachor of (ETRIDGE and SUGDEN), 989.
Boron *tri*oxide, density of glasses of (COUSEN and TURNER), 2654.
Boron organic compounds:—
Boric acid, esters, preparation of (ETRIDGE and SUGDEN), 989.
Brazilin, and its derivatives, synthesis of (PERKIN, RÂY, and ROBINSON), 1504.
Bromination, comparison of chlorination with (WATSON and ROBERTS), 2779.
Bromine, effect of intensity of light on photochemical combination of hydrogen and (BRIERS and CHAPMAN), 1802.
vapour, Budde effect in mixtures of air and (BROWN and CHAPMAN), 560.
action of, on acetic anhydride (WATSON and ROBERTS), 2779.
action of, on aliphatic acids (WATSON), 1137.
action of, on strontium oxide, and its hydrates (DUNNICLIFF, SURI, and MALHOTRA), 3106.
addition of, to ethylenic compounds in non-hydroxylic solvents (WILLIAMS and JAMES), 343.
Bromine water, action of, on olefinic acids (READ and REID), 745.
Brucine, constitution of (FAWCETT, PERKIN, and ROBINSON), 3082.
Budde effect in mixtures of air and bromine vapour (BROWN and CHAPMAN), 560.
Buffer mixtures, dilution and neutral salt errors of (MORTON), 1401.
Bulbocapnine methyl ether, synthesis of, and its derivatives (GULLAND and HAWORTH), 1132.
Butadiene *di*bromides, isomeric (FARMER, LAWRENCE, and THORPE), 729.
***n*-Butoxyacetic acid**, and its *l*-menthyl ester (RULE, HAY, and PAUL), 1356.
***p-iso*Butoxybenzoic acid**, preparation of (BRADFIELD and JONES), 3081.
***tert.*-Butylbenzene**, amino-, bromo-, bromoamino-, iodo-, nitro-, and nitroamino-derivatives (SHOESMITH and MACKIE), 2336.
***o-tert.*-Butylbenzoic acid** (SHOESMITH and MACKIE), 2339.
α-*n*-Butyl-Δ^1-*cyclo*hexenylcyanoacetic acid, ethyl ester (MCRAE and MANSKE), 486.
α-*n*-Butyl-Δ^β-nonenoic acid, α-cyano-, ethyl ester (MCRAE and MANSKE), 487.

C.

Cadmium hydroxyhyponitrite and hyponitrite (NEOGI and NANDI), 1453.
Cæsium hyponitrite (NEOGI and NANDI), 1452.
Calcium hyponitrite (NEOGI and NANDI), 1453.
Callistephin chloride, constitution of (ROBERTSON and ROBINSON), 1460.
Camphoranilic acids, bromo- and iodo- (SINGH, AHUJA, and LAL), 2410.
Camphoric anhydride, action of substituted aromatic amines on (SINGH, AHUJA, and LAL), 2410.
Camphoro-*p*-bromophenylimide (SINGH, AHUJA, and LAL), 2413.
Camphoroiodophenylimides (SINGH, AHUJA, and LAL), 2410.
***d*-Camphorsulphonic acid**, triethylenediaminenickel salt (BUCKNALL and WARDLAW), 2742.
Campnospermonol, and its derivatives (JONES and SMITH), 65.
Campnospermum brevipetiolatum, oily exudate from (JONES and SMITH), 65.
Carane, hydroxychloro- (PILLAY and SIMONSEN), 364.
5-Carbamido-2-hydroxyphenylarsinic acid (STICKINGS), 3133.
***p*-Carbamidophenylarsinic acid** (STICKINGS), 3133.

Carbazole-1-carboxylic acid (BRISCOE and PLANT), 1990.
3-Carbethoxyamino-5-acetamido-4-hydroxyphenylarsinic acid, 3-ω-chloro- (NEWBERY, PHILLIPS, and STICKINGS), 3064.
3-Carbethoxyamino-4-hydroxyphenylarsinic acid, 3-ω-chloro- (NEWBERY, PHILLIPS, and STICKINGS), 3063.
4-*p*-Carbethoxybenzeneazo-5-hydroxy-2:2:3:3-tetramethyl-Δ⁴-*cyclo*pentenone (SHOPPEE), 2364.
***p*-Carbethoxybenzylmalonic acid, and chloro-, ethyl esters** (TITLEY), 2581.
***m*-Carbethoxybenzylmethylmalonic acid, ethyl ester** (TITLEY), 2582.
γ-Carbethoxy-*n*-hexylaminopropylarsinic acid (GOUGH and KING), 2443.
γ-*o*-Carbethoxyphenyl-*n*-butyric acid, ethyl ester (TITLEY), 2577.
3-*o*-Carbethoxyphenylmethylcarbamyl-1:2-dimethyl-4-quinolone, and 6-bromo-3-*p*-bromo- (HEILBRON, HOLT, and KITCHEN), 937, 941.
***o*-Carbethoxyphenylmethylcarbamyl-2-methylquinoline, 4-chloro-6-bromo-3-*p*-bromo-, methochloride** (HEILBRON, HOLT, and KITCHEN), 941.
4-chloro-, metho-salts (HEILBRON, HOLT, and KITCHEN), 938.
γ-3-Carbethoxypiperidinopropylarsinic acid (GOUGH and KING), 2445.
Carbocyanine dyes (HAMER), 3160.
Carbohydrazide, reactions of (MUNRO and WILSON), 1257.
3-*o*-Carbomethoxyphenylmethylcarbamyl-1:2-dimethyl-4-quinolone (HEILBRON, HOLT, and KITCHEN), 937.
3-*o*-Carbomethoxyphenylmethylcarbamyl-2-methylquinoline, 4-chloro-, salts (HEILBRON, HOLT, and KITCHEN), 939.
Carbon chains, alternating effect in (INGOLD and VASS), 417, 2262; (BAKER, COOPER, and INGOLD), 426; (INGOLD and ROTHSTEIN), 1207, 1278; (INGOLD, SHAW, and WILSON), 1280; (C. K. and E. H. INGOLD), 2249.
hydrosols, preparation of (CHIRNOAGA), 298.
Carbon *mon*oxide, decomposition of, in the corona discharge (OTT), 1378.
inflammation of mixtures of air and (MAXWELL and WHEELER), 15.
effect of catalysts on flame speed, infra-red emission and ionisation during combustion of oxygen and (GARNER and JOHNSON), 280.
***di*sulphide, ignition of** (WHITE), 751.
action of acetylene with (BRISCOE, PEEL, and ROBINSON), 2857.
Carbon:—
Carbonic acid, *tri-* and *tetra*-thio- (MILLS and ROBINSON), 2330.
Carbonyl compounds, thermodynamic stability of cyanohydrins of (LAPWORTH and MANSKE), 2533.
αβ-unsaturated, reactivity of the double bonds in (SESHADRI), 166.
***o*-Carboxybenzaldehyde *p*-nitrophenylhydrazone** (ROWE and LEVIN), 2555.
***o*-Carboxybenzenesulphinic acid, *p*-nitrobenzyl ester** (PRICE and SMILES), 2861.
8-Carboxy-1.4-benz*iso*oxazine-6-arsinic acid, 3-hydroxy- (NEWBERY, PHILLIPS, and STICKINGS), 3062.
***p*-Carboxybenzylmalonic acid** (TITLEY), 2581.
***p*-Carboxycinnamic acid, and its ethyl ester** (TITLEY), 2581.
4(5)-Carboxy-1:3-dimethylglyoxalinium picrate (HUBBALL and PYMAN), 31.
2′-Carboxydiphenyl sulphoxide, 2:4-*di*hydroxy- (PRICE and SMILES), 3157.
4-Carboxydiphenyl selenide and its dibromide, and selenoxide, and its salts (GAYTHWAITE, KENYON, and PHILLIPS), 2280.
1-Carboxy*cyclo*heptane-1-acetic acid, preparation of, and its derivatives (VOGEL), 2025.
4-Carboxy-2′:4′:6′:2″:4″:6″-hexamethoxytriphenylcarbinol, acetate of, and its perchlorate (LUND), 1573.
2-Carboxy-4′-hydroxydiphenyl sulphide (PRICE and SMILES), 2862.
2-Carboxy-2′:4′-*di*hydroxydiphenyl sulphide (PRICE and SMILES), 2862.
5-Carboxy-2-methoxy-1-αββ-*tetra*chloroethylbenzene (CHATTAWAY and CALVET), 2915.
5-Carboxy-2-methoxy-1-ββ-*tri*chloro-α-hydroxyethylbenzene (CHATTAWAY and CALVET), 2915.
5-Carboxy-2-methoxyphenylglyoxylic acid, and its phenylhydrazone (CHATTAWAY and CALVET), 2917.
5-Carboxy-1-methylglyoxaline picrate (HUBBALL and PYMAN), 28.
1-Carboxy*cyclo*pentane-1-acetic acid, and its derivatives (VOGEL), 2022.
α-Carboxypentane-γδ-dione. See **γδ-Diketohexoic acid.**
***m*-Carboxyphenyl ethyl sulphide *di*bromide** (HOLLOWAY, KENYON, and PHILLIPS), 3004.
ethyl sulphoxide, preparation and resolution of (HOLLOWAY, KENYON, and PHILLIPS), 3003.
***p*-Carboxyphenyl methyl selenide and selenoxide, and their salts** (GAYTHWAITE, KENYON, and PHILLIPS), 2280.

9-*o*-Carboxyphenylanthracene (Cook), 64.
9-*o*-Carboxyphenylanthrone (Cook), 63.
5-Carboxyphenylarsinic acid, 3-amino-4-hydroxy-, and its acetyl derivative, and 3-nitro-4-hydroxy- (Newbery, Phillips, and Stickings), 3062.
β-*o*-Carboxyphenyl*iso*butyric acid (Titley), 2577.
β-*m*-Carboxyphenyl*iso*butyric acid, and its methyl ester (Titley), 2582.
dl-*m*-Carboxyphenylethylsulphine-*p*-toluenesulphonylimine, preparation and resolution of (Holloway, Kenyon, and Phillips), 3004.
m-Carboxyphenylethylsulphone (Holloway, Kenyon, and Phillips), 3004.
9-*o*-Carboxylphenyl-9-hydroxyanthrone, spirocyclic lactone of (Cook), 63.
o-Carboxyphenyl 2-hydroxy-α-naphthyl sulphide (Price and Smiles), 2863.
γ-*o*-Carboxyphenyl-α-methylbutyric acid (Titley), 2578.
3-*o*-Carboxyphenylmethylcarbamyl-1:2-dimethyl-4-quinolone (Heilbron, Holt, and Kitchen), 937.
Carboxyphenyl-*p*-nitrobenzylsulphones, and their *p*-nitrobenzyl esters (Price and Smiles), 2861.
β-*o*-Carboxyphenylpropionic acid, and its ethyl ester (Titley), 2575.
Carboxyphenylpropionic acids, and their methyl esters (Titley), 2581.
d-Δ^3-Carene, oxidation of (Pillay and Simonsen), 361.
d-Carene-β-glycol, and its hydrogen phthalate (Pillay and Simonsen), 362.
l-Carene oxide, and its semicarbazone (Pillay and Simonsen), 363.
Caronic acid, methyl ester, and its reduction (Hariharan, Menon, and Simonsen), 438.
Carvacrolaldehydes, synthesis of (Bell and Henry), 2221.
Caryophyllene, reaction for detection of (Gibson), 750.
nitrosite, rotation dispersion and circular dichroism of (Mitchell), 3258.
Catalysis, acid and salt effects in (Dawson and Key), 543, 1239, 1248, 2154; (Dawson and Lowson), 2146, 3218; (Dawson, Hall, and Key), 2844.
Catalysts, postulated, determination of mean life of (Briers and Chapman), 1802.
Catalytic hydrogenation of cyclic compounds (Sadikov and Mikhailov), 438.
unsaturated compounds (Lebedev and Yakubchik), 828, 2190.
Catechylthymylacetonitrile (Bell and Henry), 2226.
Cathodes, antimony, electrolysis with (Grant), 1987.
Cells, electrochemical, Haber's glass (Hughes), 491.
silver nitrate, in acetonitrile and benzonitrile (Koch), 524.
Cellulose, cotton, velocity of acid hydrolysis of (Hunter), 2643.
Cerium *di*oxide, mixed catalysts of thoria and (Goggs), 2667.
Charcoal, heat of adsorption of oxygen on (McKie), 2870.
animal, adsorption of organic acids on (Griffin, Richardson, and Robertson), 2705.
Chemical constitution. See Constitution, chemical.
reactions. See under Reactions.
Chloral, condensations of, with anisic acid, *p*-nitroanisole and 2:6-dichloroquinol (Chattaway and Calvet), 2913.
action of, on halogen-substituted phenylhydrazines (Chattaway and Daldy), 2756.
condensation of, with substituted phenols (Chattaway and Calvet), 1088.
2:4:6-trichlorophenylhydrazones of (Chattaway and Daldy), 2759.
Chlorination, comparison of bromination with (Watson and Roberts), 2779.
Chlorine, photochemical combination of hydrogen and, in glass capillary tubes (Chapman and Grigg), 3233.
Hydrochloric acid, densities and viscosities of mixtures of lithium chloride and (Ingham), 2381.
catalytic activity of, in hydrolysis of ethyl acetate (Dawson and Lowson), 2146.
reactions of, with selenium and tellurium dioxides (Parker and Robinson), 2853.
Chloroamines as halogenation agents (Bradfield, Orton, and Roberts), 782.
ψ-Cholestene, formation of, from dry distillation of cholesterol (Heilbron and Sexton), 347.
Cholestenone, formation of, from dry distillation of cholesterol (Heilbron and Sexton), 347.
preparation of (Sexton), 2825.
Cholesterol, dry distillation of (Heilbron and Sexton), 347.
derivatives, absorption spectra of (Heilbron, Morton, and Sexton), 47.

Chromium, parachor for (FREIMAN and SUGDEN), 264.
Chromium salts, action of fluorine on aqueous solutions of (FICHTER and BRUNNER), 1862.
Chromyl chloride, parachor for (FREIMAN and SUGDEN), 268.
Chromic acid, second dissociation constant of (HUGHES), 502.
apparatus for oxidation with (SHORT), 2630.
Cinnamic acid, addition of mixtures of bromine and chlorine to, and its derivatives (HANSON and JAMES), 1955.
Cinnamic acid, chlorobromo- (HANSON and JAMES), 2983.
Cinnamyl alcohol, *p*-chloro-, and its bromide and *p*-nitrobenzoate (BURTON), 1655.
Coal, composition of (HOLROYD and WHEELER), 2669, 3197.
rational analysis of (FRANCIS and WHEELER), 2967.
Cobalt bases (*cobaltammines*):—
Selenitopentamminecobalt salts (RILEY), 2985.
Cobalt sulphate, equilibrium of, with potassium sulphate and water (CAVEN and JOHNSTON), 2506.
Cobalt organic compounds:—
Cobalt allylamines (BUCKNALL and WARDLAW), 2648.
Coke, determination of volatile matter in (EATON and PEXTON), 1215.
Colour and constitution (HODGSON and HANDLEY), 162, 1882.
Colouring matters. See Genistein.
Combustion, slow, autoxidation during (MARDLES), 872.
Compounds, conjugated, properties of (FARMER, LAWRENCE, and THORPE), 729; (EVANS and FARMER), 1644.
Constitution, chemical, and rotatory power (GERRARD and KENYON), 2562; (HOLLOWAY, KENYON, and PHILLIPS), 3000.
and the parachor (FREIMAN and SUGDEN), 263; (SUGDEN), 410; (ETRIDGE and SUGDEN), 989.
and adsorption (GRIFFIN, RICHARDSON, and ROBERTSON), 2705.
and colour (HODGSON and HANDLEY), 162, 1882.
and trypanocidal action (GOUGH and KING), 2426.
Co-ordination and residual affinity (MORGAN and BURSTALL), 143; (MORGAN and CASTELL), 3252.
Copper hydrosols, conductivity of (MURRAY), 1235.
Copper:—
Cupric bromide, solubility of, in aqueous and hydrobromic acid solutions (CARTER and MEGSON), 2954.
sulphate, hydrolysis of (HUGHES), 503.
Cuprous chloride, interaction of potassium chromate and dichromate with, in sodium chloride solution (VENN and EDGE), 2142.
hydride, action of, on diazonium salts (NEOGI and MITRA), 1332.
Corytuberine dimethyl ether (GULLAND and HAWORTH), 1834.
*iso***Coumarin**, 3-chloro- (DAVIES and POOLE), 1618.
Coumarins, reactivity of the double bond in (SESHADRI), 166.
m-**Cresol**, influence of electrolytes on solubility of, in water (CARTER and HARDY), 127.
Cresols, equilibria of amines with (PUSHIN and SLADOVIĆ), 2474.
Crotylideneacetone, hydrogenation of (EVANS and FARMER), 1647.
Cryoscopy with dibenzyl ether (BENNETT and WILLIS), 2305.
with phenols (RICHARDSON and ROBERTSON), 1775.
l-*α*- and -*β*-**Curcumenes**, with their derivatives (RAO and SIMONSEN), 2496.
Cyanidin chloride, synthesis of, and its benzoyl derivative (ROBERTSON and ROBINSON), 1526.
*apo***Cyanines**, constitution of (MILLS and ORDISH), 81.
ψ-**Cyanine condensation** (HAMER), 206.
Cyanine dyes (MILLS and ORDISH), 81.
*iso***Cyanine dye** (HEILBRON, HOLT, and KITCHEN), 934.
Cyanogen:—
Hydrocyanic acid, and its alleged isomerides, and its methyl ester, mercuric derivative (COATES, HINKEL, and ANGEL), 540.
cuprous salt, action of methyl iodide on (HARTLEY), 780.
Cyanoplatinates, structure of (TERREY), 202.
Cyclic compounds, synthesis of (VOGEL), 1013, 2010, 2032.
catalytic hydrogenation of (SADIKOV and MIKHAILOV), 438.
Cylinders, closed, explosions in (KIRKBY and WHEELER), 3203; (ELLIS and WHEELER), 3215.

D.

r-trans-**Decahydro-β-naphthylcyanoacetic acid**, ethyl ester (VOGEL), 2026.

trans-**Decahydro-β-naphthylidenecyanoacetic acid**, ethyl ester (VOGEL), 2026.
trans-**Decahydro-β-naphthylmalonic acid** (VOGEL), 2027.
Decane-1:10-dicarboxylic acid, methyl hydrogen ester (BHATTACHARYA, SALETORE, and SIMONSEN), 2679.
Demethylpyropseudaconine (SHARP), 3099.
Densi-tensimeter (SMITS), 2409.
Density of liquids, determination of (GRINDLEY), 3297.
Deoxylupanine, and its derivatives (CLEMO and LEITCH), 1818.
Deoxytrimethylbrazilone, preparation of, and its bromides (PERKIN, RÂY, and ROBINSON), 1508.
r-, *d*- and *l*-**Desylamine** hydrochlorides (MCKENZIE and WALKER), 650.
r- and *l*-**Desylphthalamic acids** (MCKENZIE and WALKER), 648.
2:2′-Diacetmethylamidodiphenyl *di*selenide (CLARK), 2317.
ββ-Diacetoxyethyl ether (MACLEOD), 3092.
Diacetylanthrapurpurins, and their methyl ethers (PERKIN and STOREY), 235.
Diacetylphenylenediamines, amino- (PHILLIPS), 175.
Diacetyltartaric acid, and its esters, rotatory dispersion of (AUSTIN), 1825.
ethyl ester (FINDLAY and CAMPBELL), 1772.
Dialkylsulphones, decomposition of (FENTON and INGOLD), 3127.
Diamminenickelosalicylic acid, methyl ester (DOAK and PALMER), 2769.
Dianhydro-6-aminopiperonaldihydrocodeinone, and its methiodide (GULLAND), 703.
Diaryloxy*iso*propyl alcohols, action of phosphoryl chloride on, in pyridine (BOYD and LADHAMS), 215.
Diazenes, reactions of (BRADLEY and ROBINSON), 1310.
Diazoacetophenone (BRADLEY and ROBINSON), 1317.
ω-Diazo-4-benzyloxy-3:5-dimethoxyacetophenone (BRADLEY and ROBINSON), 1559.
ω-Diazo-3:4-diacetoxyacetophenone (BRADLEY and SCHWARZENBACH), 2907.
Diazomethane, acylation of (BRADLEY and SCHWARZENBACH), 2904.
interaction of benzoyl chloride and (BRADLEY and ROBINSON), 1310.
ω-Diazo-*p*-nitroacetophenone (BRADLEY and SCHWARZENBACH), 2907.
Diazonium salts, action of cuprous hydride on (NEOGI and MITRA), 1332.
Diazo-salts, action of, on aromatic sulphonamides (KEY and DUTT), 2035.
1-Dibenzenesulphonamido-8-nitronaphthalene (MILLS and ELLIOTT), 1299.
Dibenzoyltartaric acid, esters (FINDLAY and CAMPBELL), 1773.
Dibenzyl ether as a cryoscopic solvent (BENNETT and WILLIS), 2305.
10:10-Dibenzylanthrone, 1-chloro-(BARNETT and COOK), 572.
9:10-Dibenzyl-9:10-dihydroanthranol, 1:5-*di*chloro- (BARNETT and COOK), 569.
Dibenzylethyl-*n*-butylstannane (KIPPING), 2372.
Dibenzyl ketone, anhydropyrylium bases and *spiro*pyrans from (DICKINSON, HEILBRON, and O'BRIEN), 2077.
9:9-Dibenzyl-10-methyl-9:10-dihydroanthranol (BARNETT and COOK), 571.
***l*-Dibenzyl-2-pyrrolidone-5-carboxyanilide** (GRAY), 1266.
Dibenzylsilicon *di*chloride, action of sodium on (STEELE and KIPPING), 1431.
Di(*O*-benzylsyringoyl)succinic acid, ethyl ester (BRADLEY and ROBINSON), 1558.
1:3-Dibenzylthiolbenzene *di*sulphoxides (BELL and BENNETT), 3192.
Dibenzylthiolethane *di*sulphoxides (BELL and BENNETT), 3191.
***NN′*-Dicarbethoxybenzidines**, *mono*- and *di*-nitro- (LE FÈVRE and TURNER), 252.
***NN′*-Di-*o*-carbethoxybenzoylbenzidine** (LE FÈVRE and TURNER), 251.
3:3′-Di(*o*-carbethoxyphenylmethylcarbamyl)-1:2:1′-trimethyl*iso*cyanine, 4′-chloro-, salts (HEILBRON, HOLT, and KITCHEN), 940.
1:2-Dicarbomethoxy-3-methyl*cyclo*propane-3-cyanoacetic acid, methyl ester (GOSS and INGOLD), 1273.
2:2′-Dicarboxymethylthioldiphenyl (BARBER and SMILES), 1146.
4:4′-Dicarboxyphenyl *di*selenide (GAYTHWAITE, KENYON, and PHILLIPS), 2286.
Dicarvacrylacetonitrile, and its acetyl derivative (BELL and HENRY), 2224.
***NN′*-Dicinnamoylbenzidine** (LE FÈVRE and TURNER), 251.
2:3-Di(3:4-dimethoxystyryl)-6-methylquinoxaline (BENNETT and WILLIS), 1971.
2-3-Di(3:4-dimethoxystyryl)quinoxaline (BENNETT and WILLIS), 1969.
Diethyl sulphide, ββ′-*di*chloro-, chlorination products of (MUMFORD and PHILLIPS), 155.
telluride, isomeric derivatives of (GILBERT and LOWRY), 3179.

3:3′-Diethylamino-4:4′-*di*hydroxyarsenobenzene, 5:5′-*di*amino-3:3′-*di*-β-hydroxy-, diacetyl derivative (Newbery, Phillips, and Stickings), 3064.
1:1′-Diethyl-5:6(or 5′:6′)-benz-ψ-cyanine iodide (Hamer), 212.
ββ-Diethylbutyrolactone, and its silver salt (Sircar), 901.
Diethylcarbonatoalizarin (Perkin and Storey), 240.
Diethylcarbonatoanthragallols, and their methyl ethers (Perkin and Storey), 242.
2:7-Diethylcarbonatoanthrapurpurin, and its 1-methyl ether (Perkin and Storey), 236.
1:1′-Diethyl*iso*cyanine iodide (Hamer), 213.
Diethylene oxide, acetylation of (Macleod), 3092.
1:1′-Diethyl-ψ-cyanine iodide (Hamer), 212.
4:4′-Diethyloxamidodiphenyl (Le Fèvre and Turner), 251.
2:2′-Diethylselenocarbocyanine iodide (Clark), 2319.
Diethyltellurone (Gilbert and Lowry), 3182.
α-Diethyltelluronium halides (Gilbert and Lowry), 3181.
1′:2-Diethylthio-ψ-cyanine iodide (Hamer), 213.
ββ-Diethylvalerolactone, and its silver salt (Sircar), 903.
2:3-Di(β-furylvinyl)quinoxaline (Bennett and Willis), 1969.
Dihydroaromadendrene (Briggs and Short), 2527.
2:3-Dihydro-1:4-benz*iso*oxazine-6-arsenoxide (Newbery, Phillips, and Stickings), 3064.
2:3-Dihydro-1:4-benz*iso*oxazine-6-arsinic acid (Newbery, Phillips, and Stickings), 3063.
3:4-Dihydro*iso*coumarin, 3:3:4:4-*tetra*chloro- (Davies and Poole), 1619.
3:4-Dihydrocoumarin-4-acetic acid, and 6-nitro- (Seshadri), 169.
3:4-Dihydrocoumarin-4-carbamylacetic acid, 6-amino-, and its hydrochloride (Seshadri), 172.
3:4-Dihydrocoumarin-4-cyanoacetamide, and 6-amino-, and its benzoyl derivative and 6-nitro- (Seshadri), 168.
3:4-Dihydrocoumarin-4-cyanoacetic acid (Seshadri), 168.
l-Dihydro-α-curcumenylamine, and its acetyl derivative (Rao and Simonsen), 2502.
l-Dihydro-α-curcumenyltrimethyl ammonium hydroxide and iodide (Rao and Simonsen), 2503.
Dihydrodeoxytrimethylbrazilone (Perkin, Rây, and Robinson), 1510.
Dihydro*iso*indole, sulphonyl derivatives of (Fenton and Ingold), 3295.
5:10-Dihydrophenarsazine, 10-chloro-, and its derivatives (Gibson and Johnson), 2204.
Dihydro*iso*safrole, β-amino-α-hydroxy-, and its hydrochloride (Read and Reid), 1491.
2:4-Diketo-5-ethyltetrahydrothiazole, 3-amino-, 2-hydrazone, and its dibenzylidene derivative (Stephen and Wilson), 1419.
2:4-Diketo-5-ethyltetrahydrothiazole-2-ketazine (Stephen and Wilson), 2827.
γδ-Diketohexoic acid γ-phenylhydrazone, and its sodium salt (Clemo and Welch), 2627.
2:4-Diketo-5-methyltetrahydrothiazole, 3-amino-, 2-hydrazone, and its dibenzylidene derivative (Stephen and Wilson), 1418.
2:4-Diketo-5-methyltetrahydrothiazole-2-ketazine (Stephen and Wilson), 2827.
1:2-Diketones, absorption spectra of isomeric (Lowry, Moureu, and MacConkey), 3167.
1:3-Diketones, relative reactivity of methylene groups in (Lovett and Roberts), 1975
1:4-Diketo-3-(3′-nitrophenyl)tetrahydrophthalazine (Rowe, Himmat, and Levin), 2563.
1:4-Diketo-3-(4′-nitrophenyl)tetrahydrophthalazine (Rowe and Levin), 2554.
Diketosuccinanil osazones and *p*-tolylhydrazone (Chattaway and Humphrey), 1097.
Diketosuccinanilic acid phenylosazone (Chattaway and Humphrey), 1097.
Diketosuccinic acid phenylosazone, imide ring derivatives of (Chattaway and Humphrey), 1094.
Diketosuccinimide phenylosazone (Chattaway and Humphrey), 1096.
Diketosuccinobenzylamic acid phenylosazone, benzylamine salt (Chattaway and Humphrey), 1096.
Diketosuccinobenzylimide phenylosazone (Chattaway and Humphrey), 1096.
Diketosuccinodibenzylamic acid phenylosazone, and its dibenzylamine salt (Chattaway and Humphrey), 1097.
Diketosuccinophenylhydrazide osazones (Chattaway and Humphrey), 1097.

Diketosuccinophenylmethylhydrazide phenylosazone (CHATTAWAY and HUMPHREY), 1097.

2:4-Diketo-1:2:3:4-tetrahydro-1:3-quinazoline-7-arsinic acid (STICKINGS), 3134.

2:4-Diketotetrahydrothiazole 2-semicarbazone (STEPHEN and WILSON), 1421.

2:4-Diketotetrahydrothiazole, 3-amino-, 2-hydrazone (STEPHEN and WILSON), 1418.

4:4′-Diketo-1:1′:2′-trimethyl-1′:4′-dihydro-2(3′)-quinolylquinazoline (HEILBRON, HOLT, and KITCHEN), 938.

3:5-Dimethoxyacetophenone, 4-hydroxy-, and its benzyl derivative (BRADLEY and ROBINSON), 1564.

5:6-Dimethoxyaporphine, and its hydrochloride (GULLAND and HAWORTH), 581.

6:7-Dimethoxy-1-benzyl-3:4-dihydro*iso*quinoline, 2′-nitro-, and its derivatives (GULLAND and HAWORTH), 586.

3:4-Dimethoxybenzylidenemalonic acid (JACKSON and KENNER), 1661.

6:7-Dimethoxy-1-benzyl-3-methyltetrahydro*iso*quinoline, 2′-amino-, and its derivatives (GULLAND and HAWORTH), 589.

2′:5′-Dimethoxy-2-benzylquinoxaline, 3-hydroxy- (GULLAND and VIRDEN), 1482.

7:8-Dimethoxycarbostyril (GULLAND and VIRDEN), 932.

2:5-Dimethoxycinnamic acid, α-amino-, benzoyl derivative (GULLAND and VIRDEN), 1481.

3:4-Dimethoxycinnamic acid, 2-amino-, and its hydrochloride and acetyl derivative, and *trans*-2-nitro- (GULLAND and VIRDEN), 932.

6:6′-Dimethoxydiphenic acid, resolution of, and its alkaloid salts and methyl ester (KENNER and TURNER), 2340.

5:5′-Dimethoxydiphenyl sulphides, *di*-nitro- (HODGSON and HANDLEY), 626.

***di*sulphides, *di*amino-,** and their derivatives (HODGSON and HANDLEY), 625.

3:3′-Dimethoxydiphenylglutaric acid, and its derivatives (JACKSON and KENNER), 1661.

5:5′-Dimethoxydiphenylsulphones, *di*-nitro- (HODGSON and HANDLEY), 627.

2:5-Dimethoxydiphenylsulphone-2′-carboxylic acid, and its methyl ester (PRICE and SMILES), 3157.

2:4-Dimethoxy-6-ethylbenzaldehyde (BARGER and SILBERSCHMIDT), 2924.

3:4-Dimethoxy-6-ethylbenzoic acid (BARGER and SILBERSCHMIDT), 2925.

3:4-Dimethoxy-6-ethylbenzylidenehippuric acid, azlactone of (BARGER and SILBERSCHMIDT), 2925.

3:4 Dimethoxy-6-ethylphenylacetic acid (BARGER and SILBERSCHMIDT), 2926.

α-3:4-Dimethoxy-6-ethylphenyl-β-6-nitro-3:4-dimethoxy-β-phenylacrylic acid (BARGER and SILBERSCHMIDT), 2926.

3′:5′-Dimethoxyflavylium chloride, **5:7:4′-*tri*hydroxy-** (BRADLEY and ROBINSON), 1566.

2-(4′:5′-Dimethoxy-2′-β-methylaminoethyl)phenyldihydroindole, and its derivatives (GULLAND and HAWORTH), 589.

2-(4′:5′-Dimethoxy-2′-β-methylaminoethyl)phenylindole, and its derivatives (GULLAND and HAWORTH), 587.

2-(4′:5′-Dimethoxy-2′-β-methylaminoethyl)phenyl-3-oximinoindole (GULLAND and HAWORTH), 588.

3′:4′-Dimethoxy-6:7-methylenedioxy-1-benzyl-3:4-dihydro*iso*quinoline, 2′-nitro-, and its salts (GULLAND and HAWORTH), 1134.

3′:4′-Dimethoxy-6:7-methylenedioxy-1-benzyl-2-methyltetrahydro*iso*quinoline, 2′-amino-, and its dihydrochloride (GULLAND and HAWORTH), 1135.

3:4-Dimethoxy-α-methylhomophthalic anhydride, and 6-bromo- (KOEPFLI and PERKIN), 2998.

5:6-Dimethoxy-3-methyl-1-hydrindone, and its derivatives (KOEPFLI and PERKIN), 2996.

3:8-Dimethoxyphenanthrene-5-carboxylic acid, 4-hydroxy-, lactone (GULLAND and VIRDEN), 928.

3′:4′-Dimethoxyphenylaceto-β-3:4-dimethoxyphenylethylamide, 2′-nitro- (GULLAND and HAWORTH), 1835.

3′:4′-Dimethoxyphenylaceto-β-3-methoxyphenylethylamide, 2′-nitro- (GULLAND and HAWORTH), 2084.

3′:4′-Dimethoxyphenylaceto-β-3:4-methylenedioxyphenylethylamide, 2′-nitro- (GULLAND and HAWORTH), 1134.

β-3:4-Dimethoxyphenylpropane-*aaγ*-tricarboxylic acid, ethyl ester (JACKSON and KENNER), 1661.

2:5-Dimethoxyphenylpyruvic acid (GULLAND and VIRDEN), 1481.

7:4′-Dimethoxy-2-styryl*iso*flavone, 5-hydroxy-, and its acetyl derivative (BAKER and ROBINSON), 3116.

2:3-Di(*p*-methoxystyryl)-6-methylquinoxaline (BENNETT and WILLIS), 1971.

3:4-Dimethoxystyryl nonyl ketone, and its dimeride (HEILBRON and IRVING), 2324.
2:3-Di(methoxystyryl)quinoxalines (BENNETT and WILLIS), 1969.
3:8-Dimethoxythebenidine, and its picrate (GULLAND and VIRDEN), 927.
Dimethoxythioxanthone *di*oxides (PRICE and SMILES), 3158.
ββ-Dimethylacrylic acid, α-cyano-, ethyl ester, synthesis of (VOGEL), 2019.
***p*-Dimethylaminobenzaldehyde**, reduction of (CLEMO and SMITH), 2423.
ω-Dimethylamino-ω-benzylacetophenone, and its derivatives (STEVENS, CREIGHTON, GORDON, and MACNICOL), 3196.
***p*-Dimethylaminobenzyl alcohol**, preparation of, and its derivatives (CLEMO and SMITH), 2423.
β-Dimethylaminoethylarsinic acid, derivatives of (GOUGH and KING), 2435.
***NN'*-Dimethyl-αγ-*di*amino-β-phenylpropane**, and its di-*p*-toluenesulphonyl derivative (JACKSON and KENNER), 1659.
γ-Dimethylaminopropylarsinic acid, salts of (GOUGH and KING), 2441.
Dimethylanilines, bromoamino-, bromo-*mono*- and -*di*-nitro-, chloroamino- and chloronitro-, and their acetyl derivatives (CLEMO and SMITH), 2420.
1-2':4'-Dimethylanilino-1-cyano*cyclo*hexane (BETTS and PLANT), 2073.
1-2':4'-Dimethylanilino*cyclo*hexane-1-carboxylic acid, and its amide (BETTS and PLANT), 2073.
5:5'-Dimethylarsenobenzene, 3:3-*di*amino-4:4'-*di*hydroxy- (NEWBERY, PHILLIPS, and STICKINGS), 3061.
2:2'-Dimethylarsenobenziminazoles (PHILLIPS), 3137.

Diphenacyldimethylpiperazinium *di*bromide (STEVENS, CREIGHTON, GORDON, and MACNICOL), 3196.
αγ-Diphenoxy*iso*propyl phosphate, sodium salt (BOYD and LADHAMS), 219.
Diphenyl, cyclic disulphides from (BARBER and SMILES), 1141.
Diphenyl, *di*amino-, bromoamino- and nitroamino-derivatives, and their acetyl and toluenesulphonyl derivatives (BELL), 2774.
bromoamino-, bromohydroxy-, and bromonitro-derivatives, and their acetyl and benzoyl derivatives (HINKEL and HEY), 1839.
5-bromo-3-hydroxy- and 4:5-*di*bromo-3-hydroxy-, and their benzoyl derivatives (HINKEL and HEY), 1203.
*tri*chloro-, *di*chloroamino-, *di*chloronitro-, and 2:3:5-*tri*chloro-4′-nitro-, and their derivatives (HINKEL and HEY), 2791.
Diphenyl selenide and selenoxide, 4-amino-, and their acetyl derivatives, and their halide salts (GAYTHWAITE, KENYON, and PHILLIPS), 2289.
*di*sulphide, 2:2′-*di*amino-, preparation and derivatives of (CLARK), 2319.
3:3′-*di*amino-4:4′-*di*nitro-, diacetyl derivative (HODGSON and HANDLEY), 164.
di-2-iodo- (BARBER and SMILES), 1144.
2:2′-*di*thiol- (BARBER and SMILES), 1146.
Diphenyl series (LE FÈVRE and TURNER), 245, 963; (HINKEL and HEY), 1838; (BELL), 2770.
αγ-Diphenylallyl bromides (BURTON and INGOLD), 916.
ether, three-carbon prototropy in (SHOPPEE), 2567.
Diphenylamine, *p*-amino-, *N*-acetyl derivative (GIBSON and JOHNSON), 1286.
4′-bromo-2-amino-, and 4′-bromo-2-nitro- (MCCOMBIE, SCARBOROUGH, and WATERS), 356.
Diphenylamine-*p*-arsinic acid (GIBSON and JOHNSON), 1286.
Diphenylamine-2′-carboxylic acid, 2-amino-, and its hydrochloride (MCCOMBIE, SCARBOROUGH, and WATERS), 358.

Diphenylamine-2:4:6-trisulphonanilide (DAVIES and WOOD), 1125.
Diphenylbenzyl-*n*-butylstannane (KIPPING), 2871.
9:9-Diphenyl-10-benzyl-9:10-dihydroanthranol (BARNETT and COOK), 571.
9:9-Diphenyl-10-benzylidene-9:10-dihydroanthracene (BARNETT and COOK), 571.
βγ-Diphenylbutane-ααδδ-tetracarboxylic acid, *r*- and *meso*-ethyl esters, and **αδ-*di*bromo-** (VOGEL), 1013.
Diphenyl-2-carboxylic acid, menthyl ester (BRETSCHER, RULE, and SPENCE), 1502.
Diphenyl-2-carboxylic acid, 2′-cyano-, diethylaminoethyl ester and chloride of (BELL), 3248.
Diphenyl-2- and **-4-carboxylic acids**, diethylaminoethyl esters and derivatives of (BELL), 3247.
3:3′-Diphenyldibenzo*spiro*pyran (DICKINSON, HEILBRON, and O'BRIEN), 2081.
Diphenyl-3:3′-dicarboxylic acid, 5:5′-*di*chloro-, and its salts and methyl ester (MCALISTER and KENNER), 1913.
1:3-Diphenyldihydro*iso*indole, and its derivatives (BOYD and LADHAMS), 2089.
3:3′-Diphenyldi-β-naphtha*spiro*pyran (DICKINSON, HEILBRON, and O'BRIEN), 2082.
Diphenyl-4:4′-disulphinic acid (BARBER and SMILES), 1148.
Diphenyl-3:3′-disulphonyl chloride, 4:4′-*di*chloro- (BARBER and SMILES), 1147.
Diphenylene oxide, halogenonitro- and nitro-derivatives, action of piperidine with (LE FÈVRE), 3249.
2:2′-*di*sulphide, **-*di*sulphoxide** and **-*di*thiolcarbonate** (BARBER and SMILES), 1146.
1:3-Diphenyl*iso*indole, 1-hydroxy-, hydrobromide (BOYD and LADHAMS), 2091.
Diphenylmethane-2′-carboxylic acid, 4-chloro- (BARNETT and WILTSHIRE), 1823.
9:9-Diphenyl-10-methylene-9:10-dihydroanthracene (BARNETT and COOK), 570.
***NN′*-Diphenyl-*o*-phenylenediamine** (GIBSON and JOHNSON), 1988.
1:3-Diphenylquinoxaline, nitro-derivatives (CHATTAWAY and COULSON), 1084.
***di*-*p*-nitro-** (CHATTAWAY and COULSON), 1363.
Diphenylsilicanediol, complex condensation products of (KIPPING and MURRAY), 1427.
Diphenylsulphone, parachor for (FREIMAN and SUGDEN), 268.
Diphenylsulphone-2′-carboxylic acid, chloro-2:5-*di*hydroxy- and 2:5-*di*-hydroxy-, and its derivatives (PRICE and SMILES), 3156.
***s*-Diphenylthioleth**ane, and its disulphoxides (BELL and BENNETT), 3190.
Dipinacolincarbohydrazone (MUNRO and WILSON), 1259.
Dipinacolinhydrazidicarbohydrazone (MUNRO and WILSON), 1259.
Dipinene, oxidation of (BRIGGS and SHORT), 3118.
4:4′-Dipiperidino-5:5′-*di*nitro-3:3′-dimethyldiphenyl (LE FÈVRE and TURNER), 967.
Di*iso*propenyl, catalytic hydrogenation of (LEBEDEV and YAKUBCHIK), 2191.
Dipropionyltartaric acid, methyl ester (FINDLAY and CAMPBELL), 1773.
3:4′-Diquinolyl, and its picrate and ethiodide (MILLS and ORDISH), 85.
Diquinolyl-2-carboxylic acids (MILLS and ORDISH), 85.
Disalicylyl selenide (MORGAN and BURSTALL), 3270.
Dispersion, rotatory (WOOD and NICHOLAS), 1696.
of optically active co-ordination compounds (WOOD and NICHOLAS), 1727.
anomalous, in relation to the Drude equation (WOOD and NICHOLAS), 1671.
of configuratively related compounds (WOOD and NICHOLAS), 1712.
Distyryl ketone, 5:5′-*di*bromo-2:2′-*di*-hydroxy-, and 4:4′-*di*hydroxy- (MCGOOKIN and SINCLAIR), 1173.
mono- and *di*-chloro- (HEILBRON and HILL), 2866.
Distyryl ketones, action of ethyl acetoacetate with (HEILBRON and HILL), 2863.
2:3-Distyryl-6-methylquinoxaline, and its nitro-derivatives (BENNETT and WILLIS), 1971.
2:3-Distyrylquinoxalines, and *di*chloro-*di*iodo- and *di*- and *tetra*-nitro- (BENNETT and WILLIS), 1968, 1970.
Disulphoxides, stereoisomerism of (BELL and BENNETT), 86, 3189.
Ditetramethylammonium molybdenyl *penta*chloride (JAMES and WARDLAW), 2737.
Dithian *mono*xide, and its derivatives (BELL and BENNETT), 90.

Dithian *di*oxides, derivatives of (BELL and BENNETT), 88.
α- and β-Dithianbis-*p*-toluenesulphonylimines (BELL and BENNETT), 92.
1:3-Dithian-2-carboxylic acid, and its *di*iodo-derivative (CHIVERS and SMILES), 701.
1:3-Dithiolan-2-carboxylic acid, and its dihalides (CHIVERS and SMILES), 700.
Dithymylacetamide (BELL and HENRY), 2224.
Dithymylacetonitrile, and its acetyl derivative (BELL and HENRY), 2224.
Ditolyl. See Dimethyldiphenyl.
Di-*m*-tolyl *di*sulphide, *di*-4-iodo- (BARBER and SMILES), 1144.
Di-*p*-tolyl *di*selenide, *di*-2-nitro- (CHALLENGER and PETERS), 1369.
Di-*p*-tolylbromostibine (GODDARD and YARSLEY), 721.
Di-*p*-tolylchlorostibine (GODDARD and YARSLEY), 720.
Di-*p*-tolyliodostibine (GODDARD and YARSLEY), 721.
γ-Di-*o*-tolyloxy*iso*propyl phosphate, sodium salt (BOYD and LADHAMS), 220.
αγ-Di-*p*-tolyloxy*iso*propyl phosphate (BOYD and LADHAMS), 218.
1-αγ-Ditolyl*iso*propylpyridinium nitrates (BOYD and LADHAMS), 220.
Di-*p*-tolylsilicanediol, complex condensation products of (KIPPING and MURRAY), 1427.
Di-*p*-tolylstibine *tri*chloride (GODDARD and YARSLEY), 721.
Di-*p*-tolylstibinic acid (GODDARD and YARSLEY), 721.
s-Di-*p*-tolylthiolethane, and its disulphoxides (BELL and BENNETT), 3190.
Ditrimethylammonium molybdenyl *penta*chloride (JAMES and WARDLAW), 2737.
Divinyl, catalytic hydrogenation of (LEBEDEV and YAKUBCHIK), 2198.
Dodecoic acid, 11-bromo-, methyl ester, and 11-hydroxy-, and its magnesium salt (BHATTACHARYA, SALETORE, and SIMONSEN), 2679.
Drying, intensive, experiments on (PURCELL), 1207.
influence of, on inner equilibria (SMITS), 2399.

E.

Elaidic acid, methyl ester, oxidation of, by hydrogen peroxide in presence of acetic acid (HILDITCH and LEA), 1576.
Electrical conductivity of uni-univalent salts in benzonitrile (MARTIN), 3270.
Electrodes, platino–platinicyanide, potential of (TERREY), 202.
Electrolysis of solutions with an antimony cathode (GRANT), 1987.
Electrolytes, strong, dissociation of (MARTIN), 3270.
Ephedra, alkaloids from species of (SMITH), 51.
Equilibrium, effect of structure on mobility and (BAKER), 1979.
in solutions (WYNNE-JONES), 1230; (SOPER), 1233.
inner, effect of intensive drying on (SMITS), 2399.
Esters, autocatalysis of hydrolysis of (DAWSON and LOWSON), 3218.
alkaline hydrolysis of, in aqueous alcoholic solutions (GYNGELL), 1784.
Esterification, inhibition of, by alkaline substances (BAILEY), 3256.
by pyridine (BAILEY), 1204.
Ethanetetracarboxylic acid, ethyl ester, sodium derivative, action of dibromotetracarboxylic esters on (LENNON and PERKIN), 1513.
Ethenyl-*o*-aminophenol, 5-amino- and 5-nitro- (NEWBERY and PHILLIPS), 121.
Ethers, influence of structure on solubility of (BENNETT and PHILIP), 1930, 1937.
olefinic, action of bromine water on (READ and REID), 1487.
ω-Ethoxy-9-benzylanthracene, 4-chloro- (COOK), 2810.
3-Ethoxydiphenyl, 5-bromo- and 5-chloro- (HINKEL and HEY), 1203.
2-Ethoxymandelic acid, 5-nitro- (CHATTAWAY and MORRIS), 3244.
2-Ethoxy-4-methylmandelic acid, 5-nitro- (CHATTAWAY and CALVET), 1093.
Ethoxynickelosalicylic acid, methyl ester (DOAK and PACKER), 2769.
ω-Ethoxy-10-phenyl-9-benzylanthracene, 1:5-*di*chloro- (COOK), 2805.
γ-Ethoxy-α-phenylpropane, γ-imino-, hydrochloride (CLEMO and WATSON), 728.
γ-Ethoxypropane, α-chloro-γ-imino-, hydrochloride (CLEMO and WATSON), 729.
3-Ethoxy-*p*-toluic acid, 6-nitro- (CHATTAWAY and CALVET), 1093.
2-Ethoxy-*p*-tolylglyoxylic acid, 5-nitro-, and its phenylhydrazone (CHATTAWAY and CALVET), 1093.
Ethyl borate, preparation and constants of (ETRIDGE and SUGDEN), 992.

3-Ethylamino-3-hydroxy-1:4-benz*iso*oxazine-6-arsinic acid, 8-β-hydroxy- (NEWBERY, PHILLIPS, and STICKINGS), 3062.
9-Ethylanthracene, 2-chloro- and 2-chloro-10-bromo- (BARNETT and WILTSHIRE), 1824.
Ethylarsinic acid, β-chloro-, and β-hydroxy-, and its calcium salt (GOUGH and KING), 2432.
3-Ethyl-5:6-benz-4-carboline (KERMACK and SLATER), 42.
methosulphate (KERMACK and SLATER), 797.
Ethylbenzene, *di*nitro-derivatives, 2-nitro-4-amino-, acetyl derivative, and 2:3-*di*nitro-4-amino-, and its acetyl derivative (BRADY, DAY, and ALLAM), 980.
Ethylbenzenes, halogenated (ASHWORTH and BURCKHARDT), 1791.
2-Ethylbenziminazolearsinic acid, and 2-α-hydroxy- (PHILLIPS), 3137.
2-Ethyl-1:4-benz*iso*oxazine-6-arsinic acid, 3-amino-3-hydroxy-, acetyl derivative, and 3-hydroxy- (NEWBERY, PHILLIPS, and STICKINGS), 3063.
1-Ethylbenzthiazole, and its picrate (CLARK), 2319.
β-Ethylbutyrolactone, and its silver salt (SIRCAR), 901.
Ethylcarbonatoalizarins, and their methyl ethers (PERKIN and STOREY), 240.
Ethyldiethylamine, β-chloro-, and its salts (GOUGH and KING), 2436.
Ethylenediamine, equilibria of phenols with (PUSHIN and SLADOVIĆ), 837.
Ethylenic compounds, addition of bromine to, in non-hydroxylic solvents (WILLIAMS and JAMES), 343.
Ethylenethiocarbamide, complex metallic salts with (MORGAN and BURSTALL), 143.
Ethyl ether, action of disilicon hexachloride on (KIPPING and THOMPSON), 1989.
α-Ethylideneglutaric acid, α'-amino-, ethyl ester (CLEMO and WELCH), 2627.
Ethylnitrolic acid, β-hydroxy- (EARL, ELLSWORTH, JONES, and KENNER), 2701.
Ethyl-*n*-octylsulphone (FENTON and INGOLD), 3129.
Ethylpseudaconine (SHARP), 3103.
***m*-Ethylthiolbenzoic acid** (HOLLOWAY, KENYON, and PHILLIPS), 3003.
β-Ethylvalerolactone, and its silver salt (SIRCAR), 902.
Explosions, striated photographic records of waves of (CAMPBELL and FINCH), 2094.
in closed cylinders (KIRKBY and WHEELER), 3203; (ELLIS and WHEELER), 3215.

F.

Ferric oxide. See under Iron.
Ferrous salts. See under Iron.
Fish, elasmobranch, constituents of oils from (HEILBRON and OWENS), 942.
Flames, moving, study of (PAYMAN), 1738; (ELLIS and WHEELER), 3215.
photographic examination of (WHITE), 1159.
***iso*Flavone group**, syntheses in (BAKER and ROBINSON), 3115.
Flax, pectin and hemicelluloses of (HENDERSON), 2117.
Fluorenone, 2:4:7-*tri*nitro- (BELL), 1990.
Fluorine, action of, on aqueous solutions of chromium and manganese salts (FICHTER and BRUNNER), 1862.
Formic acid, *o*-phenylenediamine salt (PHILLIPS), 2396.
Fuel, liquid, detonation of (MARDLES), 872.
Fungi, mould, degradation of fatty acids by (WALKER and COPPOCK), 803.

G.

Galactose, mutarotation of (SMITH and LOWRY), 666.
Gallacetophenone, diacetyl and ditoluene-*p*-sulphonyl derivatives, and their methyl ethers (PERKIN and STOREY), 242.
Gas circulation apparatus (BARR), 3293.
Gattermann reaction, by-products of (BELL and HENRY), 2215.
Gels, formation of (KNIGHT and STAMBERGER), 2791.
Gelatin, adsorption of hydrogen ions by, in relation to its swelling and electrical charge (GHOSH), 711.
Genistein, synthesis of (BAKER and ROBINSON), 3115.
Glass, adsorption of vapours on (SMITS), 2952.
influence of, on vapour pressure (RINSE), 1442.
boric oxide, density of (COUSEN and TURNER), 2654.
Gluconic acid, thallium salts (MENZIES and KIESER), 189.

Glucosides (HICKINBOTTOM), 3140.
See also Iridin.
3-β-Glucosidylpelargonidin chloride, synthesis of, and its identity with callistephin chloride (ROBERTSON and ROBINSON), 1460.
picrate (ROBERTSON and ROBINSON), 1468.
***d*-Glutamic acid**, action on aniline on (GRAY), 1264.
Glutaric acid, electrometric titration of (GANE and INGOLD), 1598.
l-menthyl hydrogen ester (RULE, HAY, and PAUL), 1357.
Glutaric acids, β-substituted, electrometric titration of (GANE and INGOLD), 2267.
Glycine, action of nitrous acid on (TAYLOR), 1898.
6-Glycineamide-3-chlorophenylarsinic acid, and its salts (BALABAN), 813.
Glyoxal, photochemical decomposition of, and its derivatives (NORRISH and GRIFFITHS), 2829.
Glyoxaline-4(5)-formaldehydes, and their derivatives (HUBBALL and PYMAN), 21.
Glyoxaline-4(5)-methylideneaniline (HUBBALL and PYMAN), 25.
2-[Glyoxalinyl-4(5)]-β-naphthacinchoninic acid (HUBBALL and PYMAN), 26.
Glyoxylic acid, and its ethyl ester, bromo- and chloro-phenylhydrazones (CHATTAWAY and DALDY), 2759.
"**Goulard's extract.**" See Acetic acid, lead *sub*salt.
Guanidine carbonate, hydrolysis (BELL), 2074.

H.

Hæmatoxylin, and its derivatives, synthesis of (PERKIN, RÂY, and ROBINSON), 1504.
Halogens, addition of, to unsaturated acids and esters (HANSON and JAMES), 1955.
activation of, by a nitro-group in the aromatic nucleus (BREWIN and TURNER), 334.
Halogenation by chloroamines (BRADFIELD, ORTON, and ROBERTS), 782.
Hemicellulose of flax plant (HENDERSON), 2117.
1-*n*-Heptylamino-3-methylbenzthiazole, and its derivatives, and 5-bromo- (HUNTER and STYLES), 3027.
***r*-*cyclo*Heptylcyanoacetic acid**, ethyl ester (VOGEL), 2025.
***cyclo*Heptylidenecyanoacetic acid**, ethyl ester (VOGEL), 2024.
***cyclo*Heptylmalonic acid** (VOGEL), 2025.
***n*-Heptyloxyacetic acid**, and its *l*-menthyl ester and chloride (RULE, HAY, and PAUL), 1356.
Heterocyclic compounds, effect of structure and substitution on stability of (SIRCAR), 898.
Hexa-allylamineperoxodihydroxodicobalt salts (BUCKNALL and WARDLAW), 2649.
Hexahydroacridone, and its oxime (PERKIN and PLANT), 2590.
Hexahydrocarbazole, condensation of, with *cyclo*pentanone cyanohydrin (PLANT and RIPPON), 1906.
Hexahydrocarbazole, 6-chloro-10:11-*di*hydroxy-, acetyl derivative, and 6-chloro-11-nitro-10-hydroxy-, benzoyl derivative (PLANT and ROSSER), 2462.
Hexahydrocarbazole-9-carboxylic acid, 6-chloro-10:11-*di*hydroxy-, and 6-chloro-11-nitro-10-hydroxy-, ethyl esters (PLANT and ROSSER), 2464.
1-(9′-Hexahydrocarbazyl)-1-cyano*cyclo*pentane (PLANT and RIPPON), 1909.
1-(9′-Hexahydrocarbazyl)*cyclo*pentane-1-carboxylamide (PLANT and RIPPON), 1909.
Hexahydrocuroumenes (RAO and SIMONSEN), 2504.
2:3:4:5:11:12-Hexahydroheptindole, and its salts and derivatives (PERKIN and PLANT), 2586.
Hexahydro-αβ-naphthacarbazoles, and their derivatives (OAKESHOTT and PLANT), 1844.
2:3:4:5:12:13-Hexahydroquinindenes, stereoisomeric, and their derivatives (PERKIN and PLANT), 639.
Hexahydroxyplatinic acid. See under Platinum.
2′:4′:6′:2″:4″:6″-Hexamethoxytriphenylmethane-4-carboxylic acid (LUND), 1572.
***n*-Hexane**, oxidation of (BRUNNER and RIDEAL), 1162, 2824.
***cyclo*Hexanealdehyde**, condensation of malonic acid and (SIRCAR), 54.
β-*cyclo*Hexane*spiro*butyrolactone, and its silver salt (SIRCAR), 57, 902.
***cyclo*Hexane*spiro*-4-methyl*cyclo*hexane-3:5-dione** (DICKINS, HUGH, and KON), 1636.
β-*cyclo*Hexane*spiro*valerolactone, and its silver salt (SIRCAR), 903.
***cyclo*Hexanone** chloronitrophenylhydrazone (PLANT and ROSSER), 2461.
Δ^α^-Hexenanilide (GOLDBERG and LINSTEAD), 2351.
Δ^1^-*cyclo*Hexenylacetoacetic acid, and its semicarbazone (JUPP, KON, and LOCKTON), 1640.

Δ^1-*cyclo*Hexenylacetone (DICKINS, HUGH, and KON), 1636.
Δ^1-*cyclo*Hexenylacetylmalonic acid, ethyl ester, and its semicarbazone (JUPP, KON, and LOCKTON), 1641.
Δ^1-*cyclo*Hexenyl-α-ethylcyanoacetic acid, ethyl ester (MCRAE and MANSKE), 486.
Δ^1-*cyclo*Hexenylmethyl ethyl ketone (DICKINS, HUGH, and KON), 1634.
Hexoic acid, allyl ester (DEULOFEU) 528.
Hexopentosan (HENDERSON), 2125.
β-*cyclo*Hexylacrylic acid, and its salts and derivatives (SIRCAR), 55.
γ-*n*-Hexylaminopropylarsinic acid, derivatives of (GOUGH and KING), 2442.
γ-*n*-Hexylaminopropyl*di*chloroarsine hydrochloride (GOUGH and KING), 2443.
***r*-*cyclo*Hexylcyanoacetic acid**, ethyl ester (VOGEL), 2023.
β-*cyclo*Hexylglutaric acid, and its salts and derivatives (SIRCAR), 56.
***cyclo*Hexylideneacetone**, and its semicarbazone (DICKINS, HUGH, and KON), 1630.
***cyclo*Hexylidenemethyl ethyl ketone** (DICKINS, HUGH, and KON), 1630.
***cyclo*Hexylmalonic acid**, preparation of (VOGEL), 2023.
***n*-Hexyloxyacetic acid**, and its *l*-menthyl ester and chloride (RULE, HAY, and PAUL), 1356.
***cyclo*Hexylphenylacetonitrile**, 1-cyano- (MCRAE and MANSKE), 490.
Homomesitones, and their semicarbazones (ABBOTT, KON, and SATCHELL), 2514.
Homophthalic acid, action of phosphorus pentachloride on (DAVIES and POOLE), 1616.
separation of, from phthalic acid, and its copper salt (POOLE), 1378.
Homophthalic anhydrides, enolisation of (STEVENS and WILSON), 2827.
Hops, high-boiling constituents of oil of (CHAPMAN), 1303.
Humulene (CHAPMAN), 785.
Hydration of ions (INGHAM), 2381.
Hydrazine hydrate, dissociation constant of (HUGHES), 502.
Hydrazobenzene, 3:5-*di*bromo- (BURNS, MCCOMBIE, and SCARBOROUGH), 2936.
ω-3-Hydrindonylacetophenone, and its derivatives (JACKSON and KENNER), 579.
Hydroaromatic compounds, conversion of, into aromatic compounds (HINKEL and HEY), 1200, 2786.
Hydrocampnospermanol, and its derivatives (JONES and SMITH), 69.
Hydrocarbons, olefinic, action of bromine water on (READ and REID), 1487.
Hydrochloric acid. See under Chlorine.
Hydroferricyanic acid, potassium salt, solubility of, in water (FRIEND and SMIRLES), 2242.
Hydrogen, effect of intensity of light on photochemical combination of bromine and (BRIERS and CHAPMAN), 1802.
photochemical combination of chlorine and, in glass capillary tubes (CHAPMAN and GRIGG), 3233.
inflammation of mixtures of air and (MAXWELL and WHEELER), 15.
Hydrogen sulphide, action of, on hydrated ferric oxide at 100° (PEARSON and ROBINSON), 814.
reaction of nitrous acid with (BAGSTER), 2631.
*penta*sulphide (MILLS and ROBINSON), 2326.
Hydrogenation of extended heterogeneous systems (EVANS and FARMER), 1644.
Hydrohydrastinine phenacyloiodide (STEVENS, CREIGHTON, GORDON, and MACNICOL), 3196.
Hydroxy-acids, esters, metallic derivatives of (DOAK and PACKER), 2763.
Hyponitrites. See under Nitrogen.

I.

2:3-Indeno(1:2)-indole (TITLEY), 2576.
Indium, electrodeposition of, with the dropping mercury cathode (TAKAGI), 301.
detection and determination of, in gallium (TAKAGI), 305.
ψ-*iso*Indole, attempted preparation of (FENTON and INGOLD), 3295.
Indole series, syntheses in (KERMACK and SLATER), 32, 789.
1·2-Indole(2:3)-3:4-dihydronaphthalene (TITLEY), 2577.
Indoxylacetic acid (JACKSON and KENNER), 580.
ψ-Indoxyl*spiro*cyclohexane, derivatives of (BETTS and PLANT), 2070.
Inks, carbon (CHIRNOAGA), 300.
Inulin, structure of (HAWORTH and LEARNER), 619.
molecular complexity of (DREW and HAWORTH), 2690.
Iodination by chloroamines and iodides (BRADFIELD, ORTON, and ROBERTS), 782.
Iodine, hydrogen-ion concentration in aqueous solutions of (DAWSON), 259.

Iodine, equilibria of, in solutions of iodides (COOPER), 2227.
water catenary in reaction of acetone with (DAWSON and KEY), 543.
Ions, hydration of (INGHAM), 1917, 2381.
Ionisation constants, determination of (DAWSON, HALL, and KEY), 2844.
Iridin, constitution of (BAKER), 1022.
Irigenin, constitution of, and its derivatives (BAKER), 1022.
Irigenol, and its derivatives (BAKER), 1030.
Iron, passivity of (HEDGES), 970.
Iron nitride, formation of, in the iron–nitrogen arc (WILLEY), 2840.
sulphides, determination of iron and sulphur in (ROBINSON, SAYCE, and STEVENSON), 813.
Ferric oxide, hydrated, action of hydrogen sulphide on, at 100° (PEARSON and ROBINSON), 814.
Ferrous sulphate, stability of solutions of, and their use in standardising permanganate (FRIEND and PRITCHETT), 3227.
Iron, determination of, in iron sulphides (ROBINSON, SAYCE, and STEVENSON), 813.
Isomerism, dynamic (SMITH and LOWRY), 666; (LOWRY, MACCONKEY, and BURGESS), 1383; (LOWRY, MOUREU, and MACCONKEY), 3167.
Isoprene, hydrogenation of (LEBEDEV and YAKUBCHIK), 827.

K.

3-Keto-3:4-dihydro-5:6-benz-4 carboline (KERMACK and SLATER), 39.
4-Keto-3:4-dihydroquinazoline-2-thioglycollic acid, ethyl ester (STEPHEN and WILSON), 1421.
α-Keto-γγ-dimethyl*iso*heptoic acid, δ-amino-, lactam (INGOLD and SHOPPEE), 399.
11-Keto-5:7:8:9:10:11-hexahydroheptaquinoline (PERKIN and PLANT), 2588.
1-Ketohydrindene-3-acetic acid, and its derivatives (JACKSON and KENNER), 577.
1-Ketoindene, 3-chloro-2-bromo-, and its oxime (HANSON and JAMES), 2983.
Ketols, aromatic reduction of nitro-compounds by (NISBET), 3121.
Keto-lactone, $C_{10}H_{16}O_3$, from oxidation of α-phellandrene (HENRY and PAGET), 77.
4-Keto-1-methoxy-3-(3′-nitrophenyl)-3:4-dihydrophthalazine (ROWE, HIMMAT, and LEVIN), 2562.
4-Keto-1-methoxy-3-(4′-nitrophenyl)-3:4-dihydrophthalazine (ROWE and LEVIN), 2554.
3-Keto-1-methyl-3:4-dihydro-5:6-benz-4-carboline (KERMACK and SLATER), 43.
1-Keto-2-methyltetrahydronaphthalene (TITLEY), 2578.
1-Keto-2-methyl-1:2:3:4-tetrahydronaphthalene-2-carboxylic acid, ethyl ester (TITLEY), 2577.
Ketone, $C_{13}H_{20}O$, and its semicarbazone, from piperitone and ethyl acetoacetate (JUPP, KON, and LOCKTON), 1644.
Ketones, condensation of, with ethyl acetoacetate (JUPP, KON, and LOCKTON), 1638.
of the morphine group, condensation of aldehydes with (GULLAND), 702.
γ-Ketonic acids, synthesis of (BARDHAN), 2591, 2604.
β-Ketonic compounds, conductivities of potassium and sodium derivatives of, in alcoholic solution (WHITE), 1413.
β-Ketonic esters, condensation of *o*-hydroxystyryl ketones with (HILL), 256.
3-Keto-2-*p*-nitrophenyl-2:3-dihydrothionaphthen 1:1-dioxide (PRICE and SMILES), 2862.
3-Ketophenheptamethylene-2-carboxylic acid, ethyl ester, phenylhydrazone (TITLEY), 2579.
(γ-Keto-α-phenyl-ε-2-chlorophenyl-Δ$^{\delta}$-pentenyl)acetoacetic acid, ethyl ester (HEILBRON and HILL), 2868.
5-Keto-2-phenyl-4-(2′:5′-dimethoxybenzylidene)-4:5-dihydro-oxazole (GULLAND and VIRDEN), 1481.
5-Keto-2-phenyl-4-(6′-methoxy-3′-ethylbenzylidene)-4:5-dihydro-oxazole (GULLAND and VIRDEN), 930.
α-Keto-ββγγ-tetramethylvaleric acid, δ-amino-, lactam (INGOLD and SHOPPEE), 395.
Kolbe's reaction, mechanism of (WALKER), 2040.

L.

Lauric acid, potassium salt, hydrolysis in solutions of, as measured by extraction with benzene (MCBAIN and EATON), 2166.
Laurotetanine, constitution of (BARGER and SILBERSCHMIDT), 2919.
Lead iodide, precipitation of, in agar (HEDGES and HENLEY), 2718.
oxyhyponitrite (NEOGI and NANDI), 1454.

Lectures delivered before the Chemical Society (FOWLER), 764; (WALKER), 1380.
Liesegang rings, formation of, as a periodic coagulation (HEDGES and HENLEY), 2714.
Limonene, oxidation of (HENRY and PAGET), 75.
Liquids, constitution of (BAKER), 1051.
determination of density of (GRINDLEY), 3297.
organic mixed, cryoscopy of compound formation in (MADGIN, PEEL, and BRISCOE), 707.
Lithium chloride, densities and viscosities of hydrochloric acid solutions of (INGHAM), 2381.
hyponitrite (NEOGI and NANDI), 1451.
sulphites, and their derivatives (FRIEND and POUNDER), 2245.
Lupanine, and its derivatives (CLEMO and LEITCH), 1815.
*iso***Lupanine**, and its methiodide (CLEMO and LEITCH), 1819.
Luparenol (CHAPMAN), 1304.
Luparol (CHAPMAN), 1305.
Luparone (CHAPMAN), 1304.
Lupin alkaloids. See under Alkaloids.
Lyxose, structure and derivatives of (HIRST and SMITH), 3147.
new form of (HAWORTH and HIRST), 1221.

M.

Magnesium, interaction of alkyl and aryl halides with (RUDD and TURNER), 686.
Magnesium alloys with mercury, reduction of nitrates, nitric acid, and nitrites by (NEOGI and NANDI), 1449.
Magnesium hydroxide, diffusion of, in gelatin (HEDGES and HENLEY), 2719.
Magnesium organic compounds:—
Magnesium phenyl bromide, action of, on methyl *o*-cyanobenzoate (BOYD and LADHAMS), 2089.
Malic acid, optical activity of, in presence of sodium molybdate (PATTERSON and BUCHANAN), 3006.
Malonanilic acid, 2-amino- (PHILLIPS), 2398.
Malonic acid, electrometric titration of (GANE and INGOLD), 1598.
condensation of *cyclo*hexanealdehyde and (SIRCAR), 54.
esters, synthesis of, by means of toluenesulphonic esters (PEACOCK and THA), 2303.
diethyl ester, aluminium derivative (BURROWS and WARK), 228.
Malonic acid, diethyl ester, sodium derivative, action of dibromotetracarboxylic esters on (LENNON and PERKIN), 1513.
Malonic acids, substituted, synthesis of (VOGEL), 2010.
Malvidin chloride, synthesis of, and its benzoyl derivative (BRADLEY and ROBINSON), 1541.
l-**Mandelic acid**, butyl esters, rotatory dispersion of (WOOD, CHRISMAN, and NICHOLAS), 2180.
Manganese salts, density and electrostriction of dilute solutions of (CAMPBELL), 653.
action of fluorine on aqueous solutions of (FICHTER and BRUNNER), 1862.
Manganese sulphate, equilibrium of, with sodium sulphate and water (CAVEN and JOHNSTON), 2506.
Permanganates, standardisation of, with ferrous sulphate solution (FRIEND and PRITCHETT), 3227.
Memorial Lecture, Arrhenius (WALKER), 1380.
dl-Δ^3-**Menthene**, action of bromine water on (READ and REID), 1492.
Mercury alloys with magnesium, reduction of nitrates, nitric acid, and nitrites by (NEOGI and NANDI), 1449.
with platinum, adsorption of gases on (SMITH), 2045.
Mesityl oxide, catalysis in iodination of (DAWSON and KEY), 2154.
Metals, passivity of (HEDGES), 969.
Metallic salts, equilibria between alcohols and (LLOYD, BROWN, BONNELL, and JONES), 658.
See also Salts.
Methane, explosions of mixtures of air and, in long cylinders (KIRKBY and WHEELER), 3203.
Methosulphates, constitution of (KERMACK and SLATER), 789.
4-Methoxyazobenzenes, bromo-, chloro-, and 3:4′-*di*nitro- (BURNS, MCCOMBIE, and SCARBOROUGH), 2934.
Methoxybenzaldehydes, nitrophenylhydrazones of (HODGSON and HANDLEY), 1885.
o-*p*-**Methoxybenzaldoxime**, nitration of (BRADY and MILLER), 341.
5-Methoxybenzene 2:1-diazosulphide (HODGSON and HANDLEY), 626.
3-Methoxybenzoic acid, 2-iodo-, and its methyl ester (KENNER and TURNER), 2341.
1-Methoxy-1:2:3-benztriazole (BRADY and REYNOLDS), 198.
ω-**Methoxy-9-benzylanthracenes, chloro-** (COOK), 2808.

10-**Methoxy-9-benzylidene-9:10-dihydroanthracene**, 1-chloro- (COOK), 2808.
2-**Methoxy-1-αββδ-*tetra*chloroethylbenzene**, 5-nitro- (CHATTAWAY and CALVET), 2917.
3-**Methoxycinnamic acid**, bromo-derivatives (H. and W. DAVIES), 603.
Methoxycuprisalicylic acid, methyl ester (DOAK and PACKER), 2767.
3-**Methoxydimethylaniline**, 5-chloro-, and 5-chloro-4-nitroso- (HODGSON and WIGNALL), 331.
4′-**Methoxy-6:8-dimethylflavylium chloride**, 5-hydroxy- (ROBERTSON, ROBINSON, and STRUTHERS), 1458.
2′- and 4′-**Methoxydiphenylamines**, 2-amino- and 2-nitro- (MCCOMBIE, SCARBOROUGH, and WATERS), 356.
2′-**Methoxydiphenyl-2-carboxylic acid**, menthyl ester (BRETSCHER, RULE, and SPENCE), 1502.
3-**Methoxy-4-ethoxybenzaldehyde**, 6-nitro- (BARGER and SILBERSCHMIDT), 2927.
6-**Methoxy-3-ethylbenzaldehyde**, and its semicarbazone (GULLAND and VIRDEN), 929.
2-(6′-**Methoxy-3′-ethylbenzyl)quinoxaline**, 3-hydroxy- (GULLAND and VIRDEN), 931.
6-**Methoxy-3-ethylphenylacetic acid**, and its sodium salt (GULLAND and VIRDEN), 931.
trans-α-(6′-**Methoxy-3′-ethylphenyl)-2-amino-3:4-dimethoxycinnamic acid** (GULLAND and VIRDEN), 932.
trans-α-(6′-**Methoxy-3′-ethylphenyl)-2-nitro-3:4-dimethoxycinnamic acid**, and its ammonium salt (GULLAND and VIRDEN), 931.
6-**Methoxy-3-ethylphenylpyruvic acid**, and its sodium salt (GULLAND and VIRDEN), 930.
α-3-**Methoxy-4-hydroxybenzaldoxime**, nitration of (BRADY and MILLER), 342.
1-**Methoxy-6-methyl-1:2:3-benztriazole** (BRADY and REYNOLDS), 201.
4-**Methoxy-3-methyltetraphenylmethane**, and 3-bromo- (BOYD and HARDY), 637.
2-**Methoxynaphthalene**, 3-bromo- and 3-iodo- (CLEMO and SPENCE), 2818.
Methoxynaphthoic acids, and their menthyl esters (BRETSCHER, RULE, and SPENCE), 1499.
2-**Methoxy-3-naphthylamine**, and its acetyl derivative (CLEMO and SPENCE), 2818.
Methoxynickelosalicylic acid, methyl ester (DOAK and PACKER), 2768.
3-**Methoxy-5-*cyclo*pentanespirocyclopenten-1:4-dione** (GOSS), 1308.
2-**Methoxyphenazine**, and its chloroplatinate (MCCOMBIE, SCARBOROUGH, and WATERS), 357.
β-*p*-**Methoxyphenylglutaric acid**, and its derivatives (JACKSON and KENNER), 1660.
5-**Methoxyphenylmethylsulphones**, nitro- (HODGSON and HANDLEY), 627.
p-**Methoxyphenylpropane-ααγ-tricarboxylic acid**, ethyl ester (JACKSON and KENNER), 1660.
β-*p*-**Methoxyphenyl*iso*propylamines**, β-hydroxy-, and their derivatives (READ and REID), 1489.
2-**Methoxy-α-phenylstyryl benzyl ketone** (DICKINSON, HEILBRON, and O'BRIEN), 2080.
4-**Methoxy*iso*phthalaldehydic acid**, and its 2:4-dichlorophenylhydrazone (CHATTAWAY and CALVET), 2916.
4-**Methoxy*iso*phthalic acid** (CHATTAWAY and CALVET), 2916.
2-**Methoxystyrene**, αββ-*tri*chloro-5-nitro- (CHATTAWAY and CALVET), 2917.
2-*p*-**Methoxystyryl-3:6-dimethylquinoxaline** (BENNETT and WILLIS), 1971.
Methoxystyryl ethyl ketones, hydroxy- (MCGOOKIN and SINCLAIR), 1174.
2-**Methoxystyryl-3-methylquinoxalines** (BENNETT and WILLIS), 1969.
Methoxystyryl propyl ketones, hydroxy- (MCGOOKIN and SINCLAIR), 1174.
1(or 5)-**Methoxy-2:2:3:3-tetramethyl-*cyclo*pentan-5(or 1)-one**, and its oxime (SHOPPEE), 1670.
5-**Methoxy-2:2:3:3-tetramethyl-*cyclo*pentanone** (INGOLD and SHOPPEE), 402.
5-**Methoxy-2:2:3:3-tetramethyl-*cyclo*pentanone**, *di*bromo- (SHOPPEE), 2363.
5-**Methoxythioanisoles**, chloro- (HODGSON and HANDLEY), 627.
Methyl borate, preparation and constants of (ETRIDGE and SUGDEN), 991.
sec.-**butyl ether** (BENNETT and PHILIP), 1931.
ethers, aromatic, sulphur derivatives of (HODGSON and HANDLEY), 625.
iodide, action of cuprous cyanide on (HARTLEY), 780.
Methylamine, action of nitrous acid on (TAYLOR), 1100.
1-**Methylamino-3-methylbenzthiazole**, and its acetyl derivative (HUNTER and STYLES), 3025.
9-**Methylanthracene**, 2-chloro- (BARNETT and WILTSHIRE), 1824.

Methylarabinoside, trithallium compound of (MENZIES and KIESER), 188.
Methylation, mechanism of (INGOLD and VASS), 3125.
4-Methylazobenzenes, bromo- and nitro- (BURNS, MCCOMBIE, and SCARBOROUGH), 2931.
Methylbenzaldoximes, nitration of (BRADY and MILLER), 339.
3-Methyl-5:6-benz-4-carboline, and its salts (KERMACK and SLATER), 42.
Methylbenzcarbolines, and their derivatives (KERMACK and SLATER), 795.
2-Methylbenziminazoles, formation of, and amino- and nitro- (PHILLIPS), 172.
Methylbenziminazolearsinic acids (PHILLIPS), 3136.
4-Methylbenzophenone, amino-, bromo- and nitro-derivatives of, and their derivatives (BLAKEY and SCARBOROUGH), 2492.
Methyl-1 4-benz*iso*oxazinearsinic acids, aminohydroxy-, acetyl derivative, and hydroxy- (NEWBERY, PHILLIPS, and STICKINGS), 3061.
1-Methylbenzselenazole, and its salts (CLARK), 2316.
1-Methylbenzthiazole, salts of (CLARK), 2315.
3-Methylbenzthiazole, 1-amino- and its acetyl derivative, and 5-bromo-1-amino-, and their bromides (HUNTER and STYLES), 3022.
1-Methyl-1:2:3-benztriazole 1-oxide (BRADY and REYNOLDS), 198.
6-Methyl-1 2:3-benztriazole, 1-hydroxy-, and its derivatives (BRADY and REYNOLDS), 200.
4-Methylbenzyl ethyl ethers, nitro- (INGOLD and ROTHSTEIN), 1279.
***p*-Methylbenzylbenzoylacetic acid**, ethyl ester (BURTON and INGOLD), 920.
Methyl benzyl ketone, hydroxy-, *p*-nitrobenzoyl derivative (BRADLEY and SCHWARZENBACH), 2906.
7-Methyl-2:4-bis*tri*chloromethyl-1:3-benzdioxin, 6-nitro- (CHATTAWAY and CALVET), 1092.
β-Methylbutane, γ-amino-β-hydroxy-, and its derivatives (READ and REID), 1491.
β-Methylbutyrolactone, and its silver salt (SIRCAR), 901.
4-Methylcarbonatoacetophenone, ω-hydroxy- (ROBERTSON and ROBINSON), 1465.
Methyl-β-chloroethyldiethylammonium chloride and iodide (GOUGH and KING), 2437.
Methylchloromethylene-1:3-benzdioxin, 6-*mono*- and 6:8-*di*-nitro- (CHATTAWAY and MORRIS), 3243.
α-Methylcinnamyl alcohol, and its derivatives (BURTON and INGOLD), 915; (BURTON), 1656.
8-Methyl-2:2′-diallylthiocarbocyanine bromide (HAMER), 3162.
Methyldiethylamine-ββ′-diarsinic acid, (GOUGH and KING), 2435.
6(or 6′)-Methyl-1:1′-diethyl-ψ-cyanine iodide (HAMER), 212.
8-Methyl-2:2′-diethylthiocarbocyanine iodide (HAMER), 3162.
7-Methyl-3:4-dihydrocoumarin-4-acetic acid (SESHADRI), 170.
7-Methyl-3:4-dihydrocoumarin-4-cyanoacetic acid, and its amide (SESHADRI), 170.
1-Methyldihydro*iso*indole, 2-*p*-toluenesulphonyl derivative (FENTON and INGOLD), 3296.
2′-Methyldiphenylamine, 2-amino-, and its tin salt, and 2-nitro- (MCCOMBIE, SCARBOROUGH, and WATERS), 355.
α-3:4-Methylenedioxybenzaldoxime, nitration of (BRADY and MILLER), 342.
4:5-Methylenedioxyhomophthalic anhydride (STEVENS and WILSON), 2827.
2-Methylenedioxystyryl-3-methylquinoxaline (BENNETT and WILLIS), 1968.
β-Methyl-β-ethylbutyrolactone, and its silver salt (SIRCAR), 901.
1(or 1′)-Methyl-1′(or 1)-ethyl-ψ-cyanine iodide (HAMER), 210.
Methylethylthio-ψ-cyanine iodides (HAMER), 214.
β-Methyl-β-ethylvalerolactone, and its silver salt (SIRCAR), 903.
2-Methylglucose phenylhydrazone (HICKINBOTTOM), 3146.
1-Methylglyoxaline-4- and -5-carboxylic acids, methyl esters (HUBBALL and PYMAN), 31.
1-Methylglyoxaline-5-formaldehyde nitrate and picrate (HUBBALL and PYMAN), 27.
4(5)-Methylglyoxaline-5(4)-formaldehyde picrate (HUBBALL and PYMAN), 28.
***N*-Methylhemipinimide**, preparation of (BRADY, BAKER, GOLDSTEIN, and HARRIS), 536.
ε-Methylhepten-γ-ones, and their semicarbazones (ABBOTT, KON, and SATCHELL), 2522.
3-Methylhexahydrocarbazoles, and their derivatives (PLANT and ROSSER), 2460.
4-Methyl*cyclo*hexanone, phenylhydrazones of (PLANT and ROSSER), 2457.

2-Methyl-1-hydrindone-2-carboxylic acid, ethyl ester (TITLEY), 2577.
1-Methyl-5-hydroxymethylglyoxaline picrate (HUBBALL and PYMAN), 28.
β-*p*-Methyl-*o*-hydroxyphenylglutaric acid (SESHADRI), 170.
Methyl-1:4 *di*hydroxythioxanthone *di*oxide (PRICE and SMILES), 3158.
***O*-Methylindoxylacetic acid** (JACKSON and KENNER), 580.
Methyl-ψ indoxyl*spirocyclo*hexanes, and their acetyl derivatives, and nitro- (BETTS and PLANT), 2072.
3-Methyl-ψ-indoxyl*spirocyclo*pentane, and its acetyl derivative (PLANT and ROSSER), 2458.
Methyl-lupanines, and their derivatives (CLEMO and LEITCH), 1816.
Methylmesityl oxide, and its semicarbazone (BARDHAN), 2614.
2-Methyl-1-methylenebenzselenazoline (CLARK), 2317.
2-Methyl-1-methylenebenzthiazoline, and its benzoyl derivative (CLARK), 2315.
α-*O*-Methyl-3:4-methylenedioxybenzaldoxime, nitration of (BRADY and MILLER), 342.
***O*-Methyl-3:5-*di*nitro-4-methoxybenzaldoxime** (BRADY and MILLER), 341.
Methylopianic oximes (BRADY, BAKER, GOLDSTEIN, and HARRIS), 536.
Methyl*cyclo*pentadiene, derivatives of (GOSS and INGOLD), 1268.
α-Methyl*cyclo*pentane-1:1-diacetic acid, and its derivatives, and **αα'-*di*cyano-**, ***N*-methyl-ω-imide**, and **α-hydroxy-**, lactone, and its derivatives (BARDHAN), 2598.
α'-Methyl*cyclo*pentane-1:1-diacetic acid, **α-bromo-**, ethyl ester, and **α-bromo-αα'-*di*cyano-**, methylimide (BARDHAN), 2599.
1-Methyl*dicyclo*pentane-2:4:5-tricarboxylic acid, **3-amino-**, ethyl esters (GOSS and INGOLD), 1277.
1-Methyl*dicyclo*pentan-3-one-5-carboxylic acid (GOSS and INGOLD), 1275.
5-Methyl*dicyclo*pentan-3-one-1-carboxylic acid, and its oxime (GOSS and INGOLD), 1273.
1-Methyl*dicyclo*pentene-2:4:5-tricarboxylic acid, **3-amino-**, esters (GOSS and INGOLD), 1274.
Methylpentenoic acids, preparation and derivatives of (GOLDBERG and LINSTEAD), 2353.
5-Methyl*dicyclo*penten-3-oldicarboxylic acid, methyl hydrogen ester (GOSS and INGOLD), 1273.
5-Methyl*dicyclo*penten-3-ol-1:2:4-tricarboxylic acid, esters (GOSS and INGOLD), 1272.
α-Methyl-Δ^1-*cyclo*pentenylacetone, and its semicarbazone (BARDHAN), 2604.
α-Methyl*cyclo*pentylideneacetic acid, and its derivatives (BARDHAN), 2603.
α-Methyl*cyclo*pentylideneacetone, and its semicarbazone (BARDHAN), 2603.
1-Methylphenazine, preparation of, and its chloroplatinate (MCCOMBIE, SCARBOROUGH, and WATERS), 355.
Methylphenoxtellurine, chloro-, and its salts and phenoxtellurine compound (DREW), 510.
Methylphthalide, 5-hydroxy*tri*chloro- (CHATTAWAY and CALVET), 1092.
Methylphthaloximes, hydrolysis of (BRADY, BAKER, GOLDSTEIN, and HARRIS), 539.
α-Methyl-α-Δ^1-pulegenylacetone, and its semicarbazone (JUPP, KON, and LOCKTON), 1643.
3-Methyl-5-pyrazolone-1-carboxy-α-carbethoxy*iso*propylidenehydrazide (MUNRO and WILSON), 1260.
6-Methylquinoline, 2-chloro-, and 2-iodo-, methiodide (HAMER), 210.
2-Methylquinoxaline, 2-ω-*tri*bromo- (BENNETT and WILLIS), 1974.
2-Methylquinoxaline-3-pyruvic acid, ethyl ester, and its *p*-nitrophenylhydrazone (BENNETT and WILLIS), 1974
4-Methylstyryl nonyl ketone, and its dimeride (HEILBRON and IRVING), 2325.
3-Methyltetrahydrocarbazole, and nitro-, and their acetyl and benzoyl derivatives (PLANT and ROSSER), 2457.
3-Methyltetrahydrocarbazole-9-carboxylic acid, and 10:11-*di*hydroxy- and nitro-, ethyl esters (PLANT and ROSSER), 2459.
3-Methyltetrahydropentindole, and its salts (PLANT and RIPPON), 1911.
Methylthiolbenzaldehydes, nitrophenylhydrazones of (HODGSON and HANDLEY), 1885.
2-Methylthiolhydrazine (HODGSON and HANDLEY), 1884.
Methylthiolphenylhydrazines (HODGSON and HANDLEY), 1884.
β-Methyltrimethylenediamine, complex platinum salts of (MANN), 1261.
β-Methylvalerolactone, and its silver salt (SIRCAR), 902.
Migrations, transannular anionotropic (OOK), 2798.
Molecular dissymetry (MILLS and ELLIOTT), 1291.

Molybdenum, surface oxidation of (BANNISTER), 3163.
Molybdenum organic compounds:—
Molybdenum oxalates, complex (SPITTLE and WARDLAW), 2742.
thiocyanates, complex (JAMES and WARDLAW), 2726.
Molybdenyl acetylacetone (MORGAN and CASTELL), 3255.
Molybdyl bis-β-diketones (MORGAN and CASTELL), 3252.
Monosaccharides, structure of (HIRST and SMITH), 3147.
1-Morphothebaine dimethyl ethers, and their derivatives (GULLAND and HAWORTH), 2088.
Moulds, degradation of fatty acids by (COPPOCK, SUBRAMANIAM, and WALKER), 1422.
Muconic acid, ethyl ester, hydrogenation of (EVANS and FARMER), 1646.
Myoporum laetum ("ngaio"), constituents of (MCDOWALL), 1324.

N.

α-Naphthaldehyde *p*-nitrophenylhydrazone (SHOESMITH and GUTHRIE), 2332.
Naphthalene, 1:8-*di*thiol-, and its nickel derivative (PRICE and SMILES), 2373.
Naphthalene-2-sulphinic acid, 1-iodo- (BARBER and SMILES), 1145.
Naphthalenesulphonic acid, bornyl and menthyl esters, decomposition and hydrolysis of (PATTERSON and MCALPINE), 2464.
Naphthalene-2-sulphonic acid, 1-iodo-, and its derivatives (BARBER and SMILES), 1144.
α-Naphthalenesulphonylalanines, *dl*- and *d*-, ethyl esters (COLLES and GIBSON), 108.
1:2-Naphthaquinone 2′-carboxyphenyl sulphoxide, and its derivatives (PRICE and SMILES), 3159.
3:4-Naphthathioxanthone-1:2-quinone (PRICE and SMILES), 3159.
β-Naphthol, 3-bromo- (CLEMO and SPENCE), 2819.
β-Naphthol-1-sulphonic acid, new reaction of diazosulphonates from (ROWE and LEVIN), 2550; (ROWE, HIMMAT, and LEVIN), 2556.
Naphthylene 1:8-*di*sulphide (PRICE and SMILES), 2372.
α-Naphthylparaconic acid (SHOESMITH and GUTHRIE), 2332.
Neocyanine, and its derivatives (HAMER), 1472.
Neodymium selenate (FRIEND and ROUND), 1820.
"**Ngaio**". See *Myoporum laetum*.
Ngaiol, isomeride and monoxide of (MCDOWALL), 1331.
hydrogenation of (MCDOWALL), 1326.
Ngaione, structure of (MCDOWALL), 1324.
Nitrates, **Nitric acid**, and **Nitrites**. See under Nitrogen.
Nitro-compounds, reduction of, by aromatic ketols (NISBET), 3121.
aromatic, ionisation of, in liquid ammonia (GARNER and GILLBE), 2889.
Nitrogen, active (WILLEY), 1620, 2840.
tervalent, stereochemistry of (JACKSON and KENNER), 573.
Nitrogen *mon*oxide (*nitrous oxide*), photochemical decomposition of (MACDONALD), 1.
*di*oxide (*nitric oxide*), photochemical decomposition of (MACDONALD), 1.
oxides, influence of intensive drying on equilibria of oxygen with (SMITH), 1886.
Nitric acid, reduction of, with magnesium amalgam (NEOGI and NANDI), 1449.
Nitrates, reduction of, with magnesium amalgam (NEOGI and NANDI), 1449.
Nitrous acid, action of, on aminocompounds (TAYLOR), 1099, 1897.
reaction of hydrogen sulphide with (BAGSTER), 2631.
Nitrites, reduction of, with magnesium amalgam (NEOGI and NANDI), 1449.
Hyponitrites, preparation of (NEOGI and NANDI), 1449.
Nitroso-compounds, chemistry of (EARL, ELLSWORTH, JONES, and KENNER), 2697.
Nitrous acid. See under Nitrogen.
Nor-*d*-ψ-ephedrine, and its salts and derivatives (SMITH), 51.
Norpinic acid, attempted synthesis of (CLEMO and WELCH), 2621.

***n*-Octanesulphinic acid**, ferric and sodium salts (FENTON and INGOLD), 3130.
Octoic acid, allyl ester (DEULOFEU), 528.
***n*-Octyloxyacetic acid**, and its *l*-menthyl ester (RULE, HAY, and PAUL), 1357.
Oils, vulcanisation of (KNIGHT and STAMBERGER), 2791.
essential, Indian, constituents of (RAO and SIMONSEN), 2496.
Olefinic compounds, action of bromine water on (READ and REID), 1487.
Oleic acid, methyl ester, oxidation of, by hydrogen peroxide in presence of acetic acid (HILDITCH and LEA), 1576.
Opianic oxime, and its reactions (BRADY, BAKER, GOLDSTEIN and HARRIS), 529.
Optical activity and polarity of substituent groups (RULE, HAY, NUMBERS, and PATERSON), 178; (RULE, HAY, and PAUL), 1347; (BRETSCHER, RULE, and SPENCE), 1493.
inversion, Walden's (RØRDAM), 2447.
Optically active compounds, influence of solvents on rotation of (PATTERSON and MCALPINE), 2472; (PATTERSON and BUCHANAN), 3006.
co-ordination, rotatory dispersion of (WOOD and NICHOLAS), 1727.
Organic compounds, oxidation of, with dichromate (ARK), 46.
Organo-metallic compounds, cyclic (DREW), 506, 511.
Osmium, catalytic hydrogenation by means of (SADIKOV and MIKHAILOV), 438.
Oxalic acid, electrometric titration of, (GANE and INGOLD), 1598.
complex molybdenum salts (SPITTLE and WARDLAW), 2742.
triaminopropane trihydrogen salt (MANN), 898.
Oxidation of organic compounds with dichromate (ARK), 46.
Oximes, isomerism of (BRADY, BAKER, GOLDSTEIN, and HARRIS), 529.
Oxydehydrocorydaline, synthesis of (KOEPFLI and PERKIN), 2989.
Oxygen, heat of adsorption of, on charcoal (MCKIE), 2870.
Oxygen, effect of catalysts on flame speed, infra-red emission and ionisation during combustion of carbon monoxide and (GARNER and JOHNSON), 280.
Oxylupanine, and its chloroplatinate (CLEMO and LEITCH), 1819.

P.

Palladium organic compounds with triaminopropane (MANN), 897.
α- and **β-Parabutylchloral** (CHATTAWAY and KELLETT), 2712.
α- and **β-Parachloral** (CHATTAWAY and KELLETT), 2711.
Parachor and chemical constitution (FREIMAN and SUGDEN), 263; (SUGDEN), 410; (ETRIDGE and SUGDEN), 989.
Passivity of metals (HEDGES), 969.
Pectin of flax plant (HENDERSON), 2117.
Pelargonidin chloride, synthesis of, and its benzoyl derivative (ROBERTSON, ROBINSON, and SUGIURA), 1533.
***cyclo*Pentadienes**, tautomerism of (GOSS and INGOLD), 1268.
Pentamethylene-αε-bis*cyclo*telluripentane 1:1′-*di*bromide, -bisperbromide, -*di*chloride, -*di*chromate, and *di*iodide (MORGAN and BURGESS), 325.
***cyclo*Pentane-1-acetic-1-carboxylic acid**, and its derivatives (BARDHAN), 2600.
β-*cyclo*Pentane*spiro*butyrolactone, and its silver salt (SIRCAR), 902.
***cyclo*Pentane-1:1-diacetic acid**, **αα-*di*-**hydroxy- (GOSS), 1310.
5-*cyclo*Pentane*spirodicyclo*pentan-4-ol-3-one-1-carboxylic acid, and its methyl ester (GOSS), 1309.
5-*cyclo*Pentane*spirocyclo*penten-3-ol-1:4-dione (GOSS), 1308.
Pentane-αε-*di*thiolacetic acid (CHIVERS and SMILES), 701.
β-*cyclo*Pentane*spiro*valerolactone, and its silver salt (SIRCAR), 903.
***cyclo*Pentanone** cyanohydrin, condensation of hexahydrocarbazole and of tetrahydropentindole with (PLANT and RIPPON), 1906.
***r*-*cyclo*Pentylcyanoacetic acid**, ethyl ester (VOGEL), 2021.
***cyclo*Pentylideneacetoacetic acid** (JUPP, KON, and LOCKTON), 1642.
***cyclo*Pentylmalonic acid** (VOGEL), 2022.
Peonidin chloride, synthesis of, and its benzoyl derivative (MURAKAMI and ROBINSON), 1537.
α-Phellandrene, oxidation of (HENRY and PAGET), 75.

Phenacylbenzyldimethylammonium bromide (STEVENS, CREIGHTON, GORDON, and MACNICOL), 3196.
4-Phenacyl-2:3-dimethyl-1:4-benzopyran (HILL), 258.
Phenacylphenyldiethylammonium iodide (STEVENS, CREIGHTON, GORDON, and MACNICOL), 3195.
Phenacyl-β-phenylethyldimethylammonium bromide (STEVENS, CREIGHTON, GORDON, and MACNICOL), 3195.
4-Phenacyl-3-phenyl-2-methyl-1:4-benzopyran (HILL), 258.
1-Phenanthrol, synthesis of (SHOESMITH and GUTHRIE), 2332.
Phenazine, 2-bromo- and 2-chloro- (MCCOMBIE, SCARBOROUGH, and WATERS), 356.
Phenazine series, syntheses in (MCCOMBIE, SCARBOROUGH, and WATERS), 353.
Phenol, *m*-fluoro-, nitration of (HODGSON and NIXON), 1879.
Phenols, irregularity in cryoscopy with (RICHARDSON and ROBERTSON), 1775.
nitrosation of (HODGSON and WIGNALL), 329.
condensation of chloral with (CHATTAWAY and CALVET), 1088.
condensation of dichloroacetaldehyde with (CHATTAWAY and MORRIS), 3241.
equilibria of, with ethylene (PUSHIN and SLADOVIĆ), 837.
compounds of, with lead subacetate solution (GIBSON and MATTHEWS), 596.
reactions of selenium oxychloride with (MORGAN and BURSTALL), 3260.
introduction of the triphenylmethyl group into (BOYD and HARDY), 630.
Phenols, bromoamino-, chloroamino- and and iodoamino-, and their hydrochlorides (HODGSON and KERSHAW), 2704.
halogenoamino-, and their derivatives (HUNTER and BARNES), 2058.
nitro-2-amino-, chloroacetyl and acetyl derivatives (NEWBERY and PHILLIPS), 3043.
Phenolic compounds, acylated, migration of acyl group in (PERKIN and STOREY), 229.
Phenolphthalein, constitution of, and its monomethyl ether (LUND), 1569.
Phenoxides, action of aliphatic esters on (GYNGELL), 1784.
Phenoxselenine, and its salts and derivatives (DREW), 521.
Phenoxtellurine, determination of, in tellurylium compounds (DREW), 509.
Phenoxthionine, and its oxides (DREW), 519.
Phenoxyacetic acid, 2-nitro-4-amino-, acetyl derivative (NEWBERY and PHILLIPS), 3049.
Phenoxyacetic acid 4-arsinic acids, *mono-* and *di*-amino-, acetyl derivatives, and their derivatives (NEWBERY, PHILLIPS, and STICKINGS), 3054.
Phenoxyacetic acid 4-*di*chloroarsine, 2-nitro- (NEWBERY, PHILLIPS, and STICKINGS), 3056.
Phenyl *iso*butyl ether, *p*-chloro- (BRADFIELD and JONES), 3081.
ethyl selenide *di*bromide (EDWARDS, GAYTHWAITE, KENYON, and PHILLIPS), 2302.
methyl selenide *di*hydroxide and *di*halides (EDWARDS, GAYTHWAITE, KENYON, and PHILLIPS), 2300.
p-tolyl selenide *di*bromide and selenoxide (GAYTHWAITE, KENYON, and PHILLIPS), 2283.
Phenyl groups, effects induced by (ASHWORTH and BURCKHARDT), 1791.
Phenylaceto-β-3:4-dimethoxyphenylethylamide, 2′-nitro- (GULLAND and HAWORTH), 585.
Phenylacetonitrile, nitration of (BAKER, COOPER, and INGOLD), 430.
α-Phenyl-β-alkylacrylonitriles, alkylation of (MCRAE and MANSKE), 484.
α-Phenylallyl alcohol, and its *p*-nitrobenzoate (BURTON and INGOLD), 914.
α-Phenylallyl alcohol, α-*p*-chloro-, and its *p*-nitrobenzoate (BURTON), 1655.
Phenylaminoacetic acid, optically active derivatives of (MCKENZIE and WALKER), 646.
Phenylarsenoxide, *mono-* and *di*-aminohydroxy-, and their acetyl derivatives and salts (NEWBERY and PHILLIPS), 2377.
Phenylarsines, aminohydroxy-, acetyl derivatives (NEWBERY and PHILLIPS), 2381.
Phenylarsinic acid, 4-amino-3-hydroxy-, and its acetyl derivative, 2:4-*di*amino-3-hydroxy-, acetyl derivatives, 3-chloro-6-amino-, and its acetyl derivative, 3-chloro-4-nitro-, 2-nitro-4-amino-3-hydroxy-, 4-nitro-3-hydroxy-, and their salts (BALABAN), 809.
5-amino-2:4-*di*hydroxy-, and 5-nitro-5-amino-4-hydroxy-, acetyl derivatives (NEWBERY, PHILLIPS, and STICKINGS), 3058.

Phenylarsinic acid, *di*aminohydroxy- and nitroaminohydroxy-, and their derivatives (BALABAN), 3069.
*di*aminohydroxy- and 2-nitro-5-amino-2-hydroxy-, acetyl derivatives (NEWBERY and PHILLIPS), 2376.
Phenylarsinous acid, 3:5-*di*amino-4-hydroxy-, diacetyl derivative (NEWBERY and PHILLIPS), 2378.
1-Phenylbenzthiazole, quaternary salts of (CLARK), 2316.
10-Phenyl-9-benzylanthracene, 1:5-*di*chloro- (BARNETT and COOK), 570.
Phenylbenzyl-*n*-butylstannic hydroxide, and its salts (KIPPING), 2371.
Phenylbenzylcarbinol, resolution of, and its salts (GERRARD and KENYON), 2564.
10-Phenyl-9-benzyl-9:10-dihydroanthranol, 1:5-*di*chloro- (BARNETT and COOK), 569.
Phenylbenzylstannic chloride (KIPPING), 2368.
Phenylbenzylsulphone, parachor for (FREIMAN and SUGDEN), 268.
Phenylbromoacetamide, 2:4-*di*nitro- (FAIRBOURNE and FAWSON), 1079.
Phenylbromocyanonitromethane, *m*-nitro- (FLÜRSCHEIM and HOLMES), 476.
Phenylbromomalonamic acid, 2:4-*di*nitro-, ethyl ester (FAIRBOURNE and FAWSON), 1079.
3-Phenyl-2-ω-*di*bromomethylquinoxaline (BENNETT and WILLIS), 1974.
Phenyl-*n*-butylstannic chloride (KIPPING), 2371.
β-Phenylbutyric acid, γ-amino-, hydrobromide (JACKSON and KENNER), 1659.
γ-Phenylcarbamyl-*n*-hexylaminopropyl arsinic acid (GOUGH and KING), 2443.
Phenylchloroacetamide, 2:4-*di*nitro- (FAIRBOURNE and FAWSON), 1078.
Phenyl*di*chloroarsine, *mono-* and *di*-aminohydroxy-, and their acetyl derivatives and salts (NEWBERY and PHILLIPS), 2377.
Phenyl-*p*-chlorobenzyl ketone (BENNETT and WILLIS), 1966.
Phenylchlorocyanoacetic acid, 2:4:6-*tri*nitro-, ethyl ester (FAIRBOURNE and FAWSON), 1080.
Phenylchloromalonamic acid, 2:4-*di*nitro-, ethyl ester (FAIRBOURNE and FAWSON), 1078.
Phenylchloromalonic acid, ethyl ester (FLÜRSCHEIM and HOLMES), 1613.
Phenyl-*p*-chlorophenylallyl alcohols, and their derivatives (BURTON and INGOLD), 917.
Phenyl-β-*p*-chlorophenylethyl ketone, and its oxime (BURTON and INGOLD), 918.
3-Phenyl-5-chlorostyryl*cyclo*hexen-1-ones (HEILBRON and HILL), 2868.
3-Phenyl-5-chlorostyryl*cyclo*hexen-1-one-2-carboxylic acids, and *di*chloro-, ethyl esters (HEILBRON and HILL), 2868.
Phenylcyanoacetic acid, nitro-, esters, oxidation of (FAIRBOURNE and FAWSON), 1077.
Phenyl*di*cyanoacetic acid, and *m*-nitro-, ethyl esters (FLÜRSCHEIM and HOLMES), 2237.
Phenylcyanomalonic acid, ethyl ester (FLÜRSCHEIM and HOLMES), 2236.
9-Phenyl-10:10-dibenzyl-9:10-dihydroanthranol, 1-chloro- (BARNETT and COOK), 572.
10-Phenyl-9:9-dibenzyl-9:10-dihydroanthranol (BARNETT and COOK), 571.
3-Phenyl-1:3-dihydrophthalazine-4-acetic acid, 1-hydroxy-3-3′-nitro-, and its derivatives, and 3-3′-nitro-, sodium hydrogen salt (ROWE, HIMMAT, and LEVIN), 2558.
Phenyl β:3-dimethoxystyryl ketone (BENNETT and WILLIS), 1967.
Phenyldithymylmethanes, chloro-, hydroxy- and nitro- (BELL and HENRY), 2226.
Phenyldi-*p*-tolylbenzylstannane (KIPPING), 2370.
Phenylene-1-acetic-α-propionic acids, (TITLEY), 2580.
1:3-Phenylene*di*aminodi-*o*-phenylarsinic acid (GIBSON and JOHNSON), 2211.
Phenylenediacetic acids, esters (TITLEY), 2579.
***o*-Phenylenediamine**, condensations of, with organic acids (PHILLIPS), 2395.
Phenylenedipropionic acids, ethyl esters (TITLEY), 2578, 2583.
***o*-Phenylenemalonamide**, sodium salt (PHILLIPS), 2398.
α- and β-Phenylethanesulphonic acids, barium salts (ASHWORTH and BURCKHARDT), 1798.
β-Phenylethyl bromide, β-hydroxy- (READ and REID), 1488.
β-Phenylethylamine, β-hydroxy- (READ and REID), 1489.
***l*-α-Phenylethylaminopropyl*di*chloroarsine hydrochloride** (GOUGH and KING), 2443.
β-Phenylethyl styryl ketones, chlorohydroxy- (HEILBRON and HILL), 2866.
α-Phenylglucoside hydrate (HICKINBOTTOM), 3147.

β-Phenylglutaric acid, ethyl ester and dihydrazide of (JACKSON and KENNER), 1658.

β-Phenylglutaric acid, β-*o*-hydroxy-, and its disilver salt (SESHADRI), 169.

β-Phenylglutaryl chloride (JACKSON and KENNER), 578.

1-Phenyl-Δ$^{2:4}$-*cyclo*hexadiene, 3:5-*di*chloro-, and its action with chlorine (HINKEL and HEY), 2786.

1-Phenyl*cyclo*hexan-3-one, 4:5:5-*tri*bromo-, and 5-chloro-4:5-*di*bromo- (HINKEL and HEY), 1202, 1204.

1-Phenyl-Δ^{4}-*cyclo*hexen-3-one, 5-bromo- and 5-chloro- (HINKEL and HEY), 1200.

α-Phenyl-β-*n*-hexylacrylonitrile (MCRAE and MANSKE), 490.

α-Phenyl-α′-*n*-hexylsuccinic acid (MCRAE and MANSKE), 490.

Phenylhydrazines, chloronitro- (PLANT and ROSSER), 2461.

2:4:6-trihalogen-substituted, action of chloral with (CHATTAWAY and DALDY), 2736.

3-Phenylindole, *o*-amino-, and its salts, and *o*-nitro- (KERMACK and SLATER), 39.

3-Phenylindole-2-carboxylic acid, *o*-nitro-, and its salts (KERMACK and SLATER), 38.

Phenyl*di*iodoarsine, *mono-* and *di*aminohydroxy-, and 3-nitro-4-hydroxy-5-amino-, and their acetyl derivatives and salts (NEWBERY and PHILLIPS), 2377.

Phenylmethanetricarboxylic acid, and *o*-nitro-, ethyl esters (FLÜRSCHEIM and HOLMES), 1612.

Phenylmethoxychloroarsines, aminohydroxy- (NEWBERY and PHILLIPS), 2380.

Phenyl β-methoxy-*p*-chlorostyryl ketone (BENNETT and WILLIS), 1966.

1-Phenyl-4-methyl-3:4-dihydro*iso*quinoline, 4-amino-, and its derivatives (JACKSON and KENNER), 1660.

3-Phenyl-1-methylindole, *o*-amino-, and its salts and acetyl derivative, and *o*-nitro- (KERMACK and SLATER), 45.

3-Phenyl-1-methylindole-2-carboxylic acid. 3-nitro-, and its salts (KERMACK and SLATER), 43.

3-Phenylmethylmethyleneamino-2:4-diketo-5-ethyltetrahydrothiazole 2-phenylmethylmethylenehydrazone (STEPHEN and WILSON), 1418.

3-Phenylmethylmethyleneamino-2:4-diketo-5-methyltetrahydrothiazole 2-phenylmethylmethylenehydrazone (STEPHEN and WILSON), 1418.

3-Phenylmethylmethyleneamino-2:4-diketo-5-phenyltetrahydrothiazole 2-phenylmethylmethylenehydrazone (STEPHEN and WILSON), 1418.

Phenylmethylnitrosoamine, 4-bromo-2:6-*di*nitro- (CLEMO and SMITH), 2421.

Phenylmethylphosphinanilide (GIBSON and JOHNSON), 96.

Phenylmethylphosphinic acid, esters (GIBSON and JOHNSON), 96.

Phenylmethylphosphinyl chloride (GIBSON and JOHNSON), 95

1-Phenyl-3-methyl-5-pyrazolone-4-β-propionic acid, ethyl ester (CLEMO and WELCH), 2628.

2-Phenyl-6-methyl 4-pyrone, salts and derivatives of (GIBSON and SIMONSEN), 2307.

Phenylmethylselenetine bromide, preparation of, and its action on heating (EDWARDS, GAYTHWAITE, KENYON, and PHILLIPS), 2297.

Phenylmethylsulphone, 2-iodo- (BARBER and SMILES), 1144.

2-Phenyl-*peri*-naphtha-1:3-dithiane (PRICE and SMILES), 2374.

2-Phenylnaphthylene-1:3-diamine, derivatives of (GIBSON, KENTISH, and SIMONSEN), 2131, 2138.

Phenylnitromethane, constitution and substitution of, and its derivatives (FLÜRSCHEIM and HOLMES), 453.

2-(β-Phenyl-*p*-nitrostyryl)quinoxaline (BENNETT and WILLIS), 1972.

Phenylopianic oxime, 2:4-*di*nitro- (BRADY, BAKER, GOLDSTEIN, and HARRIS), 536.

3-Phenyl-2-phenylacetoxymethylquinoxaline, and 2-*p*-chloro- (BENNETT and WILLIS), 1974.

Phenyl β-phenylethyl ketone semicarbazone (SHOPPEE), 2571.

Phenyl β-phenylethyl ketone, *p*-chloro-, and its oxime (BURTON and INGOLD), 918.

Phenylphthalazones, amino- and nitro-, and their derivatives (ROWE and LEVIN), 2550; (ROWE, HIMMAT, and LEVIN), 2556.

***N*-Phenylphthalimidine**, 3′-amino- and 3′-hydroxy-, and their derivatives (ROWE, HIMMAT, and LEVIN), 2560.

β-Phenylpropane, αγ-*di*amino-, and its derivatives (JACKSON and KENNER), 1657.

Phenylpropiolic acid, addition of "bromine chloride" to (HANSON and JAMES), 2979.

and its ethyl ester, nitration of (BAKER, COOPER, and INGOLD), 429.

β-Phenylpropionic acid, *αα*ββ-*tetra*chloro-, and *αββ-tri*chloro-*α*-bromo- (HANSON and JAMES), 2985.
allo-**β-Phenylpropionic acid**, β-chloro-*α*-bromo- (HANSON and JAMES), 1958.
4-Phenyl-2-pyrrolidone, and its derivatives (JACKSON and KENNER), 1659.
Phenylselenoglycollic acid *di*bromide (EDWARDS, GAYTHWAITE, KENYON, and PHILLIPS), 2298.
α-Phenylstyryl benzyl ketone, 2-hydroxy-, and its semicarbazone (DICKINSON, HEILBRON, and O'BRIEN), 2080.
3-Phenyl-2-styrylquinoxaline, and its nitro-derivatives (BENNETT and WILLIS), 1972.
3-Phenyltetrahydrophthalazine-4-acetic acid, 1-hydroxy-3-3′-amino-, and its acetyl derivative (ROWE, HIMMAT, and LEVIN), 2559.
Phenylthymylacetonitriles, hydroxy- (BELL and HENRY), 2225.
γ-Phenyl-α-*p*-tolylallyl alcohol, and its acetates (BURTON and INGOLD), 916.
Phenyl-*p*-tolylbenzylstannic hydroxide, and its salts (KIPPING), 2370.
Phenyl β-*p*-tolylethyl ketone, and its ketoxime (BURTON and INGOLD), 921.
Phenyltribenzylstannane (KIPPING), 2367.
Phenyltrimethylarsonium picrate, *m*-nitro- (INGOLD, SHAW, and WILSON), 1285.
Phenyltrimethylphosphonium picrate, and *m*-nitro- (INGOLD, SHAW, and WILSON), 1283.
Phenyltrimethylstibonium picrate, and *m*-nitro- (INGOLD, SHAW, and WILSON), 1283.
Phloroglucinolphenolphthalein 2′:4′:6′-trimethyl ether (LUND), 1575.
Phloroglucinolphthalein hexamethyl ether (LUND), 1573.
Phorone, ring-chain valency tautomerism in derivatives of (SUGDEN), 410.
substitution in cyclic derivatives of (INGOLD and SHOPPEE), 1868; (SHOPPEE), 2360.
Phorone, *aa-di*bromo-, preparation and reduction of (INGOLD and SHOPPEE), 385.
Phosphonium salts, aromatic, nitration of (INGOLD, SHAW, and WILSON), 1280.
Phosphorus, spectrum of glow of (EMELÉUS and PURCELL), 628.
Phosphorus *tri*oxide, pure, preparation and properties of (MILLER), 1847.
oxychloride. See Phosphoryl chloride.
Phosphorus organic compounds (GIBSON and JOHNSON), 92.
Phosphoryl chloride, action of, on diaryl*iso*propyl alcohols in pyridine (BOYD and LADHAMS), 215.
Phthalic acid, separation of homophthalic acid from (POOLE), 1378.
Phthalic acid, 4-bromo-, preparation of (BAKER), 2829.
n- and *l*-**α-Phthalimidophenylacetic acids** (MCKENZIE and WALKER), 648.
Phthaloximes, sodium salts, methylation of (BRADY, BAKER, GOLDSTEIN, and HARRIS), 538.
Pimelic acid, electrometric titration of (GANE and INGOLD), 1598.
l-menthyl hydrogen esters (RULE, HAY, and PAUL), 1358.
Pinus longifolia, Indian turpentine from (PILLAY and SIMONSEN), 359.
NN′-**Piperazinedi-ββ′-ethylarsinic acid** *di*hydrochloride (GOUGH and KING), 2436.
γ-Piperazinopropylarsinic acid, *di*-hydrochloride and benzoyl derivative of (GOUGH and KING), 2445.
Piperidine, interaction of, with nitro- and halogenonitro-derivatives of xanthone and diphenylene oxide (LE FÈVRE), 3249.
2′-Piperidino-2-acetoxybenzophenone, 5:5′-*di*nitro- (LE FÈVRE), 3251.
β-Piperidinoethylarsinic acid hydrochloride (GOUGH and KING), 2436.
β-Piperidinoethyl*di*chloroarsine hydrochloride (GOUGH and KING), 2436.
β-Piperidinoethyl*di*iodoarsine hydriodide (GOUGH and KING), 2436.
2′-Piperidino-2-hydroxybenzophenone, 5:5′-*di*nitro- (LE FÈVRE), 3250.
γ Piperidinopropylarsinic acid, and its hydrochloride (GOUGH and KING), 2443.
γ-Piperidinopropyl*di*chloroarsine hydrochloride (GOUGH and KING), 2444.
Piperonylidenethebainone (GULLAND), 705.
Piperylene, catalytic hydrogenation of (LEBEDEV and YAKUBCHIK), 2200.
Pipette, new (RIDYARD), 749.
Platinicyanides. See Cyanoplatinates.
Platinum, catalytic, influence of arsenic on, in oxidation of sulphur dioxide (MAXTED and DUNSBY), 1600.
colloidal (PENNYCUICK and BEST); 551; (PENNYCUICK), 2108.
Platinum alloys with mercury, adsorption of gases on (SMITH), 2045.
Hexahydroxyplatinic acid (PENNYCUICK and BEST), 560.
in colloidal platinum solutions (PENNYCUICK), 2108.

Platinum organic compounds with $\alpha\beta\gamma$-triaminopropane (MANN), 890.
Platinum salts, complex, with β-methyltrimethylenediamine (MANN), 1261.
Platinum electrodes. See under Electrodes.
Polarity and optical activity of substituent groups (RULE, HAY, NUMBERS, and PATERSON), 178; (RULE, HAY, and PAUL), 1347; (BRETSCHER, RULE, and SPENCE), 1493.
Polycyclic compounds, chemistry of, in relation to their homocyclic unsaturated isomerides (GOSS), 1306.
Polygalacturonic acid (HENDERSON), 2123.
Polynuclear compounds, catalytic production of (CLEMO and SPENCE), 2811.
Polysaccharides (HAWORTH and LEARNER), 619; (HAWORTH, HIRST, and WEBB), 2681; (DREW and HAWORTH), 2690.
Potassium chloride, density and viscosity of saturated solutions of, in hydrochloric acid (INGHAM), 1917.
chromate and *di*chromate, action of, with cuprous chloride in sodium chloride solution (VENN and EDGE), 2142.
*di*chromate, parachor for (FREIMAN and SUGDEN), 268.
sulphate, equilibrium of, with cobalt sulphate and water (CAVEN and JOHNSTON), 2506.
Potential, electrokinetic, between the solid and liquid states of a substance (FAIRBROTHER and WORMWELL), 1991.
Propane, $\alpha\gamma$-di-*p*-toluenethiolsulphonate (CHIVERS and SMILES), 700.
Propane, $\alpha\beta\gamma$-*tri*amino-, complex palladium and platinum salts with (MANN), 890.
Propane-$\alpha\gamma$-dipyridinium salts (GOUGH and KING), 2447.
Propane-$\alpha\alpha\gamma$-tricarboxylic acid (LENNON and PERKIN), 1524.
Propanol, β-nitro-, sodium salt (EARL, ELLSWORTH, JONES, and KENNER), 2702.
Propionylacetophenone, and its derivatives (LOVETT and ROBERTS), 1976.
Propoxyacetic acid, *l*-menthyl ester (RULE, HAY, and PAUL), 1355.
α-*iso*Propylacetonedicarboxylic acid, and its ethyl ester (HARIHARAN, MENON, and SIMONSEN), 435.
1-*n*-Propylamino-3-methylbenzthiazole, and its derivatives, and 5-bromo- (HUNTER and STYLES), 3026.
γ-*n*-Propylaminopropylarsinic acid, and its hydrochloride (GOUGH and KING), 2441.
γ-*n*-Propylaminopropyl*di*chloroarsine hydrochloride (GOUGH and KING), 2442.
9-*n*-Propylanthracene, 2-chloro- (BARNETT and WILTSHIRE), 1824.
Propylarsinic acid, γ-amino-, γ-chloro- and γ-hydroxy-, and their salts (GOUGH and KING), 2439.
Propyl*di*chloroarsine, γ-chloro- (GOUGH and KING), 2439.
γ-*iso*Propylcyanoacetic acid, ethyl ester, preparation of (VOGEL), 2019.
***l*-*iso*Propylsuccinic acid**, and its salts and derivatives (HENRY and PAGET), 78.
α-*iso*Propylglutaconic acids, isomeric, and their ethyl ester (HARIHARAN, MENON, and SIMONSEN), 431.
α-*iso*Propylglutaric acid, β-chloro-, α-cyano-, and δ-hydroxy-, ethyl esters (HARIHARAN, MENON, and SIMONSEN), 434.
***iso*Propylideneacetoacetic acid**, ethyl ester, and its semicarbazone (JUPP, KON, and LOCKTON), 1642.
***iso*Propylidenemalonic acid**, ethyl ester (VOGEL), 2018.
***iso*Propylmalonic acid**, preparation of (VOGEL), 2020.
4-*iso*Propylstyryl nonyl ketone, and its dimeride (HEILBRON and IRVING), 2223.
Prototropic compounds, absorption spectra of (LOWRY, MACCONKEY, and BURGESS), 1333.
Pseudaconine, and its tetra-acetyl derivative (HENRY and SHARP), 1112.
Pseudaconitine, and its salts and derivatives (HENRY and SHARP), 1111; (SHARP), 3094.
Δ^1-Pulegonylacetone, and its semicarbazone (JUPP, KON, and LOCKTON), 1643.
Pump, gas circulating (BARR), 3293.
Purpurin, and its acetyl derivatives, and their methyl ethers (PERKIN and STOREY), 237.
Purpuroxanthin, and its 3-acetyl derivative, and their methyl ethers (PERKIN and STOREY), 238.
Pyridine, inhibition of esterification by (BAILEY), 1204.
nuclear fission of, by oxidation with potassium permanganate (SHAW and WILKIE), 1377.
additive compound of phosphoryl chloride and (BOYD and LADHAMS), 218.

Pyropseudaconine, and its derivatives (SHARP), 3098.
Pyropseudaconitine (SHARP), 3097.
Pyroterebic acid, synthesis of, and its derivatives (GOLDBERG and LINSTEAD), 2343.
1-2-Pyrrolidone-5-carboxyanilide, and its derivatives (GRAY), 1265.
Pyrylium salts, synthesis of (ROBERTSON and ROBINSON), 1526; (ROBERTSON, ROBINSON, and SUGIURA), 1533; (MURAKAMI and ROBINSON), 1537; (BRADLEY and ROBINSON), 1541.

Q.

Quartz, rotatory dispersion of (WOOD and NICHOLAS), 1735.
adsorption of vapours on (SMITS), 2952.
2-Quinizarinphenylsulphone-2′-carboxylic acid (PRICE and SMILES), 3157.
Quinol, 2:6-*di*chloro-, condensation of chloral with (CHATTAWAY and CALVET), 2913.
Quinoline, 2-iodo-, ethiodide and methiodide (HAMER), 209.
Quinoxaline, 2:3-*di*hydroxy-, and its sodium salt (PHILLIPS), 2397.
Quinoxalines, reduced, stereochemistry of (GIBSON, NUTLAND, and SIMONSEN), 108.
substituted, steric hindrance in reactions of (BENNETT and WILLIS), 1960.
Quinoxalinearsinic acids, 2:3-*di*hydroxy- (PHILLIPS), 3139.
Quinoxalinecyclopentane, benzylidene derivatives (BENNETT and WILLIS), 1973.

Racemates, influence of constitution on stability of (FINDLAY and CAMPBELL), 1768.
Racemic mixtures, spontaneous resolution of (ANDERSON and HILL), 993.
Radicals, electronic affinities of (ZAKI), 983.
Reactions, inhibition of (BAILEY), 3256.
bimolecular, velocity coefficient for, in solution (NORRISH and SMITH), 129.
elimination, influence of poles and polar linkings on (INGOLD and VASS), 3125; (FENTON and INGOLD), 3127.
Resorcinol dimethyl ethers, 5-chloro-2- and -4-nitro- (HODGSON and WIGNALL), 331.
Resorcinol, 2:4:6-*tri*nitro-5-amino-, and its ethers (FLÜRSCHEIM and HOLMES), 3044.
Resorcinolphenolphthalein, 2′:4′-dimethyl ether (LUND), 1575.
Resorcinolphthalein tetramethyl ether (LUND), 1574.
Rhodioxalic acid, potassium salt, rotatory dispersion of (WOOD and NICHOLAS), 1736.
Rotation and chemical constitution (GERRARD and KENYON), 2564; (HOLLOWAY, KENYON, and PHILLIPS), 3000.
of optically active compounds, influence of solvents on (PATTERSON and MCALPINE), 2472; (PATTERSON and BUCHANAN), 3006.
Rubidium hyponitrite (NEOGI and NANDI), 1452.

Safrole *di*bromide (READ and REID), 1490.
*iso***Safrole**, action of bromine water on (READ and REID), 1490.
Salicylaldehyde, 5-chloro-3-nitro- and 3:5-*di*nitro- (LOVETT and ROBERTS), 1978.
Salicylic acid, ethyl and methyl esters, aluminium derivatives (BURROWS and WARK), 228.
methyl ester, copper and nickel derivatives of (DOAK and PACKER), 2763.
Salts, complex (RILEY), 2985.
uni-univalent, conductivy of, in benzonitrile (MARTIN), 3270.
Salting-out effect (CARTER and HARDY), 127.
Sebacic acid, *l*-menthyl hydrogen ester (RULE, HAY, and PAUL), 1358.
Selenitopentammine cobalt salts. See under Cobalt.
Selenium, quadrivalent (GAYTHWAITE, KENYON, and PHILLIPS), 2280, 2287; (EDWARDS, GAYTHWAITE, KENYON, and PHILLIPS), 2293.
Selenium oxychloride, reactions of phenols with (MORGAN and BURSTALL), 3260.
*tetra*fluoride (PRIDEAUX and COX), 1603.
oxyfluoride (PRIDEAUX and COX), 739.
*di*oxide, reaction of hydrogen chloride with (PARKER and ROBINSON), 2853.
Selenious acid, reduction of (CLARK), 2388.

Selenocyanic acid, aromatic esters, nitro- and nitrohalogeno-derivatives (CHALLENGER and PETERS), 1364.
4-Selenocyanoacetanilide, 2-nitro- (CHALLENGER and PETERS), 1375.
4-Selenocyanoaniline, 2-nitro- (CHALLENGER and PETERS), 1375.
Selenocyanobenzene, *p*-thiocyano-, preparation and nitration of (CHALLENGER and PETERS), 1372.
Selenophen, preparation of (BRISCOE, PEEL, and ROBINSON), 2628.
and its halogen derivatives (BRISCOE and PEEL), 1741.
Selenotoluene, *p*-bromo-, *di*bromide (EDWARDS, GAYTHWAITE, KENYON, and PHILLIPS), 2299.
Semi-pinacolin, cyclic, and its derivatives (COOK), 58.
Silicon:—
Disilicon *hexa*chloride, action of, on ether (KIPPING and THOMPSON), 1989.
commercial, titanium tetrachloride in (KIPPING and THOMPSON), 1377.
Silicon organic compounds (KIPPING and MURRAY), 1427; (STEELE and KIPPING), 1431.
Silver, solution tension of, in non-aqueous solvents (KOCH), 269.
Silver *di*chromate, precipitation of, in gelatin (HEDGES and HENLEY), 2715.
*sub*fluoride, crystal structure of (TERREY and DIAMOND), 2820.
nitrate cells. See under Cells.
Sodium alloys with tin (HUME-ROTHERY), 947.
Sodium chloride, density and viscosity of saturated solutions of, in hydrochloric acid (INGHAM), 1917.
sulphate, equilibria of, with manganese sulphate and water and with zinc sulphate and water (CAVEN and JOHNSTON), 2506.
Solubility in mixed solvents (GREGG-WILSON and WRIGHT), 3111.
Solutions, equilibria in (WYNNE-JONES), 1230; (SOPER), 1233.
Solvents, selective action of (GREGG-WILSON and WRIGHT), 3111.
Sorbic acid, hydrogenation of (EVANS and FARMER), 1648; (GOLDBERG and LINSTEAD), 2343.
Sorbitol, thallium compound of (MENZIES and KIESER), 190.
Spectra and atoms (FOWLER), 764.
absorption, of phototropic compounds (LOWRY, MACCONKEY, and BURGESS), 1333.
Stannic oxide. See under Tin.
Starch, acetylation and methylation of (HAWORTH, HIRST, and WEBB), 2681.
Stereoisomerism in polycyclic systems (PERKIN and PLANT), 639, 2583.
Sterol group (HEILBRON, MORTON, and SEXTON), 47; (HEILBRON and SEXTON), 347.
Stibonium salts, aromatic, nitration of (INGOLD, SHAW, and WILSON), 1280.
Strontium hyponitrite (NEOGI and NANDI), 1454.
oxide, and its hydrates, action of bromine on (DUNNICLIFF, SURI, and MALHOTRA), 3106.
Strychnine, constitution of (FAWCETT, PERKIN, and ROBINSON), 3082.
Styrene, addition of polar reagents to (ASHWORTH and BURCKHARDT), 1791.
action of bromine water on (READ and REID), 1488.
Styrenes, ω-bromo- and ω-chloro-nitro-, alkaline hydrolysis of (DANN, HOWARD, and DAVIES), 605.
Styryl alkyl ketones, isomerism of (McGOOKIN and SINCLAIR), 1170.
Styryl *iso*butenyl ketone, 2-hydroxy- (McGOOKIN and SINCLAIR), 1176.
Styryl *tert.*-butyl ketone, 2-hydroxy- (McGOOKIN and SINCLAIR), 1176.
2-Styryl-3:6-dimethylquinoxaline, 2-*m*-nitro- (BENNETT and WILLIS), 1972.
Styryl ethyl ketone, 4-hydroxy- (McGOOKIN and SINCLAIR), 1175.
Styryl ketones, intermolecular condensation of (HEILBRON and IRVING), 2323.
Styryl ketones, *o*-hydroxy-, condensation of β-ketonic esters with (HILL), 256.
2-Styryl-3-methylchromones, nitro- (NISBET), 3122.
Styryl methyl ketone, 3-chloro- (HEILBRON and HILL), 2867.
Styryl methyl ketones, hydroxy- (McGOOKIN and SINCLAIR), 1174.
2-Styrylmethylquinolines, and their *di*nitro-derivatives (BENNETT and WILLIS), 1973.
2-Styryl-3-methylquinoxaline, nitro-derivatives (BENNETT and WILLIS), 1969, 1970.
Styryl nonyl ketone, and chloro- and hydroxy-, and their derivatives (HEILBRON and IRVING), 2323.
Styryl propyl ketones, hydroxy- (McGOOKIN and SINCLAIR), 1175.
Styrylpyrylium salts (DICKINSON, HEILBRON, and O'BRIEN), 2077.
2-Styrylquinoline, 2:4-*di*nitro- (BENNETT and WILLIS), 1973.

2-Styrylquinoxaline, nitro-derivatives (BENNETT and WILLIS), 1967.
Suberic acid, electrometric titration of (GANE and INGOLD), 1598.
catalytic decomposition of (VOGEL), 2032.
l-menthyl hydrogen ester (RULE, HAY, and PAUL), 1358.
Suberone, preparation of (VOGEL), 2032.
Substance, $C_9H_{15}O_3N$, from potassium cyanide and methylmesityl oxide (BARDHAN), 2615.
$C_{20}H_2O_2N_2$, from *o*-nitrobenzyl chloride and ethyl acetoacetate (KERMACK and SLATER), 36.
$C_{26}H_{..}O_8$, from the action of perbenzoic acid on deoxytrimethylbrazilone (PERKIN, RÂY, and ROBINSON), 1509.
$C_{27}H_{18}O_2$, from 2-hydroxy-α-naphthaldehyde and ω-phenylacetylacetophenone (LOVETT and ROBERTS), 1979.
$C_{21}H_{46}O$, from reduction of campnospermonyl methyl ether (JONES and SMITH), 69.
$C_{22}H_{46}O_2$, from reduction of campnospermonol (JONES and SMITH), 69.
$C_{..}H_{50}O$, from reduction of campnospermonyl methyl ether (JONES and SMITH), 69.
Substitution in aromatic compounds (FLÜRSCHEIM and HOLMES), 448, 453, 1607, 2230; (INGOLD and ROTHSTEIN), 1217.
adjacent (HODGSON and KERSHAW), 191.
Succinic acid, electrometric titration of (GANE and INGOLD), 1598.
Succinic acid, *di*chloro-, ethyl ester, rotation dispersion of (WOOD and NICHOLAS), 1691.
Sugars, relation of ring-chain tautomerism to mutarotation of (BAKER), 1583.
of the mannose series, structure and optical relations of (HAWORTH and HIRST), 1221.
-Sulphinobenzoic acid, and its *di*chloride (PRICE and SMILES), 2858.
1-Sulphinonaphthalene-8-sulphonic acid, and its sodium salt (PRICE and SMILES), 2373.
Sulphonal, parachor for (FREIMAN and SUGDEN), 265.
Sulphonamides, aromatic, action of diazo-salts on (KEY and DUTT), 2035.
Sulphones, parachor for (FREIMAN and SUGDEN), 263.
Sulphur, equilibrium of, with its monochloride (HAMMICK and ZVEGINTZOV), 1785.
Sulphur, liquid, inner equilibrium in (HAMMICK, COUSINS, and LANGFORD), 797.
phosphorescent combustion of (EMELÉUS), 1942.
reaction of acetylene on, up to 650° (PEEL and ROBINSON), 2068.
determination of, in iron sulphides (ROBINSON, SAYCE, and STEVENSON), 813.
Sulphur *di*oxide, poisoning of catalytic platinum by arsenic in oxidation of (MAXTED and DUNSBY), 1600.
Syringoylacetic acid, ethyl ester (BRADLEY and ROBINSON), 1554.
Systems, symmetrical triad, mobility of (SHOPPEE), 2567.

T.

Tartaric acid, esters, and their derivatives, anomalous rotatory dispersion of (WOOD and NICHOLAS), 1671.
butyl and propyl esters, rotatory dispersion of (AUSTIN), 1831.
triethylenediaminenickel salt (BUCKNALL and WARDLAW), 2741.
rotatory dispersion of derivatives of (AUSTIN), 1825, 1831.
Tautomerism, mechanism of, and its effect on mobility and equilibrium (BAKER), 1583, 1979.
five-carbon intra-annular (GOSS), 1306.
mobile-anion (BURTON and INGOLD), 904; (BURTON), 1650.
mobile hydrogen (SHOPPEE), 1662.
and ring-chain (SHOPPEE), 2360.
ring-chain, and mutarotation of sugars (BAKER), 1583.
ring-chain valency and mobile-hydrogen (INGOLD and SHOPPEE), 365, 1868.
three-carbon (BURTON and INGOLD), 904; (DICKINS, HUGH, and KON), 1630; (GOLDBERG and LINSTEAD), 2343; (ABBOTT, KON, and SATCHELL), 2514.
*cyclo*Telluripentane *di*bromide, *di*chloride, *di*iodide, and *di*oxide (MORGAN and BURGESS), 325.
Tellurium *di*oxide, reaction of hydrogen chloride with (PARKER and ROBINSON), 2853.
Tellurium organic compounds, quadrivalent, molecular structure of (LOWRY, GOLDSTEIN, and GILBERT), 307.
Tellurylium compounds (DREW), 506.
*cyclo*Telluropentane (MORGAN and BURGESS), 321.

*cyclo*Telluropentane, molecular coefficients and extinction coefficients of derivatives of (GILBERT and LOWRY), 2658.

Terephthalic acid, *d*-β-octyl hydrogen ester (RULE, HAY, NUMBERS, and PATERSON), 182.

Terpenes, cyclic, oxidation of, with Beckmann's chromic acid mixture (HENRY and PAGET), 70.

Tetra-acetylglucose, anilides of, and their mutarotation (BAKER), 1589.

ω-*O*-Tetra-acetyl-β-glucosidoxy-4-acetoxyacetophenone (ROBERTSON and ROBINSON), 1466.

ω-*O*-Tetra-acetyl-β-glucosidoxy-4-benzoyloxyacetophenone (ROBERTSON and ROBINSON), 1466.

3-*O*-Tetra-acetyl-β-glucosidoxy-7-hydroxy-5-benzoyloxy-4'-acetoxyflavylium chloride (ROBERTSON and ROBINSON), 1467.

ω-*O*-Tetra-acetyl-β-glucosidoxy-4-methoxyacetophenone (ROBERTSON and ROBINSON), 1467.

2:3:4:6-Tetra-acetyl β-*iso*propylglucoside (HICKINBOTTOM), 3146.

Tetrabenzylsilicane, preparation of (STEELE and KIPPING), 1431.

Tetracarboxylic acids, *di*bromo-, esters, action of sodium ethyl malonate, sodium ethyl ethanetetracarboxylate and similar substances on (LENNON and PERKIN), 1513.

Tetraethylpiperazinium salts (GOUGH and KING), 2438.

Tetrahydrobenzarsazinephenarsazines, *di*bromo-, *di*chloro-, and *di*iodo- (GIBSON and JOHNSON), 2211.

Tetrahydrocarbazole, derivatives of (PLANT and ROSSER), 2454.

Tetrahydrocarbazole, 6-chloro-, and 6-chloronitro-, and their acetyl and benzoyl derivatives (PLANT and ROSSER), 2462.

Tetrahydrocarbazole-9-carboxylic acid, 6-chloro-, and 6-chloro-5(or 7)-nitro-, ethyl esters (PLANT and ROSSER), 2463.

1-(9'-Tetrahydrocarbazyl)*cyclo*pentane-1-carboxylic acid (PLANT and RIPPON), 1910.

3:4:5:6-Tetrahydro-4-carboline (ASHLEY and ROBINSON), 1376.

2:3:4:5-Tetrahydroheptindole, and its picrate, and 7-bromo- (PERKIN and PLANT), 2586.

Tetrahydronaphthacarbazoles, and their derivatives (OAKESHOTT and PLANT), 1840.

Tetrahydrongaiol, reduction of (MCDOWALL), 1330.

Tetrahydropentindole, and its derivatives (PLANT and RIPPON), 1911.
condensation of, with *cyclo*pentanone cyanohydrin (PLANT and RIPPON), 1906.

1-(8'-Tetrahydropentindyl)-1-cyano-*cyclo*pentane, and its derivatives (PLANT and RIPPON), 1912.

1:4:5:6-Tetrahydropyrimidine-2-thioglycollic acid, ethyl ester (STEPHEN and WILSON), 1420.

Tetrakisethylenethiocarbamidopalladous salts (MORGAN and BURSTALL), 154.

6:7:3':4'-Tetramethoxy-1-benzyl-3:4-dihydro*iso*quinoline, 2-nitro-, and its salts (GULLAND and HAWORTH), 1836.

6:7:3':4'-Tetramethoxy-1-benzyl-2-methyltetrahydro*iso*quinoline, 2'-amino-, and its dihydrochloride (GULLAND and HAWORTH), 1836.

6:7:3':4'-Tetramethoxy-9-methyl-2'-carbomethoxy-3:4-dihydroprotopapaverine (KOEPFLI and PERKIN), 2999.

3:4:5:8-Tetramethoxyphenanthrene, and its picrate and 9-carboxylic acid (GULLAND and VIRDEN), 1486.

2:3:5:6-Tetramethoxyphenanthrene-8-carboxylic acid (BARGER and SILBERSCHMIDT), 2922.

7:8:2':5'-Tetramethoxy-3-phenylcarbostyril (GULLAND and VIRDEN), 1484.

3:4:2':5'-Tetramethoxy-α-phenylcinnamic acids, 2-amino- and 2-nitro-, isomeric (GULLAND and VIRDEN), 1482.

2:3:5:6-Tetramethoxy-8-vinylphenanthrene (BARGER and SILBERSCHMIDT), 2922.

ββ'β'-Tetramethyladipic acid, synthesis of (VOGEL), 2010.

pp'-Tetramethyl*di*aminodiphenyl[glyoxalinyl-4(5)-]methane (HUBBALL and PYMAN), 26.

Tetramethylammonium molybdenyl *tetra*chloride (JAMES and WARDLAW), 2738.

ββγγ-Tetramethylbutane-αδ-dicarboxylic acid, monoamide and ethyl ester of (VOGEL), 2019.

1:6:1':6'-Tetramethyl-ψ-cyanine iodide (HAMER), 211.

Tetramethylglucose, action of catalysts in mutarotation of anilides of (BAKER), 1979.

ααββ-Tetramethylglutaric acid, γγ'-*di*hydroxy-, methyl hydrogen ester, lactone (INGOLD and SHOPPEE), 406.

ααββ-Tetramethylglutaric anhydride and imide (INGOLD and SHOPPEE), 396.

1:3:3:1′-Tetramethylindo-ψ-cyanine iodide (HAMER), 214.
2:2:3:3-Tetramethyl*cyclo*pentanedione, 1:1-*di*bromo-, 1:1-*di*chloro-, and 1-chloro-1-bromo- (INGOLD and SHOPPEE), 409.
3:3:4:4-Tetramethyl*cyclo*pentane-1:2-dione, derivatives of (INGOLD and SHOPPEE), 396.
2:2:3:3-Tetramethyl-[0,1,2]-*dicyclo*pentan-4-ol-5-one, and 1-bromo-, and 1-chloro-, and their derivatives, and 1-cyano- (INGOLD and SHOPPEE), 386.
2:2:3:3-Tetramethyl*cyclo*pentanone, and its derivatives (INGOLD and SHOPPEE), 397.
2:2:3:3-Tetramethyl*cyclo*pentan-5(or 1)-one, 1(or 5)-hydroxy-, tautomerism of, and its derivatives (SHOPPEE), 1662.
3:3:4:4-Tetramethyl*cyclo*pentanone, and its derivatives (INGOLD and SHOPPEE), 390.
3:3:4:4-Tetramethyl*cyclo*pentanone, *di*bromo- (SHOPPEE), 2363.
2:2:3:3-Tetramethyl*cyclo*pentanone-oxime, 5-hydroxy-, acetyl derivative (INGOLD and SHOPPEE), 1871.
Tetramethyl*cyclo*pentylamines, and hydroxy-, and their salts and acetyl derivatives (INGOLD and SHOPPEE), 392, 398.
Tetraphenylmethane-3-carboxylic acid, 5-bromo-4-hydroxy-, 4-hydroxy-, and its acetyl derivative, and 5-nitro-4-hydroxy- (BOYD and HARDY), 634.
Tetraphenylstannane, preparation of (KIPPING), 2367.
Thallium compounds, use of, in organic chemistry (MENZIES and KIESER), 186.
Thallium salts, molecular structure of (BERRY and LOWRY), 1748.
Thallium *tri*iodide, structure of, and its derivatives (BERRY, LOWRY, and GOLDSTEIN), 1748.
Thallium organic compounds with polyhydroxy-compounds (MENZIES and KIESER), 186.
Thallium alkyl halides (BERRY, LOWRY, and GILBERT), 1757.
Thallium dialkyls, and their chelate compounds with aldehydes and ketones (MENZIES, SIDGWICK, CUTLIFFE, and FOX), 1288.
Thebenine, constitution of (GULLAND and VIRDEN), 921.
Thiazole derivatives (STEPHEN and WILSON), 1415.
Thiocarbonic acids. See Carbonic acid under Carbon.
Thiocyanic acid, complex molybdenum salts of (JAMES and WARDLAW), 2726.
aromatic esters, nitro- and nitrohalogeno-derivatives (CHALLENGER and PETERS), 1364.
Thiophen, production of, from acetylene and carbon disulphide (BRISCOE, PEEL, and ROBINSON), 2857.
Thioxanthone *di*oxide, hydroxy-derivatives, and their derivatives (PRICE and SMILES), 3154.
Thorium *di*oxide, mixed catalysts of ceria and (GOGGS), 2667.
Thymolaldehydes, synthesis of (BELL and HENRY), 2219.
Thymoquinone *di*semicarbazone (HENRY and PAGET), 80.
Thymylcarvacrylacetonitrile, and its diacetyl derivative (BELL and HENRY), 2224.
Tin alloys with sodium (HUME-ROTHERY), 947.
Tin:—
Stannic oxide, interaction of acids and neutral salts with (GHOSH), 3027.
Tin organic compounds, optically active (KIPPING), 2365.
Titanium *tetra*chloride, occurrence of, in commercial disilicon hexachloride (KIPPING and THOMPSON), 1377.
Tolidines, *di*nitro-, isomerism of (LE FÈVRE and TURNER), 963.
Toluene, 3-bromo-5-iodo-, and 3-chloro-5-iodo- (MCALISTER and KENNER), 1914.
halogeno- and nitro-derivatives, catalytic oxidation of, by means of air (MAXTED and DUNSBY), 1439.
Toluenes, substituted, determination of isomeric nitro-derivatives of (FLÜRSCHEIM and HOLMES), 448.
6-*p*-Tolueneazo-2:4-bis*tri*chloromethyl-1:3-benzdioxin (CHATTAWAY and CALVET), 1092.
p-Tolueneseleninic acid, 2-nitro- (CHALLENGER and PETERS), 1369.
Toluenesulphonic acid, esters, use of, in synthesis of malonic esters (PEACOCK and THA), 2303.
Toluene-*p*-sulphonic acid, ammonium salt and β-carbethoxyethyl, β-chloroethyl, β-cyanoethyl, and γ-imino-γ-ethoxypropyl esters of, and their properties and reactions (CLEMO and WATSON), 723.
ethyl ester (FREIMAN and SUGDEN), 267.
β-phenoxyethyl ester (PEACOCK and THA), 2305.

Toluenesulphonic acids, iodo-, and their derivatives (BARBER and SMILES), 1144.
p-**Toluenesulphonyl** chloride, parachor for (FREIMAN and SUGDEN), 267.
m-**Toluic acid**, ω-chloro-, ethyl ester (TITLEY), 2582.
p-**Toluic acid**, ω-*mono*- and ωω'-*di*-bromo-, ethyl esters (TITLEY), 2581.
6-nitro-5-hydroxy- (CHATTAWAY and CALVET), 1094.
Toluic acids, *d*-β-octyl esters (RULE, HAY, NUMBERS, and PATERSON), 183.
p-**Toluidine**, compound of benzoylacetonitrile and, and its derivatives (KRISHNAMURTI), 416.
1-**Toluidino-1-cyano***cyclo***hexanes** (BETTS and PLANT), 2071.
1-**Toluidino***cyclo***hexane-1-carboxylic acids**, and their amides (BETTS and PLANT), 2071.
m-**Toluoyl** chloride, ω-chloro- (TITLEY), 2582.
p-**Toluoyl** bromide, ω-bromo- (TITLEY), 2581.
α-*m*-**Tolylallyl alcohol**, and its *p*-nitrobenzoate (BURTON), 1656.
α-*p*-**Tolylallyl alcohol**, and its derivatives (BURTON and INGOLD), 915.
s-o-**Tolyl-***n*-**heptylthiocarbamide**, and its hexabromide, and 5-bromo- (HUNTER and STYLES), 3026.
o-**Tolylmethylthiocarbamides**, and their bromides (HUNTER and STYLES), 3024.
s-o-**Tolyl-***n*-**propylthiocarbamide**, and 5-bromo- (HUNTER and STYLES), 3026.
p-**Tolylstibinic acid** (GODDARD and YARSLEY), 721.
Tolylthymylacetic acid, and its derivatives (BELL and HENRY), 2225.
Transmutation, experiments on (FRIEND), 1321.
O-**Triacetylbrazilone** (PERKIN, RÂY, and ROBINSON), 1513.
Triacetyldesmethylpyropseudaconitine (SHARP), 3098.
3:4:6-Triacetyl β-ethylglucoside (HICKINBOTTOM), 3145.
Triacetylethylpseudaconine (SHARP), 3102.
3:4:6-Triacetyl glucose 1:2-anhydride, and its glucosides (HICKINBOTTOM), 3140.
3:4:6-Triacetyl-2-methyl β-ethylglucoside (HICKINBOTTOM), 3145.
Triacetylmethylpseudaconine (SHARP), 3102.
Triazoles (BRADY and REVNOLDS), 193.
O-**Tribenzoylbrazilone** (PERKIN, RÂY, and ROBINSON), 1513.
9:9:10-Tribenzyl-9:10-dihydroanthranol (BARNETT and COOK), 571.
Tribenzylsilicyl oxide, preparation of (STEELE and KIPPING), 1431.
Tribenzylstannic iodide (KIPPING), 2367.
Tricarvacrylmethane, and its acetyl derivative (BELL and HENRY), 2223.
Triethylenediaminenickel chloride, attempted resolution of (BUCKNALL and WARDLAW), 2739.
Triethyltelluronium iodide (GILBERT and LOWRY), 3184.
3:4:5-Trimethoxyacetophenone, ω-hydroxy-, and its benzoyl derivative (BRADLEY and ROBINSON), 1550.
ω:**3:5-Trimethoxyacetophenone**, and its semicarbazone (ROBERTSON, ROBINSON, and SUGIURA), 1535.
ω:**3:5-Trimethoxyacetophenone**, 4-hydroxy- (BRADLEY and ROBINSON), 1567.
dl-**3:4:6-Trimethoxyaporphine** (GULLAND and HAWORTH), 2086.
3:4:5-Trimethoxybenzoylacetoxyacetic acid, ethyl ester (BRADLEY and ROBINSON), 1550.
2':4':6'-Trimethoxybenzoyl-*o*-benzoic acid (LUND), 1574.
3:4:5-Trimethoxybenzoylbenzoyloxyacetic acid, ethyl ester (BRADLEY and ROBINSON), 1549.
6:3':4'-Trimethoxy-1-benzoyl-3:4-dihydro*iso*quinoline, 2'-nitro- (GULLAND and HAWORTH), 2086.
6:3':-4'-Trimethoxy-1-benzyl-3:4-dihydro*iso*quinoline, 2'-nitro-, and its salts (GULLAND and HAWORTH), 2085.
6:3':4'-Trimethoxy-1-benzylidene-2-methyltetrahydro*iso*quinoline, 2'-nitro- (GULLAND and HAWORTH), 2085.
6:3':4'-Trimethoxy-1-benzyl-2-methyltetrahydro*iso*quinoline, 2'-amino-, and its dihydrochloride (GULLAND and HAWORTH), 2086.
3:4:8-Trimethoxy-5-cyanophenanthrene (GULLAND and VIRDEN), 927.
3:4:8-Trimethoxy-5-ethylphenanthrene (GULLAND and VIRDEN), 933.
3:4:8-Trimethoxy-5-ethylphenanthrene-9-carboxylic acid (GULLAND and VIRDEN), 933.
5:7:4'-Trimethoxy*iso*flavone, and its 2-carboxylic acid (BAKER and ROBINSON), 3117.
3:3':5'-Trimethoxyflavylium chloride, 7:5-*di*hydroxy-, and its 5-benzoyl derivative (ROBERTSON, ROBINSON, and SUGIURA), 1536.
5:7:4'-*tri*hydroxy-, and its 5-benzoyl derivative (BRADLEY and ROBINSON), 1567.

3′:4′:5′-Trimethoxyflavylium chloride, 3:5:7-*tri*hydroxy- (BRADLEY and ROBINSON), 1551.
3:4:8-Trimethoxyphenanthrene-5-carboxylic acid, derivatives of (GULLAND and VIRDEN), 926.
3:4:5-Trimethoxyphenylglyoxal diphenylhydrazone (BRADLEY and ROBINSON), 1551.
2′:4′:6′-Trimethoxyphenylphthalide (LUND), 1573.
5:7:4′-Trimethoxy-2-styryl*iso*flavone (BAKER and ROBINSON), 3116.
5:7:4′-Trimethoxy-2-styryl-6-methyl*iso*flavone (BAKER and ROBINSON), 3117.
Tri-4-methoxytriphenylselenonium salts (MORGAN and BURSTALL), 3265.
Trimethylalkylammonium hydroxides, decomposition of (INGOLD and VASS), 3126.
Trimethylamine, velocity of reaction of, with *m*- and *p*-nitrobenzyl chlorides (NORRISH and SMITH), 130.
Triethylamine-6β′β″-triarsinic acid, and its salts (GOUGH and KING), 2434.
1:3:4-Trimethyl-5:6-benz-4-carbolinium methyl sulphate (KERMACK and SLATER), 796.
O-Trimethylbrazilane. See Dihydrodeoxytrimethylbrazilone.
Trimethylbrazilone, and its reduction product (PERKIN, RÂY, and ROBINSON), 1510.
1:1′:6-(or 1:1′:6′)-Trimethyl-ψ-cyanine iodide (HAMER), 211.
Trimethyldihydrobrazilone, and its derivatives (PERKIN, RÂY, and ROBINSON), 1511.
Trimethylene glycol di-*p*-toluenesulphonate (GOUGH and KING), 2446.
Trimethyl γ-fructose, and its osazone (HAWORTH and LEARNER), 623.
ααβ-Trimethylglutaric acid, α′-hydroxy-, lactone (BARDHAN), 2620.
Trimethyl inulin (HAWORTH and LEARNER), 622.
ααβ-Trimethyl-lævulic acid, and its derivatives (BARDHAN), 2613.
2:3:4-Trimethyl-lyxonic acid, phenylhydrazide (HIRST and SMITH), 3153.
Trimethyl-δ-lyxonolactone (HIRST and SMITH), 3152.
Trimethyl lyxose (HIRST and SMITH), 3151.
Trimethyl methyl-lyxoside (HIRST and SMITH), 3150.
ααβ-Trimethyl-Aβ-pentenoic acid, and its derivatives (BARDHAN), 2615.
NN′-Trimethyl-2-phenylnaphthalene-1:3-diamine, and its acetyl derivative (GIBSON, KENTISH, and SIMONSEN), 2141.
2:2:6-Trimethylpiperidine, and its salts (GOUGH and KING), 2444.
γ-2:2:6-Trimethylpiperidinopropylarsinic acid, and γ-4-hydroxy- (GOUGH and KING), 2444.
Trimethylplatinum acetylacetone (MENZIES), 565.
Trimethylsuccinic acid, preparation of (BARDHAN), 2611.
α- and β-2:3:7-Trimethyl-1:2:3:4-tetrahydroquinoxalines, resolution of, and their salts and derivatives (GIBSON, NUTLAND, and SIMONSEN), 108.
d- and *l*-β-2:3:7-Trimethyl-1:2:3:4-tetrahydroquinoxalino-1-methylenecamphor (GIBSON, NUTLAND, and SIMONSEN), 114.
2:2′:3-Trimethylthiocarbocyanine iodide (HAMER), 3162.
Trimethyltriphenylselenonium oxide and salts, *tri*bromo*tri*hydroxy- and *tri*hydroxy- (MORGAN and BURSTALL), 3266.
ααβ-Trimethyl-*n*-valeric acid, β-hydroxy-, ethyl ester (BARDHAN), 2615.
Trimethyl γ-xylonolactone, and its phenylhydrazide (HAWORTH and PORTER), 617.
Triolein, heating of, with sulphur (KNIGHT and STAMBERGER), 2791.
Trional, parachor for (FREIMAN and SUGDEN), 265.
Triphenoxselenylium dibisulphate, sulphuric acid dihydrate (DREW), 523.
Triphenylbenzylstannane (KIPPING), 2368.
Triphenyl-*n*-butylstannane (KIPPING), 2370.
Triphenylcarbinol-2:2′-dicarboxylic acid, lactonic acid of (COOK), 64.
Triphenylmethyl, photodecomposition of (BOWDEN and JONES), 1149.
Triphenylmethylphosphorous acid, di-*p*-tolyl ester (BOYD and HARDY), 636.
Triphenylselenonium oxide and salts, *tri*bromo*tri*hydroxy-, *tri*hydroxy- and *tri*-2:4-*di*hydroxy- (MORGAN and BURSTALL), 3264.
Triphenyl-*o*-tolylstannane (KIPPING), 2369.
Trisethylenethiocarbamido-mercuric nitrate (MORGAN and BURSTALL), 154.
Trithymylmethane, and its acetyl derivative (BELL and HENRY), 2223.
Tri-*m*-tolylstannic chloride (KIPPING), 2369.
Tri-*p*-tolylstibine, *tri*-*m*-amino-, *tri*-*m*-iodo- and *tri*-*m*-nitro-, and its oxide and *di*nitrate (GODDARD and YARSLEY), 722.

Tritolyltolylstannanes (KIPPING), 2369.
Truxinic acid, synthesis of (VOGEL), 1021.
Trypanocidal action and chemical constitution (GOUGH and KING), 2426.
Tungsten, surface oxidation of (BANNISTER), 3163.
Turpentine, Indian, constituents of, from *Pinus longifolia* (PILLAY and SIMONSEN), 359.

U.

Unsaturated compounds, catalytic hydrogenation (LEBEDEV and YAKUBCHIK), 823, 2190.
homocyclic, chemistry of polycyclic compounds in relation to isomeric (GOSS), 1306.
Urocanic acid, ethyl ester, picrate (HUBBALL and PYMAN), 26.

V.

Valency (LOWRY, GOLDSTEIN, and GILBERT), 307; (BERRY and LOWRY), 1748; (GILBERT and LOWRY), 1997, 2658, 3179.
hypothesis of deflexion of (INGOLD and THORPE), 1318.
Vapour pressure, influence of glass on (RINSE), 1442.
Velocity of reaction, activity theory of (WYNNE-JONES), 1230.
equation for (SOPER), 1233.
bimolecular, coefficient for (NORRISH and SMITH), 129.
Veratroylmethylpseudaconine, and its acetyl derivatives and salts (SHARP), 4100.
β-Veratrylbutyric acid, and 6-bromo- (KOEPFLI and PERKIN), 2996.
β-Veratrylcrotonic acid, and its ethyl ester (KOEPFLI and PERKIN), 2995.

W.

Walden inversion (RØRDAM), 2447.

Xanthone, 2:4:5:7-*tetra*nitro-, and 2:7-*di*bromo-4:6-*di*nitro- (LE FÈVRE), 3251.
Xanthones, halogenonitro- and nitro-, action of piperidine with (LE FÈVRE), 3249.
***o*-Xylenes**, *di-* and *tri*-chloro-, *di*chloroamino-, and *di*chloronitro- (HINKEL, AYLING, and BEVAN), 1874.
***p*-Xylene**, ω-bromo- and ω-chloro-, nitration of (INGOLD and ROTHSTEIN), 1278.
ω(1)-bromo-3-nitro- (INGOLD and ROTHSTEIN), 1220.
***o*-Xylenols**, amino-, chloro-, and chloroamino-, and their derivatives (HINKEL, AYLING, and BEVAN), 2529.
***o*-4-Xylidines**, *di*chloro- (HINKEL, AYLING, and BEVAN), 1878.
***m*-4-Xylidine**, compound of benzoylacetonitrile and, and its benzoyl derivative (KRISHNAMURTI), 416.
γ-Xylose, derivatives of (HAWORTH and PORTER), 611.
***p*-Xylyl bromide**, 3-nitro-. See *p*-Xylene, ω(1)-bromo-3-nitro-.
***p*-Xylyl-ω-trimethylammonium picrate**, 3-nitro- (INGOLD and ROTHSTEIN), 1220.

Z.

Zinc hyponitrite (NEOGI and NANDI), 1452.
sulphate, equilibria of, with sodium sulphate and water (CAVEN and JOHNSTON), 2506.

FORMULA INDEX.

THE following index of organic compounds of known empirical formula is arranged according to Richter's system (see *Lexikon der Kohlenstoff-Verbindungen*).

The elements are given in the order C, H, O, N, Cl, Br, I, F, S, P, and the remainder alphabetically.

The compounds are arranged—

Firstly, in groups according to the number of carbon atoms (thus C_1 group, C_2 group, etc.).

Secondly, according to the number of other elements besides carbon contained in the molecule (thus 5 IV indicates that the molecule contains five carbon atoms and four other elements).

Thirdly, according to the nature of the elements present in the molecule (given in the above order).

Fourthly, according to the number of atoms of each single element (except carbon) present in the molecule.

Salts are placed with the compounds from which they are derived. The chlorides, bromides, iodides, and cyanides of quaternary ammonium bases, however, are registered as group-substances.

C_1 Group.

CO Carbon monoxide, decomposition of, in the corona discharge (OTT), 1378; inflammation of mixtures of air and (MAXWELL and WHEELER), 15; effect of catalysts on flame speed, infra-red emission, and ionisation during combustion of oxygen and (GARNER and JOHNSON), 280.

CS_2 Carbon disulphide, ignition of (WHITE), 751.

1 II

CHN Hydrocyanic acid, and its alleged isomerides (COATES, HINKEL, and ANGEL), 540; cuprous salt, action of methyl iodide on (HARTLEY), 780.

CH_2N_2 Diazomethane, acylation of (BRADLEY and SCHWARZENBACH), 2904; action of benzoyl chloride with (BRADLEY and ROBINSON), 1310.

CH_2S_3 Trithiocarbonic acid (MILLS and ROBINSON), 2330.

CH_2S_4 Tetrathiocarbonic acid, and its ammonium salt (MILLS and ROBINSON), 2330.

CH_3I Methyl iodide, action of cuprous cyanide on (HARTLEY), 780.

CH_5N Methylamine, action of nitrous acid on (TAYLOR), 1100.

CH_5N_3 Guanidine, and its carbonate, hydrolysis of (BELL), 2074.

1 III

CH_6ON_4 Carbohydrazide, reactions of (MUNRO and WILSON), 1257.

C_2 Group.

C_2H_2 Acetylene, action of sulphur on, up to 650° (PEEL and ROBINSON), 2068.

2 II

$C_2H_2O_2$ Glyoxal, photochemical decomposition of (NORRISH and GRIFFITHS), 2829.

$C_2H_2O_4$ Oxalic acid, complex molybdenum salts of (SPITTLE and WARDLAW), 2742.

$C_2H_4O_2$ Acetic acid, inert salt effects in catalysis by, and its salts (DAWSON and KEY), 1248; lead subsalt, and its reactions with phenols (GIBSON and MATTHEWS), 596; magnesium salt, constitution of solutions of (GOODE, BAYLISS, and RIVETT), 1950.

$C_2H_8N_2$ Ethylenediamine, equilibria of phenols with (PUSHIN and SLADOVICH), 337.

2 III

C_2HOCl_3 Chloral, action of, on phenylhydrazines (CHATTAWAY and DALDY), 2756; condensations of, with anisic acid, *p*-nitroanisole, and 2:6-dichloroquinol (CHATTAWAY and CALVET), 2913; condensation of, with substituted phenols (CHATTAWAY and CALVET), 1088.

$C_2H_2OCl_2$ Dichloroacetaldehyde, condensation of phenols with (CHATTAWAY and MORRIS), 3241.

C_2H_3OCl Acetyl chloride, speed of bromination of (WATSON), 1137.

C_2H_3OBr Acetyl bromide, speed of bromination of (WATSON), 1137.

C_2H_3Ng Mercuric methyl cyanide (COATES, HINKEL, and ANGEL), 542.

$C_2H_4O_4N_2$ β-Hydroxyethylnitrolic acid (EARL, ELLESWORTH, JONES, and KENNER), 2701.

$C_2H_7O_4As$ β-Hydroxyethylarsinic acid, and its calcium salt (GOUGH and KING), 2432.

2 IV

$C_2H_2O_2ClBr$ Chlorobromoacetic acid, racemic, resolution of (BACKER and MOOK), 2125.

$C_2H_6O_2ClAs$ β-Chloroethylarsinic acid (GOUGH and KING), 2434.

C_3 Group.

$C_3H_4O_4$ Malonic acid, condensation of *cyclo*hexanealdehyde and (SIRCAR), 54.

C_3H_6O Acetone, water catenary in iodination of (DAWSON and KEY), 543.

C_3H_9N Trimethylamine, velocity of reaction of, with nitrobenzyl chlorides (NORRISH and SMITH), 130.

$C_3H_{12}N_2$ Triaminopropane, complex palladium and platinum salts of (MANN), 890.

3 III

C_3H_5OCl Chloroacetophenone, formation of, from benzoyl chloride (BRADLEY and SCHWARZENBACH), 2904.

$C_3H_5O_2N$ *d*-Glutamic acid, action of aniline on (GRAY), 1264.

$C_3H_6N_2S$ Ethylenethiocarbamide, complex metallic salts with (MORGAN and BARTLETT), 143.

$C_3H_6Cl_2As$ γ-Chloropropyldichloroarsine (GOUGH and KING), 2439.

$C_3H_7O_3N$ β-Nitropropanol, sodium salt (EARL, ELLESWORTH, JONES, and KENNER), 2702.

$C_3H_9O_3B$ Methyl borate, preparation and constants of (ETRIDGE and SUGDEN), 991.

$C_3H_9O_4As$ γ-Hydroxypropylarsinic acid, and its calcium salt (GOUGH and KING), 2439.

3 IV

$C_3H_5ON_4S$ 3-Amino-2:4-diketotetrahydrothiazole 2-hydrazone (STEPHEN and WILSON), 1418.

$C_3H_7O_4SLi$ Acetone lithium hydrogen sulphate (FRIEND and POUNDER), 2248.

$C_3H_8O_3ClAs$ γ-Chloropropylarsinic acid, and its salts (GOUGH and KING), 2440.

$C_3H_{10}O_3NAs$ γ-Aminopropylarsinic acid (GOUGH and KING), 2440.

$C_3H_{11}N_3Cl_2Pt$ Chlorotriaminopropaneplatinous chloride (MANN), 896.

$C_3H_{12}N_3Cl_3Pt$ Dichloro(triaminopropane-hydrochloride) platinum (MANN), 895.
$C_3H_{12}N_3Cl_3Pd$ Dichloro(triaminopropane-γ-hydrochloride) palladium (MANN), 897.

3 V

$C_3H_2O_2N_3S_3Mo$ Dihydrogen molybdenum dioxytrithiocyanate, and its salts (JAMES and WARDLAW), 2732.

C_4 Group.

$C_4H_2O_6$ Tartaric acid, triethylenediaminenickel salt (BUCKNALL and WARDLAW), 2741.
C_4H_4S Thiophen, production of, from acetylene and carbon disulphide (BRISCOE, PEEL, and ROBINSON), 2857.
C_4H_4Se Selenophen (BRISCOE and PEEL), 1741; (BRISCOE, PEEL, and ROBINSON), 2628.
$C_4H_6O_3$ Acetic anhydride, physical properties of (JONES), 1193; miscibility of (JONES and BETTS), 1177; action of bromine on (WATSON and ROBERTS), 2779.
$C_4H_6O_4$ Acetyl peroxide, decomposition of (WALKER), 2040.
$C_4H_6O_5$ Malic acid, optical activity of, in presence of sodium molybdate (PATTERSON and BUCHANAN), 3006.
$C_4H_6Br_2$ Butadiene dibromides, isomeric (FARMER, LAWRENCE, and THORPE), 729.
$C_4H_8O_2$ Ethyl acetate, catalysis by hydrochloric acid of hydrolysis of (DAWSON and LOWSON), 2146.
$C_4H_{10}O$ Ethyl ether, action of disilicon hexachloride on (KIPPING and THOMPSON), 1989.
$C_4H_{12}N_2$ β-Methyltrimethylenediamine, complex platinum salts of (MANN), 1261.
C_4Cl_4Se Tetrachloroselenophen (BRISCOE and PEEL), 1747.
C_4Br_4Se Tetrabromoselenophen (BRISCOE and PEEL), 1746.

4 III

$C_4H_4ON_2$ Glyoxaline-4(5)-formaldehyde, and its salts (HUBBALL and PYMAN), 21.
$C_4H_4Cl_4S$ αββ′-Tetrachlorodiethyl sulphide (MUMFORD and PHILLIPS), 160.
$C_4H_4Cl_6S$ ααββββ′-Hexachlorodiethyl sulphide (MUMFORD and PHILLIPS), 160.
$C_4H_5ON_3$ Glyoxaline-4(5)-formaldoxime (HUBBALL and PYMAN), 25.
$C_4H_5Cl_3S$ αββ′-Trichlorodiethyl sulphide (MUMFORD and PHILLIPS), 160.
$C_4H_6O_2S_2$ 1:3-Dithiolan-2-carboxylic acid (CHIVERS and SMILES), 700.
C_4H_7ON Acetonecyanohydrin, preparation of (WELCH and CLEMO), 2629.
$C_4H_8O_2S_2$ Dithian monoxide, and its salts (BELL and BENNETT), 90.
$C_4H_8O_2S_2$ Dithian dioxides, and their salts (BELL and BENNETT), 88.
$C_4H_8Cl_2S$ ββ′-Dichlorodiethyl sulphide, chlorination of (MUMFORD and PHILLIPS), 155.
$C_4H_{10}O_2Cu$ Cupric ethoxide (DOAK and PACKER), 2768.
$C_4H_{10}O_2Te$ Diethyltellurone (GILBERT and LOWRY), 3182.
$C_4H_{10}Cl_2Te$ Diethyltelluronium dichlorides (GILBERT and LOWRY), 3183.
$C_4H_{10}Br_2Te$ Diethyltelluronium dibromides (GILBERT and LOWRY), 3183.
$C_4H_{10}I_2Te$ Diethyltelluronium di-iodides (GILBERT and LOWRY), 3185.
$C_4H_{10}I_4Te$ α-Diethyltelluronium α-tetraiodide (GILBERT and LOWRY), 3181.

4 IV

$C_4H_6O_2N_4S$ 2:4-Diketotetrahydrothiazole 2-semicarbazone (STEPHEN and WILSON), 1421.

$C_4H_6O_2Br_2S_2$ 1:3-Dithiolan-2-carboxylic acid dibromide (CHIVERS and SMILES), 700.

$C_4H_6O_2I_2S_2$ 1:3-Dithiolan-2-carboxylic acid di-iodide (CHIVERS and SMILES), 700.

$C_4H_8ON_4S$ 3-Amino-2:4-diketo-5-methyltetrahydrothiazole 2-hydrazone (STEPHEN and WILSON), 1418.

$C_4H_{12}O_3NAs$ β-Dimethylaminoethylarsinic acid, and its hydrochloride (GOUGH and KING), 2435.

4 V

$C_5H_{12}ONCl_4Mo$ Tetramethylammonium molybdenyl tetrachloride (JAMES and WARDLAW), 2738.

C_5 Group.

C_5H_8 Isoprene, hydrogenation of (LEBEDEV and YAKUBCHIK), 828.

5 II

C_5H_5N Pyridine, nuclear fission of (SHAW and WILKIE), 1377; inhibition of esterification by (BAILEY), 1204; additive compound of phosphoryl chloride and (BOYD and LADHAMS), 218.

$C_5H_8O_2$ β-Methylbutyrolactone, and its silver salt (SIRCAR), 901.

$C_5H_{10}O$ Dimethyltrimethylene oxides (BENNETT and PHILIP), 1938.

$C_5H_{10}O_5$ Lyxose, structure of (HIRST and SMITH), 3147.

$C_5H_{10}Te$ *cyclo*Telluropentane (MORGAN and BURGESS), 327.

$C_5H_{11}N$ Piperidine, interaction of, with derivatives of xanthone and diphenylene oxide (LE FÈVRE), 3249.

$C_5H_{12}O$ Methyl *sec.*-butyl ether (BENNETT and PHILIP), 1931.

5 III

$C_5H_8ON_2$ Methylglyoxalineformaldehydes, salts of (HUBBALL and PYMAN), 27, 28.

$C_5H_6O_2N_2$ 5-Carboxy-1-methylglyoxaline, picrate of (HUBBALL and PYMAN), 28.

$C_5H_7ON_5$ Glyoxaline-4(5)-formaldehyde semicarbazone (HUBBALL and PYMAN), 25.

$C_5H_7O_5Mo$ Molybdenyl acetylacetone (MORGAN and CASTELL), 3255.

$C_5H_8ON_2$ 1-Methyl-5-hydroxymethylglyoxaline, picrate of (HUBBALL and PYMAN), 28.

$C_5H_8O_2S_2$ 1:3-Dithian-2-carboxylic acid (CHIVERS and SMILES), 701.

$C_5H_{10}O_2Te$ *cyclo*Telluripentane 1:1-dioxide (MORGAN and BURGESS), 327.

$C_5H_{10}Cl_2Te$ *cyclo*Telluripentane 1:1-dichloride (MORGAN and BURGESS), 325.

$C_5H_{10}Br_2Te$ *cyclo*Telluripentane 1:1-dibromide (MORGAN and BURGESS), 326.

$C_5H_{10}I_2Te$ *cyclo*Telluripentane 1:1-di-iodide (MORGAN and BURGESS), 328.

$C_5H_{13}ON$ γ-Amino-β-hydroxy-β-methylbutane, and its salts (READ and REID), 1491.

5 IV

$C_5H_6O_2S_2I_2$ Di-iodo-1:3-dithian-2-carboxylic acid (CHIVERS and SMILES), 701.

$C_5H_{10}ONCl$ α-Chloro-γ-imino-γ-ethoxypropane, hydrochloride of (CLEMO and WATSON), 729.

$C_5H_{10}ON_4S$ 3-Amino-2:4-diketo-5-ethyltetrahydrothiazole 2-hydrazone (STEPHEN and WILSON), 1419.

$C_5H_{14}O_3NAs$ γ-Dimethylaminopropylarsinic acid, and its hydrochloride (GOUGH and KING), 2441.

$C_5H_{15}O_6NAs_2$ Methyldiethylamine-ββ′-diarsinic acid (GOUGH and KING), 2435.

5 V

$C_5H_2ON_6S_4Mo$ Dihydrogen molybdenyl pentathiocyanate, salts of (JAMES and REDLAW), 2736.

$C_5H_{15}O_3NClAs$ β-Dimethylaminoethylarsinic acid methochloride (GOUGH and KING), 2435.

C_6 Group.

C_6H_6 Benzene, velocity measurements in relation to substitution in (BRADFIELD and JONES), 3073.

C_6H_{14} *n*-Hexane, oxidation of (BRUNNER and RIDEAL), 1162, 2824.

6 II

C_6H_7N Aniline, action of *d*-glutamic acid with (GRAY), 1264.

$C_6H_8O_6$ Propane-*aaγ*-tricarboxylic acid (LENNON and PERKIN), 1524.

$C_6H_{10}O$ Mesityl oxide, catalysis in iodination of (DAWSON and KEY), 2154.

$C_6H_{10}O_2$ β-Ethylbutyrolactone, and its silver salt (SIRCAR), 901.

β-Methylvalerolactone, and its silver salt (SIRCAR), 902.

$C_6H_{10}O_3$ Ethyl acetoacetate, condensations with (FRANKLIN and SHORT), 591; condensation of ketones with (JUPP, KON, and LOCKTON), 1638; reactions of, with distyryl ketones (HEILBRON and HILL), 2863.

$C_6H_{12}O_3$ *n*-Butoxyacetic acid (RULE, HAY, and PAUL), 1356.

$C_6H_{12}O_6$ Galactose, mutarotation of (SMITH and LOWRY), 666

6 III

$C_6H_2O_{10}N_6$ Pentanitroaniline (FLÜRSCHEIM and HOLMES), 3041.

$C_6H_3O_3Cl_3$ Parachlorals (CHATTAWAY and KELLETT), 2711.

$C_6H_3N_6Fe$ Hydroferricyanic acid, potassium salt, solubility of, in water (FRIEND and SMIRLES), 2242.

$C_6H_4O_2Cl_2$ 2:6-Dichloroquinol, condensation of chloral with (CHATTAWAY and CALVET), 2913.

$C_6H_4O_8N_4$ 2:4:6-Trinitro-5-aminoresorcinol (FLÜRSCHEIM and HOLMES), 3044.

C_6H_4ClF *p*-Fluorochlorobenzene, nitration of (INGOLD and VASS), 2265.

C_6H_5BrMg Magnesium phenyl bromide, action of, on methyl *o*-cyanobenzoate (BOYD and LADHAMS), 2089.

$C_6H_6O_6N_6$ 2:4:6-Trinitro-1:3:5-triaminobenzene (FLÜRSCHEIM and HOLMES), 3045.

$C_6H_8ON_2$ 1:4-Dimethylglyoxaline-5-formaldehyde, and its picrate (HUBBALL and PYMAN), 29.

$C_6H_8O_2N_2$ 1:4-Dimethylglyoxaline-5-carboxylic acid, and its picrate (HUBBALL and PYMAN), 30.

Methyl 1-methylglyoxalinecarboxylates (HUBBALL and PYMAN), 31.

$C_6H_8O_6Tl_6$ Thallium sorbitol (MENZIES and KIESER), 190.

$C_6H_9O_5Tl_3$ Trithallium methylarabinoside (MENZIES and KIESER), 188.

$C_6H_{11}ON$ Methylpentenoic amides (GOLDBERG and LINSTEAD), 2355.

$C_6H_{11}O_7Tl$ Thallous gluconate (MENZIES and KIESER), 189.

$C_6H_{14}NCl$ β-Chloroethyldiethylamine, and its salts (GOUGH and KING), 2436.

$C_6H_{15}O_3B$ Ethyl borate, preparation and constants of (ETRIDGE and SUGDEN), 992.

$C_6H_{15}ITe$ Triethyltelluronium iodide (GILBERT and LOWRY), 3184.

6 IV

$C_6H_3O_7N_3F$ 3-Fluoro-2:4:6-trinitrophenol (HODGSON and NIXON), 1882.

$C_6H_3O_5N_2F$ Fluorodinitrophenols, and their salts (HODGSON and NIXON), 1881.

$C_6H_4O_3NF$ Fluoronitrophenols, and their salts (HODGSON and NIXON), 1880.

$C_6H_5ONCl_2$ 2:4-Dichloro-6-aminophenol, hydrochloride of (HUNTER and BARNES), 2056.

$C_6H_5ONI_2$ 2:4-Di-iodo-6-aminophenol, hydrochloride of (HUNTER and BARNES), 2058.

$C_6H_5O_2ClS$ Chlorobenzene-*p*-sulphinic acid, and its ammonium salt (DAVIES and WOOD), 1126.

$C_6H_5O_6ClS_2$ Chlorobenzene-2:4-disulphonic acid, and its potassium salt (DAVIES and WOOD), 1124.

$C_6H_5O_9ClS_3$ Chlorobenzene-2:4:6-trisulphonic acid, and its potassium salt (DAVIES and WOOD), 1125.

C_6H_5NClF 3-Fluoro-4-chloroaniline (INGOLD and VASS), 422.

C_6H_5NBrI 2-Bromo-4-iodoaniline (BRADFIELD, ORTON, and ROBERTS), 783.

C_6H_6ONCl Chloroaminophenols, and their hydrochlorides (HODGSON and KERSHAW), 2704.

C_6H_6ONBr Bromoaminophenols, and their hydrochlorides (HODGSON and KERSHAW), 2704.

C_6H_6ONI *p*-Iodo-*o*-aminophenol, hydrochloride of (HUNTER and BARNES), 2057.

Iodoaminophenols, and their hydrochlorides (HODGSON and KERSHAW), 2704.

$C_6H_6O_2NAs$ 5-Amino-2-hydroxyphenylarsenoxide, salts of (NEWBERY and PHILLIPS), 2379.

$C_6H_6O_2N_3Cl$ Chloronitrophenylhydrazines (PLANT and ROSSER), 2461.

$C_6H_6O_6NAs$ 4-Nitro-3-hydroxyphenylarsinic acid, and its salts (BALABAN), 810.

$C_6H_7O_4NS$ 6-Amino-2:4-bistrichloromethyl-1:3-benzdioxin (CHATTAWAY and COULSON), 1090.

$C_6H_7O_6N_2As$ 2-Nitro-4-amino-3-hydroxyphenylarsinic acid, and its magnesium salt (BALABAN), 811.

5-Nitro-4-amino-3-hydroxyphenylarsinic acid (BALABAN), 3071.

$C_6H_{12}NCl_3As$ γ-*n*-Propylaminopropyldichloroarsine hydrochloride (GOUGH and KING), 2442.

$C_6H_{16}O_3NAs$ γ-*n*-Propylaminopropylarsinic acid, and its hydrochloride (GOUGH and KING), 2441.

$C_6H_{18}O_9NAs_3$ Triethylamine-$\beta\beta'\beta''$-triarsinic acid, and its salts (GOUGH and KING), 2434.

$C_6H_{22}N_6Br_2Pt$ Bis(triaminopropane)platinous dibromide (MANN), 897.

$C_6H_{22}N_6I_2Pt$ Bis(triaminopropane)platinous di-iodide (MANN), 897.

$C_6H_{24}N_6Cl_2Ni$ Triethylenediaminenickel chloride (BUCKNALL and WARDLAW), 2741.

6 V

$C_6H_2O_4N_2BrI$ 1-Bromo-3-iodo-4:6-dinitrobenzene (MAYES and TURNER), 693.

$C_6H_3O_2NClF$ Fluorochloronitrobenzenes (INGOLD and VASS), 422.

$C_6H_3O_2NBrI$ 1-Bromo-3-iodo-6-nitrobenzene (MAYES and TURNER), 693.

$C_6H_4O_2N_2ClI$ Chloroiodo-6-nitroanilines (BRADFIELD, ORTON, and ROBERTS), 784.

$C_6H_4O_2N_2BrI$ Bromoiodo-6-nitroaniiines (BRADFIELD, ORTON, and ROBERTS), 784.

$C_6H_4O_5NClS$ 1-Chloro-2-nitrobenzene-4-sulphonic acid, and its potassium salt (DAVIES and WOOD), 1125.

$C_6H_4NClBrI$ Chlorobromoiodoanilines (BRADFIELD, ORTON, and ROBERTS), 783.

$C_6H_5ONClBr$ Chlorobromoaminophenols, and their hydrochlorides (HUNTER and BARNES), 2060.

C_6H_5ONClI Chloro-6-iodoaminophenols, and their hydrochlorides (HUNTER and BARNES), 2061, 2065.

C_6H_5ONBrI Bromoiodoaminophenols, and their hydrochlorides (HUNTER and BARNES), 2062.

$C_6H_5O_2N_2I_2As$ 3-Nitro-4-hydroxy-5-aminophenyldi-iodoarsine, hydriodide of (NEWBERY and PHILLIPS), 2381.

$C_6H_5O_5NClAs$ 3-Chloronitrophenylarsinic acids, and their salts (BALABAN), 810.

$C_6H_6ONCl_2As$ 5-Amino-2-hydroxyphenyldichloroarsine, hydrochloride of (NEWBERY and PHILLIPS), 2379.

$C_6H_6ONI_2As$ Aminohydroxyphenyldi-iodoarsines, hydriodides of (NEWBERY and PHILLIPS), 2378.

$C_6H_7ON_2Cl_2As$ 3:5-Diamino-4-hydroxyphenyldichloroarsine, hydrochloride of (NEWBERY and PHILLIPS), 2377.

$C_6H_7O_2N_2I_2As$ 3:5-Diamino-4-hydroxyphenyldi-iodoarsine, hydriodide of (NEWBERY and PHILLIPS), 2378.

$C_6H_7O_4N_2ClS_2$ Chlorobenzene-2:4-disulphonamide (DAVIES and WOOD), 1125.

$C_6H_{12}ON_4S_2As_2$ Ethylenethiocarbamido-argentous oxide, and its salts (MORGAN and BURSTALL), 151.

$C_6H_{12}ON_4S_2Au_2$ Ethylenethiocarbamido-aurous oxide, and its salts (MORGAN and BURSTALL), 153.

$C_6H_{12}ON_4S_2Cu_2$ Ethylenethiocarbamido-cuprous oxide and its salts (MORGAN and BURSTALL), 149.

$C_6H_{17}O_2NClAs$ γ-Dimethylaminopropylarsinic acid methochloride (GOUGH and KING), 2441.

$C_6H_{18}O_6NClAs_2$ Dimethyldiethylammonium chloride ββ′-diarsinic acid (GOUGH and KING), 2435.

$C_6H_{20}ON_2Cl_5Mo$ Ditrimethylammonium molybdenyl pentachloride (JAMES and WARDLAW), 2737.

C_7 Group.

C_7H_5N Benzonitrile, electrical conductivity of uni-univalent salts in (MARTIN), 3270.

C_7H_7F Benzyl fluoride, preparation and properties of (C. K. and E. H. INGOLD), 2249.

C_7H_8O *m*-Cresol, influence of electrolytes on solubility of, in water (CARTER and HARDY), 127.

$C_7H_8O_3$ 5-Methyl*dicyclo*pentan-3-one-1-carboxylic acid (GOSS and INGOLD), 1278.

$C_7H_{12}O$ *cyclo*Hexanealdehyde, condensation of malonic acid and (SIRCAR), 54.

Suberone, preparation of (VOGEL), 2032.

$C_7H_{12}O_2$ β-Ethylvalerolactone, and its silver salt (SIRCAR), 902.

β-Methyl-β-ethylbutyrolactone, and its silver salt (SIRCAR), 901.

$C_7H_{12}O_4$ Ethyl malonate, sodium salt, action of dibromotetracarboxylic esters on (LENNON and PERKIN), 1513.

*l-iso*Propylsuccinic acid, and its salts (HENRY and PAGET), 78.

$C_7H_{12}O_5$ Dimethyl γ-xylonolactone (HAWORTH and PORTER), 616.

$C_7H_{14}O_2$ *n*-Amyloxyacetic acid (RULE, HAY, and PAUL), 1356.

7 III

$C_7H_4O_2Br_2$ Dibromohydroxybenzaldehydes (HODGSON and JENKINSON), 2275.

$C_7H_4O_6N_2$ 3:5-Dinitrosalicylaldehyde (LOVETT and ROBERTS), 1978.

C_7H_5OCl Benzoyl chloride, action of diazomethane with (BRADLEY and ROBINSON), 1310.

C_7H_6ClI 3-Chloro-5-iodotoluene (MCALISTER and KENNER), 1915.

C_7H_6BrI 3-Bromo-5-iodotoluene (MCALISTER and KENNER), 1914.

$C_7H_7ON_3$ 1-Methoxy-1:2:3-benztriazole (BRADY and REYNOLDS), 198.

1-Methyl-1:2:3-benztriazole 1-oxide (BRADY and REYNOLDS), 198.

$C_7H_7O_2N$ Phenylnitromethane, constitution and substitution of (FLÜRSCHEIM and HOLMES), 458.

$C_7H_7O_3N$ *p*-Nitroanisole, condensation of chloral with (CHATTAWAY and CALVET), 2913.
C_7H_8ON Benzaldoxime, nitration of (BRADY and MILLER), 337.
$C_7H_8O_3S$ Toluene-*p*-sulphonic acid, ammonium salt (CLEMO and WATSON), 726.
$C_7H_8Br_2Se$ Phenyl methyl selenide dibromide (EDWARDS, GAYTHWAITE, KENYON, and PHILLIPS), 2300.
$C_7H_8I_2Se$ Phenyl methyl selenide di-iodide (EDWARDS, GAYTHWAITE, KENYON, and PHILLIPS), 2300.
$C_7H_9O_3N$ 5 Methyl*dicyclo*pentan-3-one-1-carboxylic acid oxime (GOSS and INGOLD), 1273.
$C_7H_9O_3Sb$ *p*-Tolylstibinic acid (GODDARD and YARSLEY), 721.
$C_7H_{10}N_2S$ Methylthiolphenylhydrazines (HODGSON and HANDLEY), 1884.
$C_7H_{13}O_2Tl$ Thallium dimethyl acetylacetone (MENZIES, SIDGWICK, CUTCLIFFE, and FOX), 1289.
$C_7H_{14}O_3N_4$ Ethyl acetoacetate δ-aminosemicarbazone (MUNRO and WILSON), 1260.
$C_7H_{16}O_4S_2$ Sulphonal, parachor for (FREIMAN and SUGDEN), 268.
$C_7H_{17}NCl$ Methyl-β-chloroethyldiethylammonium chloride (GOUGH and KING), 2437.

7 IV

$C_7H_3O_4NBr_2$ Dibromonitrohydroxybenzaldehydes (HODGSON and JENKINSON), 2278.
$C_7H_3O_6N_2Cl$ Chlorodinitrohydroxybenzaldehydes (HODGSON and JENKINSON), 2272.
$C_7H_3O_6N_2Br$ Bromodinitrohydroxybenzaldehydes (HODGSON and JENKINSON), 2277.
$C_7H_3O_6N_2I$ Iododinitrohydroxybenzaldehydes (HODGSON and JENKINSON), 2279.
$C_7H_4O_2ClI$ 3-Chloro-5-iodobenzoic acid (MCALISTER and KENNER), 1915.
$C_7H_4O_2Cl_2S$ *o*-Sulphinobenzoic acid dichloride (PRICE and SMILES), 2861.
$C_7H_4O_2BrI$ 3-Bromo-5-iodobenzoic acid (MCALISTER and KENNER), 1915.
Bromoiodohydroxybenzaldehydes (HODGSON and JENKINSON), 2279.
$C_7H_4O_4NCl$ Chloronitrohydroxybenzaldehydes (HODGSON and JENKINSON), 2273.
5-Chloro-3-nitrosalicylaldehyde (LOVETT and ROBERTS), 1978.
$C_7H_4O_4NBr$ Bromonitrohydroxybenzaldehydes (HODGSON and JENKINSON), 2277.
$C_7H_4O_4NI$ 5-Iodo-3-nitrobenzoic acid (MCALISTER and KENNER), 1914.
Iodonitrohydroxybenzaldehydes (HODGSON and JENKINSON), 2279.
$C_7H_4O_6N_5Br$ 4-Bromo-2:3:6-trinitrophenylmethylnitroamine (CLEMO and SMITH), 2422.
$C_7H_5O_2N_2S$ 2-Nitro-4-thiocyanoaniline (CHALLENGER and PETERS), 1372.
$C_7H_5O_2N_2Se$ 2-Nitro-4-selenocyanoaniline (CHALLENGER and PETERS), 1375.
$C_7H_5O_5N_4Br$ 4-Bromo-2:6-dinitrophenylmethylnitrosoamine (CLEMO and SMITH), 2421.
$C_7H_5O_7N_2As$ Nitrobenzoxazolone-5-arsinic acids (BALABAN), 3071.
$C_7H_6ON_2S$ 5-Methoxybenzene 2:1-diazosulphide (HODGSON and HANDLEY), 626.
$C_7H_6ON_3Cl$ 3-Chloroanisole-2-diazoimide (HODGSON and KERSHAW), 193.
$C_7H_6O_2NCl$ Nitrobenzyl chlorides, velocity of reaction of trimethylamine with (NORRISH and SMITH), 130.
$C_7H_6O_2NBr$ 5-Bromo-3-aminobenzoic acid (MCALISTER and KENNER), 1915.
$C_7H_6O_2NF$ *p*-Nitrobenzyl fluoride (C. K. and E. H. INGOLD), 2260.
$C_7H_6O_3NCl$ 5-Chloro-4-nitroso-3-hydroxyanisole (HODGSON and WIGNALL), 330.
$C_7H_6O_3NBr$ 2-Bromo-4-nitroanisole (BURNS, MCCOMBIE, and SCARBOROUGH), 2934.
$C_7H_6O_3NF$ Fluoronitrophenyl methyl ethers (HODGSON and NIXON), 1880.

$C_7H_6O_4NCl$ 5-Chloro-4-nitro-3-hydroxyanisole (HODGSON and WIGNALL), 330.
$C_7H_6O_4N_3Br$ 4-Bromo-2:6-dinitromethylaniline (CLEMO and SMITH), 2421.
$C_7H_6O_5NAs$ Benzoxazolone-5-arsinic acid (BALABAN), 3071.
$C_7H_6O_6NAs$ 3-Nitro-4-hydroxy-5-carboxyphenylarsinic acid (NEWBERY, PHILLIPS, and STICKINGS), 3062.
$C_7H_7O_2NCl_2$ 3-Chloro-5-aminobenzoic acid hydrochloride (MCALISTER and KENNER), 1915.
$C_7H_7O_2ClS$ *p*-Toluenesulphonyl chloride, parachor for (FREIMAN and SUGDEN), 267.
$C_7H_7O_2IS$ 2-Iodophenylmethylsulphone (BARBER and SMILES), 1144.
$C_7H_7O_3IS$ Iodotoluenesulphonic acids, and its salts (BARBER and SMILES), 1144.
$C_7H_7O_3SLi$ Benzaldehyde lithium hydrogen sulphate (FRIEND and POUNDER), 2248.
$C_7H_7O_4N_2As$ 1-Aminobenzoxazole-4-arsinic acid (STICKINGS), 3133.
$C_7H_7O_4NSe$ 2-Nitro-*p*-tolueneseleninic acid (CHALLENGER and PETERS), 1369.
$C_7H_7O_5N_2As$ 6-Aminobenzoxazolone-5-arsinic acid (BALABAN), 3072.
C_7H_8ONCl 3-Chloro-2-aminoanisole, and its salts (HODGSON and KERSHAW), 191.
C_7H_8OClP Phenylmethylphosphinyl chloride (GIBSON and JOHNSON), 96.
$C_7H_8O_3N_2S$ 6-Nitro-3-thioanisidine (HODGSON and HANDLEY), 164.
$C_7H_8O_3N_2As$ 2-Aminobenziminazole-5-arsinic acid (STICKINGS), 3133.
$C_7H_8O_6NAs$ 3-Amino-4-hydroxy-5-carboxyphenylarsinic acid (NEWBERY, PHILLIPS, and STICKINGS), 3062.
C_7H_8BrISe Phenyl methyl selenide bromo-iodide (EDWARDS, GAYTHWAITE, KENYON, and PHILLIPS), 2300.
$C_7H_9ON_2Cl$ 3-Chloroanisyl-2-hydrazine, hydrochloride of (HODGSON and KERSHAW), 193.
$C_7H_9O_4N_2As$ *p*-Carbamidophenylarsinic acid (STICKINGS), 3133.
$C_7H_9O_5N_2As$ 5-Carbamido-2-hydroxyphenylarsinic acid (STICKINGS), 3133.
$C_7H_{15}NCl_2As$ β-Piperidinoethyldichloroarsine hydrochloride (GOUGH and KING), 2436.
$C_7H_{15}NI_2As$ β-Piperidinoethyldi-iodoarsine hydriodide (GOUGH and KING), 2436.
$C_7H_{16}O_3NAs$ β-Piperidinoethylarsinic acid, and its hydrochloride (GOUGH and KING), 2436.
$C_7H_{17}O_3N_2As$ γ-Piperazinopropylarsinic acid, and its dihydrochloride (GOUGH and KING), 2445.
$C_7H_{17}NClI$ Methyl-β-chloroethyldiethylammonium iodide (GOUGH and KING), 2437.

7 V

$C_7H_3O_2N_2ClSe$ 2-Nitro-*p*-chlorophenyl selenocyanate (CHALLENGER and PETERS), 1371.
$C_7H_3O_2N_2BrS$ 4-Bromo-3-nitrophenyl thiocyanate (CHALLENGER and PETERS), 1373.
$C_7H_3O_4NBrI$ Bromoiodonitrohydroxybenzaldehydes (HODGSON and JENKINSON), 2279.
$C_7H_6O_3NClS$ 3-Chloro-4-nitrothioanisole (HODGSON and HANDLEY), 166.
$C_7H_6O_3ClIS$ Iodotoluenesulphonyl chlorides (BARBER and SMILES), 1144.

C_8 Group.

$C_8H_8O_3$ Anisic acid, condensation of chloral with (CHATTAWAY and CALVET), 2913.
$C_8H_8Cl_2$ Dichloro-*o*-xylenes (HINKEL, AYLING, and BEVAN), 1874.
$C_8H_9N_3$ Dimethyl-1:2:3-benztriazoles (BRADY and REYNOLDS), 202.
C_8H_9Cl ω-Chloroxylene, nitration of (INGOLD and ROTHSTEIN), 1278.

C_8H_9Br ω-Bromoxylene, nitration of (INGOLD and ROTHSTEIN), 1278.
$C_8H_{10}O_3$ 1-Carboxy*cyclo*pentane-1-acetic anhydride (VOGEL), 2022.
*cyclo*Pentane-1-acetic-1-carboxylic anhydride (BARDHAN), 2600.
$C_8H_{10}O_8$ Diacetyltartaric acid, rotation dispersion of, and its esters (AUSTIN), 1825.
$C_8H_{12}O_3$ γ-Hydroxy-*aa*β-trimethyl-Δβ-pentenoic lactone (BARDHAN), 2616.
β-*cyclo*Pentane*spiro*butyrolactone, and its silver salt (SIRCAR), 902.
$C_8H_{12}O_4$ α′-Hydroxy-*aa*β-trimethylglutarolactone (BARDHAN), 2620.
Methyl caronate (HARIHARAN, MENON, and SIMONSEN), 438.
*cyclo*Pentylmalonic acid (VOGEL), 2022.
α-*iso*Propylglutaconic acids, isomeric (HARIHARAN, MENON, and SIMONSEN), 431.
Acid, and its salts, from oxidation of α-phellandrene (HENRY and PAGET), 77.
$C_8H_{12}O_5$ α-*iso*Propylacetonedicarboxylic acid (HARIHARAN, MENON, and SIMONSEN), 436.
$C_8H_{14}O_2$ ββ-Diethylbutyrolactone, and its silver salt (SIRCAR), 901.
β-Methyl-β-ethylvalerolactone, and its silver salt (SIRCAR), 903.
*aa*β-Trimethyl-Δβ-pentenoic acid, and its silver salt (BARDHAN), 2615.
$C_8H_{14}O_3$ αββ-Trimethyl-lævulic acid (BARDHAN), 2613.
$C_8H_{14}O_4$ Suberic acid, catalytic decomposition of (VOGEL), 2032.
$C_8H_{14}O_5$ ββ′-Diacetoxyethyl ether (MACLEOD), 3092.
Trimethyl-δ-lyxonolactone (HIRST and SMITH), 3152.
Trimethyl γ-xylonolactone (HAWORTH and PORTER), 617.
$C_8H_{16}O_3$ *n*-Hexyloxyacetic acid (RULE, HAY, and PAUL), 1356.
$C_8H_{16}O_5$ Trimethyl lyxose (HIRST and SMITH), 3151.
$C_8H_{17}N$ 2:2:6-Trimethylpiperidine, and its salts (GOUGH and KING), 2444.
$C_8H_{18}O_5$ Trimethyl methyl-lyxoside (HIRST and SMITH), 3151.

8 III

$C_8H_3N_2Cl_5$ *aa*β-Trichloro-β-2:4:6-trichlorobenzeneazoethylene (CHATTAWAY and DALDY), 2760.
$C_8H_3N_2Cl_5$ *aa*-Dichloro-β-2:4:6-trichlorobenzeneazoethylene (CHATTAWAY and DALDY), 2758.
$C_8H_3N_2Cl_7$ Chloral ω-chloro-2:4:6-trichlorophenylhydrazone (CHATTAWAY and DALDY), 2760.
$C_8H_4N_2S_2$ *p*-Dithiocyanobenzene, preparation and nitration of (CHALLENGER and PETERS), 1371.
$C_8H_5O_3N_3$ ω-Diazo-*p*-nitroacetophenone (BRADLEY and SCHWARZENBACH), 2907.
$C_8H_5O_4Br$ 4-Bromophthalic acid, preparation of (BAKER), 2829.
$C_8H_5O_9N_5$ Tetranitroacetanilide (FLÜRSCHEIM and HOLMES), 3046.
$C_8H_6ON_2$ Diazoacetophenone (BRADLEY and ROBINSON), 1316.
$C_8H_6OCl_2$ ω-Chloro-*m*-toluoyl chloride (TITLEY), 2582.
$C_8H_6OBr_2$ ω-Bromo-*p*-toluoyl bromide (TITLEY), 2581.
$C_8H_6O_2N_2$ 2:3-Dihydroxyquinoxaline, and its sodium salt (PHILLIPS), 2397.
$C_8H_6O_3N_2$ 5-Nitroethenyl-*o*-aminophenol (NEWBERY and PHILLIPS), 121.
$C_8H_6O_4N_2$ Nitro-3-hydroxy-1:4-ben*ziso*oxazines (NEWBERY and PHILLIPS), 3048.
$C_8H_6O_6N_2$ Methyl 2:3-dinitrobenzoate (BRADY, DAY, and ALLAM), 981.
$C_8H_7O_2N_3$ 1-Acetoxy-1:2:3-benztriazole (BRADY and REYNOLDS), 197.
$C_8H_7O_3I$ 2-Iodo-3-methoxybenzoic acid (KENNER and TURNER), 2341
C_8H_7NS 1-Methylbenzthiazole, salts of (CLARK), 2315.
C_8H_7NSe 1-Methylbenzselenazole, and its salts (CLARK), 2316.
$C_8H_8ON_2$ 5-Aminoethenyl-*o*-aminophenol (NEWBERY and PHILLIPS), 122.

$C_8H_8OCl_2$ Dichloro-*o*-4-xylenols (HINKEL, AYLING, and BEVAN), 2532.
$C_8H_8O_2N_2$ 8-Amino-3-hydroxy-1:4-benz*iso*oxaziue, and its hydrochloride (BALABAN), 3070.
Amino-3-hydroxy-1:4-benz*iso*oxazines, and their salts (NEWBERY and PHILLIPS), 3048.
$C_8H_8O_2Se$ *p*-Carboxyphenyl methyl selenide (GAYTHWAITE, KENYON, and PHILLIPS), 2286.
$C_8H_8O_3Se$ *p*-Carboxyphenyl methyl selenoxide (GAYTHWAITE, KENYON, and PHILLIPS), 2286.
$C_8H_8O_4N_2$ Dinitroethylbenzenes (BRADY, DAY, and ALLAM), 980.
6-Nitro-2-acetamidophenol (NEWBERY and PHILLIPS), 3050.
$C_8H_8O_4Ni$ Methyl hydroxynickelosalicylate (DOAK and PACKER), 2768.
$C_8H_8O_8N_4$ 2:4:6-Trinitro-5-aminoresorcinol dimethyl ether (FLÜRSCHEIM and HOLMES), 3044.
$C_8H_9ON_3$ 1:6-Dimethyl-1:2:3-bentriazole 1-oxide (BRADY and REYNOLDS), 201.
1-Methoxy-6-methyl-1:2:3-benztriazole (BRADY and REYNOLDS), 201.
C_8H_9OCl 3-Chloro-*o*-4-xylenol (HINKEL, AYLING, and BEVAN), 2531.
C_8H_9OBr β-Hydroxy-β-phenylethyl bromide (READ and REID), 1488.
$C_8H_9O_3S$ α- and β-Phenylethanesulphonic acids, barium salts (ASHWORTH and BURCKHARDT), 1798.
$C_8H_9O_4N_2$ Dinitro-4-aminoethylbenzenes (BRADY, DAY, and ALLAM), 981.
$C_8H_9NCl_2$ Dichloro-*o*-xylidines (HINKEL, AYLING, and BEVAN), 1876.
$C_8H_{10}O_2N_2$ Ethyl urocanate, picrate of (HUBBALL and PYMAN), 26.
$C_8H_{10}O_2S$ Benzylmethylsulphone, parachor for (FREIMAN and SUGDEN), 267.
$C_8H_{10}O_2S_2$ Dimethylthiolbenzene disulphoxides (BELL and BENNETT), 3191.
$C_8H_{10}N_2Cl_2$ Dichlorodiamino-*o*-xylenes (HINKEL, AYLING, and BEVAN), 1877.
$C_8H_{10}Br_2Se$ Phenyl ethyl selenide dibromide (EDWARDS, GAYTHWAITE, KENYON, and PHILLIPS), 2302.
$C_8H_{11}ON$ 3-Amino-*o*-4-xylenol (HINKEL, AYLING, and BEVAN), 2531.
$C_8H_{11}O_2P$ Methyl phenylmethylphosphinate (GIBSON and JOHNSON), 97.
$C_8H_{11}N_2Cl$ Chloroaminodimethylanilines (CLEMO and SMITH), 2420.
$C_8H_{11}N_2Br$ 4-Bromo-2-aminodimethylaniline (CLEMO and SMITH), 2420.
$C_8H_{11}NS_2$ 2:4-Dimethylthiolaniline, and its hydrochloride (HODGSON and HANDLEY), 164.
$C_8H_{15}ON_3$ Methylmesityl oxide semicarbazone (BARDHAN), 2614.
$C_8H_{15}O_3Tl$ Ethyl thallium dimethyl acetoacetate (MENZIES, SIDGWICK, CUTCLIFFE, and FOX), 1290.
$C_8H_{16}O_2S$ *n*-Octanesulphinic acid, ferric salt (FENTON and INGOLD), 3130.
$C_8H_{16}O_2Pt$ Trimethylplatinum acetylacetone (MENZIES), 565.
$C_8H_{18}O_4S_2$ Trional, parachor from (FREIMAN and SUGDEN), 269.

8 IV

$C_8H_2N_2Cl_2Br_4$ αα-Dichloro-β-bromo-β-2:4:6-tribromobenzeneazoethylene (CHATTAWAY and DALDY), 2762.
$C_8H_2N_2Cl_3Br_3$ ααβ-Trichloro-β-2:4:6-tribromobenzeneazoethylene (CHATTAWAY and DALDY), 2762.
$C_8H_2N_2Cl_5Br$ αα-Dichloro-α-bromo-β-2:4:6-trichlorobenzeneazoethylene (CHATTAWAY and DALDY), 2760.
$C_8H_3N_2Cl_2Br_3$ αα-Dichloro-β-2:4:6-tribromobenzeneazoethylene (CHATTAWAY and DALDY), 2762.
$C_8H_4O_2N_2Cl_4$ Glyoxylic acid ω-chloro-2:4:6-trichlorophenylhydrazone (CHATTAWAY and DALDY), 2761.
$C_8H_4O_4N_2Br$ *m*-Nitrophenylbromocyanonitromethane (FLÜRSCHEIM and HOLMES), 476.

$C_8H_4N_2SSe$ *p*-Thiocyanoselenocyanobenzene, preparation and nitration of (CHALLENGER and PETERS), 1372.

$C_8H_5O_2N_2Cl_3$ Glyoxylic acid 2:4:6-trichlorophenylhydrazone (CHATTAWAY and DALBY), 2760.

$C_8H_5O_2N_2Br_3$ Glyoxylic acid 2:4:6-tribromophenylhydrazone (CHATTAWAY and DALBY), 2762.

C_8H_6ONCl 3-Chloro-2-cyanoanisole (HODGSON and KERSHAW), 192.

$C_8H_6O_2NCl$ ω-Chloronitrostyrenes, alkaline hydrolysis of (DANN, HOWARD, and DAVIES), 605.

$C_8H_6O_2NBr$ ω-Bromonitrostyrenes, alkaline hydrolysis of (DANN, HOWARD, and DAVIES), 605.

$C_8H_6O_2N_2S$ Nitro-*o*-tolyl thiocyanates (CHALLENGER and PETERS), 1368.

$C_8H_6O_2N_2Se$ Nitro-*p*-tolyl selenocyanates (CHALLENGER and PETERS), 1370.

$C_8H_6O_2ClI$ Methyl 3-chloro-5-iodobenzoate (MCALISTER and KENNER), 1915.

$C_8H_6O_2BrI$ Methyl 3-bromo-5-iodobenzoate (MCALISTER and KENNER), 1915.

$C_8H_6O_2NAs$ 3-Hydroxy-1:4-benz*iso*oxazine 6-arsenoxide (NEWBERY, PHILLIPS, and STICKINGS), 3056.

$C_8H_6O_4N_2Cl_2$ Dichlorodinitro-*o*-xylenes (HINKEL, AYLING, and BEVAN), 1876.

$C_8H_6O_5N_2Cl$ 2:4-Dinitrophenylchloroacetamide (FAIRBOURNE and FAWSON), 1079.

$C_8H_6O_5N_3Br$ 2:4-Dinitrophenylbromoacetamide (FAIRBOURNE and FAWSON), 1079.

$C_8H_6O_6N_3Cl$ Chlorodinitrohydroxybenzaldehyde semicarbazones (HODGSON and JENKINSON), 2274.

$C_8H_6O_6N_3Br$ Bromodinitrohydroxybenzaldehyde semicarbazones (HODGSON and JENKINSON), 2277.

$C_8H_6O_6N_3I$ Iodinitrohydroxybenzaldehyde semicarbazones (HODGSON and JENKINSON), 2279.

$C_8H_7O_2NCl_2$ Dichloronitro-*o*-xylenes (HINKEL, AYLING, and BEVAN), 1876.

$C_8H_7O_3N_2As$ 8-Amino-3-hydroxy-1:4-benz*iso*oxazine 6-arsenoxide, hydrochloride of (NEWBERY, PHILLIPS, and STICKINGS), 3059.

$C_8H_7O_4N_2Cl$ 3-Nitro-2-chloroacetamidophenol (NEWBERY and PHILLIPS), 3048.

$C_8H_7O_4N_4Cl$ Chloronitrohydroxybenzaldehyde semicarbazones (HODGSON and JENKINSON), 2273.

$C_8H_7O_4N_4Br$ Bromonitrohydroxybenzaldehyde semicarbazones (HODGSON and JENKINSON), 2277.

$C_8H_7O_4N_4I$ Iodonitrohydroxybenzaldehyde semicarbazones (HODGSON and JENKINSON). 2279.

$C_8H_7O_5N_2As$ 2:3-Dihydroxyquinoxalinearsinic acids (PHILLIPS), 3139.

2:4-Diketo-1:2:3:4-tetrahydro-1:3-quinazoline-7-arsinic acid (STICKINGS), 3134.

3-Nitro-4-hydroxy-5-acetamidophenylarsenoxide (NEWBERY and PHILLIPS), 2380.

$C_8H_7O_7N_2As$ Nitrohydroxy-1:4-benz*iso*oxazinearsinic acids (NEWBERY, PHILLIPS, and STICKINGS), 3057; (BALABAN), 3068.

C_8H_8ONCl *N*-Chloroacetanilide, decomposition of, by heat (BRADFIELD), 351.

C_8H_8ONBr *o*-Bromoacetanilide, nitration of (GIBSON and JOHNSON), 3092.

$C_8H_8ON_2Br$ *p*-Bromobenzaldehyde semicarbazone (INGOLD and SHOPPEE), 407.

$C_8H_8O_2NBr$ ω(1)-Bromo-3-nitro-*p*-xylene (INGOLD and ROTHSTEIN), 1220.

$C_8H_8O_2NAs$ 2:3-Dihydro-1:4-benz*iso*oxazine-6-arsenoxide (NEWBERY, PHILLIPS, and STICKINGS), 3064.

$C_8H_8O_2N_2S$ Benziminazole-2-thioglycollic acid (STEPHEN and WILSON), 1420.

$C_8H_8O_2Br_2Se$ *p*-Carboxyphenyl methyl selenide (GAYTHWAITE, KENYON, and PHILLIPS), 2286.

Phenylselenoglycollic acid dibromide (EDWARDS, GAYTHWAITE, KENYON, and PHILLIPS), 2298.

$C_8H_8O_3NCl$ 5-Chloro-3-nitro-*o*-4-xylenol (HINKEL, AYLING, and BEVAN), 2531.

$C_8H_8O_3NAs$ 5-Acetamido-2-hydroxyphenylarsenoxide (NEWBERY and PHILLIPS), 2380.

$C_8H_8O_4NCl$ 5-Chloro-2- and -4-nitroresorcinols (HODGSON and WIGNALL), 331.

$C_8H_8O_4N_2Br$ Bromodinitrodimethylanilines (CLEMO and SMITH), 2421.

$C_8H_8O_5NAs$ 3-Hydroxy-1:4-benz*iso*oxazinearsinic acids (NEWBERY, PHILLIPS, and STICKINGS), 3054.

$C_8H_8O_6NAs$ 3:7-Dihydroxy-1:4-benz*iso*oxazine-6-arsinic acid (NEWBERY, PHILLIPS, and STICKINGS), 3058.

$C_8H_8N_2Br_2S$ 5-Bromo-1-amino-3-methylbenzthiazole hydrobromide (HUNTER and STYLES), 3023.

$C_8H_8N_2Br_4S$ 1-Amino-3-methylbenzthiazole tetrabromide (HUNTER and STYLES), 3023.

5-Bromo-1-amino-3-methylbenzthiazole dibromide hydrobromide (HUNTER and STYLES), 3025.

C_8H_9OClS Chloro-5-methoxythioanisoles (HODGSON and HANDLEY), 627.

$C_8H_9O_3N_2Br$ Bromonitrodimethylanilines (CLEMO and SMITH), 2420.

$C_8H_9O_3N_2As$ 3-Amino-5-acetamido-4-hydroxyphenylarsenoxide, salts of (NEWBERY and PHILLIPS), 2377.

Methylbenziminazolearsinic acids (PHILLIPS), 3136.

$C_8H_9O_5NS$ Ethyl *p*-nitrobenzenesulphonate (BELL), 2776.

Nitro-5-methoxyphenylmethylsulphones (HODGSON and HANDLEY), 627.

$C_8H_9O_5N_2As$ Aminohydroxy-1:4-benz*iso*oxazinearsinic acids (NEWBERY, PHILLIPS, and STICKINGS), 3057; (BALABAN), 3069.

$C_8H_9O_7N_2As$ 3-Nitro-5-acetamido-2-hydroxyphenylarsinic acid (NEWBERY and PHILLIPS), 2376.

$C_8H_9O_8N_2As$ 2-Nitro-4-ω-hydroxyacetamido-3-hydroxyphenylarsinic acid (BALABAN), 3069.

$C_8H_9N_2BrS$ 1-Amino-3-methylbenzthiazole hydrobromide (HUNTER and STYLES), 3023.

$C_8H_9N_2Br_3S$ 1-Amino-3-methylbenzthiazole dibromide hydrobromide (HUNTER and STYLES), 3022.

$C_8H_{10}ONCl$ Chloroamino-*o*-4-xylenols (HINKEL, AYLING, and BEVAN), 2531.

$C_8H_{10}O_2NAs$ Acetamidohydroxyphenylarsines (NEWBERY and PHILLIPS), 2381.

$C_8H_{10}O_4NAs$ 2:3-Dihydro-1:4-benz*iso*oxazine-6-arsinic acid (NEWBERY, PHILLIPS, and STICKINGS), 3063.

$C_8H_{10}O_5NAs$ 3-Hydroxy-1:4-benz*iso*oxazine-7-arsinic acid (BALABAN), 3068.

$C_8H_{10}O_6NAs$ 5-Acetamido-2:4-dihydroxyphenylarsinic acid (NEWBERY, PHILLIPS, and STICKINGS), 3058.

$C_8H_{11}O_5N_2As$ 2-Amino-4-acetamido-3-hydroxyphenylarsinic acid, and its salts (BALABAN), 812.

3-Amino-5-acetamidohydroxyphenylarsinic acids (NEWBERY and PHILLIPS), 2376.

$C_8H_{11}O_6N_2As$ 2-Amino-4-ω-hydroxyacetamido-3-hydroxyphenylarsinic acid (BALABAN), 3069.

$C_8H_{14}O_2N_2S$ Ethyl 1:4:5:6-tetrahydropyrimidine-2-thioglycollate (STEPHEN and WILSON), 1420.

$C_8H_{18}O_3NAs$ γ-Piperidinopropylarsinic acid, and its hydrochloride (GOUGH and KING), 2443.

$C_8H_{20}OI_2Te_2$ Diethyltelluronium α-oxyiodide (GILBERT and LOWRY), 3183.

$C_8H_{20}O_6N_2As_2$ *NN'*-Piperazine-di-ββ'-ethylarsinic acid and its dihydrochloride (GOUGH and KING), 2436.

8 V

$C_8H_3O_2N_3SSe$ 2-Nitro-4-thiocyanophenyl selenocyanate (CHALLENGER and PETERS), 1373.

$C_8H_4O_2N_8S_8Mo$ Tetrahydrogen dimolybdenum trioxyoctathiocyanate, salts of (JAMES and WARDLAW), 2733.

C_8H_6ONClS 3-Chloro-2-thiocyanoanisole (HODGSON and KERSHAW), 192.

$C_8H_6ONCl_2I$ 2:4-Dichloro-6-iodoacetanilide (BRADFIELD, ORTON, and ROBERTS), 783.

$C_8H_6ONCl_2F$ 3-Fluoro-4:6-dichloroacetanilide (INGOLD and VASS), 422.

$C_8H_6O_3N_2ClI$ Chloroiodo-6-nitroacetanilides (BRADFIELD, ORTON, and ROBERTS), 784.

$C_8H_6O_3N_2BrI$ Bromoiodo-6-nitroacetanilides (BRADFIELD, ORTON, and ROBERTS), 784.

$C_8H_6O_5NCl_2As$ 2-Nitrophenoxyacetic acid 4-dichloroarsine (NEWBERY, PHILLIPS, and STICKINGS), 3056.

C_8H_7ONBrI 2-Bromo-4-iodoacetanilide (BRADFIELD, ORTON, and ROBERTS), 783.

C_8H_7ONClF 3-Fluoro-6-chloroacetanilide (INGOLD and VASS), 422.

$C_8H_7O_5NClAs$ 8-Chloro-3-hydroxy-1:4-benzoxazine-6-arsinic acid (NEWBERY, PHILLIPS, and STICKINGS), 3060.

$C_8H_8O_2NCl_2As$ Acetamidohydroxyphenyldichloroarsines (NEWBERY and PHILLIPS), 2380.

$C_8H_8O_3N_2ClAs$ 8-Amino-3-hydroxy-1:4-benz*iso*oxazine-6-hydroxychloroarsine, hydrochloride of (NEWBERY, PHILLIPS, and STICKINGS), 3059.

$C_8H_8O_7N_2ClAs$ 3-Nitro-5-chloroacetamido-4-hydroxyphenylarsinic acid (NEWBERY, PHILLIPS, and STICKINGS), 3059.

$C_8H_9O_2N_2Cl_2As$ 3-Amino-5-acetamido-4-hydroxyphenyldichloroarsine, hydrochloride of (NEWBERY and PHILLIPS), 2377.

$C_8H_9O_2N_2I_2As$ 3-Amino-5-acetamido-4-hydroxyphenyldi-iodoarsine, hydriodide of (NEWBERY and PHILLIPS), 2377.

$C_8H_9O_4NClAs$ 3-Chloro-6-acetamidophenylarsinic acid, and its magnesium salt (BALABAN), 812.

$C_8H_{10}O_4N_2ClAs$ 6-Glycineamide-3-chlorophenylarsinic acid, and its salts (BALABAN), 813.

$C_8H_{24}ON_2Cl_5Mo$ Bisdiethylammonium molybdenyl pentachloride (JAMES and WARDLAW), 2737.

Ditetramethylammonium molybdenyl pentachloride (JAMES and WARDLAW), 2737.

8 VI

$C_8H_6ONClBrI$ Chlorobromoiodoacetanilides (BRADFIELD, ORTON, and ROBERTS), 783.

C_9 Group.

$C_9H_8O_2$ Phenylpropiolic acid, addition of bromine and chlorine to (HANSON and JAMES), 2979.

$C_9H_8O_2$ Cinnamic acid, addition of mixtures of bromine and chlorine to (HANSON and JAMES), 1955.

$C_9H_8O_4$ Homophthalic acid, action of phosphorus pentachloride on (DAVIES and POOLE), 1616; copper salt (POOLE), 1379.

4-Methoxy*iso*phthalaldehydic acid (CHATTAWAY and CALVET), 2916.

Phthalic acid, separation of homophthalic acid from (POOLE), 1378.

$C_9H_8O_5$ 4-Methoxy*iso*phthalic acid (CHATTAWAY and CALVET), 2916.

$C_9H_{10}O_2$ 5-*cyclo*Pentane*spirocyclo*penten-3-ol-1:4-dione (GOSS), 1308.

$C_9H_{10}O_5$ Methyl hydrogen 5-methyl*dicyclo*penten-3-oldicarboxylate (GOSS and INGOLD), 1273.

$C_9H_{12}O_3$ *cyclo*Pentylideneacetoacetic acid (JUPP, KON, and LOCKTON), 1642.

$C_9H_{14}O$ α-Methyl-Δ^1-*cyclo*pentenylacetone (BARDHAN), 2604.

α-Methyl*cyclo*pentylideneacetone (BARDHAN), 2603.

Phorone, ring-chain tautomerism in derivatives of (SUGDEN), 410.

$C_9H_{14}O_2$ *cyclo*Hexane*spiro*butyrolactone, and its silver salt (SIRCAR), 57, 902.
*β-cyclo*Hexylacrylic acid, and its salts (SIRCAR), 55.
*β-cyclo*Pentane*spiro*valerolactone, and its silver salt (SIRCAR), 903.
$C_9H_{14}O_3$ 1-Acetyl*cyclo*pentane-1-acetic acid (BARDHAN), 2601.
$C_9H_{14}O_4$ Methyl *cyclo*pentane-1-acetic-1-carboxylate (BARDHAN), 2600.
$C_9H_{14}O_6$ *aα*-Dihydroxy*cyclo*pentane-1:1-diacetic acid (GOSS), 1310.
$C_9H_{14}N_2$ *αγ*-Diamino-*β*-phenylpropane, and its salts (JACKSON and KENNER), 1658.
$C_9H_{16}O_2$ Allyl hexoate (DEULOFEU), 528.
ββ-Diethylvalerolactone, and its silver salt (SIRCAR), 903.
Hydroxy-2:2:3:3-tetramethyl*cyclo*pentanone (SHOPPEE), 1666.
$C_9H_{18}O_3$ *n*-Heptyloxyacetic acid (RULE, HAY, and PAUL), 1356.

9 III

$C_9H_4O_2Cl_4$ 3:3:4:4-Tetrachloro-3:4-dihydro*iso*coumarin (DAVIES and POOLE), 1620.
$C_9H_5O_2Cl$ 3-Chloro*iso*coumarin (DAVIES and POOLE), 1618.
$C_9H_5N_2Br_3$ 2-*ω*-Tribromomethylquinoxaline (BENNETT and WILLIS), 1974.
$C_9H_6O_2Cl_4$ *aaββ*-Tetrachloro-*β*-phenylpropionic acid (HANSON and JAMES), 2985.
$C_9H_7O_2N$ Methyl *o*-cyanobenzoate, action of magnesium phenyl bromide on (BOYD and LADHAMS), 2089.
$C_9H_7O_3N$ Methylphthaloximes (BRADY, BAKER, GOLDSTEIN, and HARRIS), 539.
$C_9H_8O_2N_2$ *o*-Phenylenemalonamide, sodium salt (PHILLIPS), 2398.
C_9H_8ClBr *p*-Chlorocinnamyl bromide (BURTON), 1656.
C_9H_9OCl *p*-Chlorocinnamyl alcohol (BURTON), 1655.
α-p-Chlorophenylallyl alcohol (BURTON), 1655.
$C_9H_9O_2N_3$ 1-Acetoxy-6-methyl-1:2:3-benztriazole (BRADY and REYNOLDS), 200.
$C_9H_9O_6N_3$ *O*-Methyl-3:5-dinitro-4-methoxybenzaldoxime (BRADY and MILLER), 341.
C_9H_9NS 1-Ethylbenzthiazole, and its picrate (CLARK), 2319.
C_9H_9NSe 2-Methyl-1-methylenebenzselenazoline (CLARK), 2317.
$C_9H_{10}O_2S$ *m*-Ethylthiolbenzoic acid (HOLLOWAY, KENYON, and PHILLIPS), 3003.
$C_9H_{10}O_3N_2$ 2-Aminomalonanilic acid (PHILLIPS), 2398.
$C_9H_{10}O_3N_4$ 3:3′-Dimethyl-5:5′-dipyrazolonyl 1:1′-ketone (MUNRO and WILSON), 1260.
$C_9H_{10}O_3S$ Carboxyphenyl ethyl sulphoxide, and its resolution (HOLLOWAY, KENYON, and PHILLIPS), 3003.
$C_9H_{10}O_4S$ *m*-Carboxyphenylethylsulphone (HOLLOWAY, KENYON, and PHILLIPS), 3004.
$C_9H_{10}O_4Cu$ Methyl methoxycuprisalicylate (DOAK and PACKER), 2767.
$C_9H_{10}O_4Ni$ Methyl methoxynickelosalicylate (DOAK and PACKER), 2768.
$C_9H_{10}N_2S$ 1-Methylamino-3-methylbenzthiazole (HUNTER and STYLES), 3025.
$C_9H_{11}O_2N_3$ Aldehydomethylphenol semicarbazones (BELL and HENRY), 2222.
$C_9H_{11}O_2Tl$ Thallium dimethyl salicylaldehyde (MENZIES, SIDGWICK, CUTCLIFFE, and FOX), 1291.
$C_9H_{12}O_2Cl_2$ 1:1-Dichloro-2:2:3:3-tetramethyl*cyclo*pentanedione (INGOLD and SHOPPEE), 408.
$C_9H_{12}O_3S$ Ethyl *p*-toluenesulphonate, parachor for (FREIMAN and SUGDEN), 267.
$C_9H_{12}N_2S$ *o*-Tolylmethylthiocarbamides (HUNTER and STYLES), 3024.
$C_9H_{12}ON$ *p*-Dimethylaminobenzyl alcohol (CLEMO and SMITH), 2424.

$C_9H_{13}ON$ Nor-*d*-ψ-ephedrine, and its salts (SMITH), 51.

$C_9H_{13}O_2Cl$ 1-Chloro-2:2:3:3-tetramethyl-[0,1,2]-*dicyclo*pentan-4-ol-5-one (INGOLD and SHOPPEE), 408.

$C_9H_{13}O_3P$ Ethyl phenylmethylphosphinate (GIBSON and JOHNSON), 96.

$C_9H_{14}ON_2$ αγ-Diamino-β-*p*-hydroxyphenylpropane, and its dihydrobromide (JACKSON and KENNER), 1661.

3:3:4:4-Tetramethyl*cyclo*pentane-1:2-dione furazan (INGOLD and SHOPPEE), 396.

$C_9H_{14}OBr_2$ Dibromotetramethyl*cyclo*pentanone (SHOPPEE), 2363.

$C_9H_{14}O_2N_2$ αγ-Diamino-β-3:4-dihydroxyphenylpropane, and its dihydrobromide (JACKSON and KENNER), 1661.

$C_9H_{14}O_3N_2$ 4:4:5:5-Tetramethyl*cyclo*pentanetrione 1:3-dioxime (INGOLD and SHOPPEE), 391.

$C_9H_{15}ON$ β-*cyclo*Hexylacrylamide (SIRCAR), 55.

$C_9H_{15}OP$ Phenyltrimethylphosphonium hydroxide, picrate of (INGOLD, SHAW, and WILSON), 1283.

$C_9H_{15}OSb$ Phenytrimethylstibonium hydroxide, picrate of (INGOLD, SHAW, and WILSON), 1283.

$C_9H_{15}O_2N$ 2:2:3:3-Tetramethyl-[0, 1, 2]-*dicyclo*pentan-4-ol-5-one oximes (INGOLD and SHOPPEE), 394.

ααββ-Tetramethylglutarimide (INGOLD and SHOPPEE), 396.

Lactam of δ-amino-α-keto-γγ-dimethyl*iso*heptoic acid (INGOLD and SHOPPEE), 400.

Lactam of δ-amino-α-keto-ββγγ-tetramethylvaleric acid (INGOLD and SHOPPEE), 395.

$C_9H_{15}O_3N$ 1-Acetyl*cyclo*pentane-1-acetic acid oxime (BARDHAN), 2601.

Substance, from potassium cyanide and methylmesityl oxide (BARDHAN), 2614.

$C_9H_{15}O_3N_3$ 4:4:5:5-Tetramethyl*cyclo*pentanetrione 1:2:3-trioxime (INGOLD and SHOPPEE), 392.

$C_9H_{16}O_2N_2$ 3:3:4:4-Tetramethyl*cyclo*pentane-1:2-dione dioxime (INGOLD and SHOPPEE), 396.

$C_9H_{16}O_4S_2$ Pentane-αε-dithiolacetic acid (CHIVERS and SMILES), 701.

$C_9H_{17}ON$ 4:4:5:5-Tetramethyl*cyclo*pentanetrione oxime (INGOLD and SHOPPEE), 392.

Tetramethyl*cyclo*pentanone oxime (INGOLD and SHOPPEE), 398.

$C_9H_{17}ON_3$ γδ-Dimethylhexen-β-one semicarbazones (ABBOTT, KON, and SATCHELL), 2517.

ε-Methylhepten-γ-one semicarbazones (ABBOTT, KON, and SATCHELL), 2523.

$C_9H_{17}O_2Tl$ Thallium diethyl acetylacetone (MENZIES, SIDGWICK, CUTCLIFFE, and FOX), 1289.

$C_9H_{17}O_3N_3$ αββ-Trimethyl-lævulic acid semicarbazone (BARDHAN), 2613.

$C_9H_{17}O_{12}N_3$ Triaminopropane trihydrogen trioxalate (MANN), 898.

$C_9H_{19}O_2N$ Hydroxy-2:2:3:3-tetramethyl*cyclo*pentylamines, picrates of (INGOLD and SHOPPEE), 400, 404.

Tetramethyl*cyclo*pentylamines, and their salts (INGOLD and SHOPPEE), 392, 398.

9 IV

C_9H_4OClBr 3-Chloro-2-bromo-1-ketoindene (HANSON and JAMES), 2983.

$C_9H_6O_2ClBr$ Chlorobromocinnamic acid (HANSON and JAMES), 2983.

$C_9H_6O_2Cl_3Br$ αββ-Trichloro-α-bromo-β-phenylpropionic acid (HANSON and JAMES), 2985.

$C_9H_6O_3NCl_3$ αββ-Trichloro-5-nitro-2-methoxystyrene (CHATTAWAY and CALVET), 2917.

$C_9H_7O_3NCl_4$ 5-Nitro-2-methoxy-1-αββδ-tetrachloroethylbenzene (CHATTAWAY and CALVET), 2917.

$C_9H_7O_3N_3S$ 2-Nitro-4-thiocyanoacetanilide (CHALLENGER and PETERS), 1372.
$C_9H_7O_3N_2Se$ 2-Nitro-4-selenocyanoacetanilide (CHALLENGER and PETERS), 1373.
$C_9H_8O_2ClBr$ β-Chloro-α-bromo-β-phenylpropionic acid (HANSON and JAMES), 1958
$C_9H_8O_3NCl$ 3-Chloro-5-acetamidobenzoic acid (McALISTER and KENNER), 1915.
$C_9H_8O_3NBr$ 3-Bromo-5-acetamidobenzoic acid (McALISTER and KENNER), 1915.
$C_9H_8O_4NI$ Ethyl 5-iodo-3-nitrobenzoate (McALISTER and KENNER), 1914.
$C_9H_8O_7NAs$ 3-Hydroxy-8-carboxy-1:4-benz*iso*oxazine-6-arsinic acid (NEWBERY, PHILLIPS, and STICKINGS), 3062.
$C_9H_9O_6N_2As$ 6-Acetamidobenzoxazolonearsinic acids (BALABAN), 3072.
$C_9H_{10}O_2NCl$ Acetyl derivative of 3-chloro-2-aminoanisole (HODGSON and KERSHAW), 192.
$C_9H_{10}O_2SBr_2$ *m*-Carboxyphenyl ethyl sulphide and dibromide (HOLLOWAY, KENYON, and PHILLIPS), 3004.
$C_9H_{10}O_5NAs$ Hydroxymethyl-1:4-benz*iso*oxazinearsinic acids (NEWBERY, PHILLIPS, and STICKINGS), 3061.
$C_9H_{10}O_5N_2As$ 1-Amino-6-acetamidobenzoxazole-4-arsinic acid (STICKINGS), 3134.
$C_9H_{10}O_7NAs$ 3-Acetamido-4-hydroxy-5-carboxyphenylarsinic acid (NEWBERY, PHILLIPS, and STICKINGS), 3062.
$C_9H_{10}N_2Br_4S$ *s-o*-Tolylmethylthiocarbamide tetrabromide (HUNTER and STYLES), 3024.
$C_9H_{11}O_2N_3Cl$ 5-Chloro-4-nitroso-3-methoxydimethylaniline (HODGSON and WIGNALL), 332.
$C_9H_{11}O_3N_2As$ 2-Ethylbenziminazolearsinic acid (PHILLIPS), 3137.
$C_9H_{11}O_4N_2As$ 2-α-Hydroxyethylbenziminazolearsinic acids (PHILLIPS), 3137.
$C_9H_{11}N_2Br_3S$ *s-o*-Tolylmethylthiocarbamide tribromide (HUNTER and STYLES), 3024
$C_9H_{12}ONCl$ 5-Chloro-3-methoxydimethylaniline (HODGSON and WIGNALL), 331.
$C_9H_{12}O_2ClBr$ 1-Chloro-1-bromo-2:2:3:3-tetramethyl*cyclo*pentanedione (INGOLD and SHOPPEE), 409.
$C_9H_{14}O_2NAs$ *m*-Nitrophenyltrimethylarsonium hydroxide, picrate of (INGOLD, SHAW, and WILSON), 1285.
$C_9H_{14}O_2NP$ *m*-Nitrophenyltrimethylphosphonium hydroxide, picrate of (INGOLD, SHAW, and WILSON), 1283.
$C_9H_{14}O_2NSb$ *m*-Nitrophenyltrimethylstibonium hydroxide, picrate of (INGOLD, SHAW, and WILSON), 1285.
$C_9H_{21}NCl_3As$ γ-*n*-Hexylaminopropyldichloroarsine hydrochloride (GOUGH and KING), 2443.

9 V

$C_9H_5OClBrN$ 3-Chloro-2-bromo-1-ketoindene oxime (HANSON and JAMES), 2984.
$C_9H_{10}ONClS$ Chlorothioacetanisidines (HODGSON and HANDLEY), 163, 166.
$C_9H_{11}O_3NClAs$ Acetamidohydroxyphenylmethoxychloroarsines (NEWBERY and PHILLIPS), 2380.
$C_9H_{11}O_6NClAs$ 3-ω-Chlorocarbethoxyamino-4-hydroxyphenylarsinic acid (NEWBERY, PHILLIPS, and STICKINGS), 3063.

C_{10} Group.

$C_{10}H_{16}$ Limonene, oxidation of (HENRY and PAGET), 75.
α-Phellandrene, oxidation of (HENRY and PAGET), 72.

10 II

$C_{10}H_6O_5$ 4:5-Methylenedioxyhomophthalic anhydride (STEVENS and WILSON), 2827.
$C_{10}H_8S_2$ Naphthylene 1:8-disulphide (PRICE and SMILES), 2374.

$C_{10}H_8O_4$ β-*o*-Carboxyphenylpropionic acid (TITLEY), 2575.
$C_{10}H_8O_6$ 5-Carboxy-2-methoxyphenylglyoxylic acid (CHATTAWAY and CALVET), 2917.
$C_{10}H_8N_2$ Glyoxaline-4(5)-methylideneaniline (HUBBALL and PYMAN), 25.
$C_{10}H_{10}O_2$ Benzylmethylglyoxal, absorption spectra of (LOWRY, MOUREU, and MACCONKEY), 3167.
Hydroxystyryl methyl ketones (MCGOOKIN and SINCLAIR), 1174.
$C_{10}H_{10}O_4$ Carboxyphenylpropionic acids (TITLEY), 2581.
ω-Hydroxy-4-acetoxyacetophenone (ROBERTSON and ROBINSON), 1465.
$C_{10}H_{10}O_5$ ω-Hydroxy-4-methylcarbonatoacetophenone (ROBERTSON and ROBINSON), 1465.
$C_{10}H_{11}Br$ 4-Methylcinnamyl bromide (BURTON and INGOLD), 915.
$C_{10}H_{12}O$ 4-Methylcinnamyl alcohol (BURTON and INGOLD), 915.
$C_{10}H_{12}O_3$ 3-Methoxy-5-*cyclo*pentane*spirocyclo*penten-1:4-dione (GOSS), 1308.
$C_{10}H_{12}O_4$ 4-Hydroxy-3:5-dimethoxyacetophenone (BRADLEY and ROBINSON), 1564.
5-*cyclo*Pentane*spirodicyclo*pentan-4-ol-3-one-1-carboxylic acid (GOSS), 1309.
$C_{10}H_{13}Br$ *o*-Bromo-*tert.*-butylbenzene (SHOESMITH and MACKIE), 2339.
$C_{10}H_{13}I$ Iodo-*tert.*-butylbenzenes (SHOESMITH and MACKIE), 2338.
$C_{10}H_{14}O_3$ Camphoric anhydride, action of substituted aromatic amines on (SINGH, AHUJA, and LAL), 2410.
Δ^1-*cyclo*Hexenylacetoacetic acid (JUPP, KON, and LOCKTON), 1640.
α-Methyl*cyclo*pentane-1:1-diacetic anhydride (BARDHAN), 2597.
$C_{10}H_{14}O_4$ α-Hydroxy-α-methyl*cyclo*pentane-1:1-diacetolactone, and its salts (BARDHAN), 2598.
$C_{10}H_{16}O$ *l*-Carene oxide (PILLAY and SIMONSEN), 363.
$C_{10}H_{16}O_2$ β-*cyclo*Hexane*spiro*valerolactone, and its silver salt (SIRCAR), 903.
Methyl 8-*cyclo*hexylacrylate (SIRCAR), 55.
Methyl derivative of 2:2:3:3-tetramethyl-[0, 1, 2] *dicyclo*pentan-4-ol-5-one (INGOLD and SHOPPEE), 389.
$C_{10}H_{16}O_3$ Methyl 1-acetyl*cyclo*pentane-1-acetate (BARDHAN), 2601.
Substance, from oxidation of α-phellandrene (HENRY and PAGET), 77.
$C_{10}H_{16}O_4$ *cyclo*Heptylmalonic acid (VOGEL), 2025.
α-Methyl*cyclo*pentane-1:1-diacetic acid, and its silver salt (BARDHAN), 2597.
$C_{10}H_{16}O_5$ Methyl hydrogen γγ-dihydroxy-ααββ-tetramethylglutarate lactone (INGOLD and SHOPPEE), 406.
$C_{10}H_{18}O_2$ *d*-Carene-β-glycol (PILLAY and SIMONSEN), 362.
Methoxy-2:2:3:3-tetramethyl*cyclo*pentanone (INGOLD and SHOPPEE), 402; (SHOPPEE), 1670.
$C_{10}H_{18}O_3$ Ethyl αββ-trimethyl-lævulate (BARDHAN), 2613.
$C_{10}H_{20}O_3$ Ethyl β-hydroxy-αα8-trimethyl-*n*-valerate (BARDHAN), 2615.
n-Octyloxyacetic acid (RULE, HAY, and PAUL), 1357.

10 III

$C_{10}H_2O_3Cl_6$ 5:7-Dichloro-6-hydroxy-2:4-bisdichloromethylene-1:3-benzdioxin (CHATTAWAY and CALVET), 2918.
$C_{10}H_4O_3Cl_6$ 5:7-Dichloro-6-hydroxy-2:4-bistrichloromethyl-1:3-benzdioxin (CHATTAWAY and CALVET), 2918.
$C_{10}H_6N_2Br_4$ 2:3-Di(ω-dibromomethyl)quinoxaline (BENNETT and WILLIS), 1974.
$C_{10}H_6S_2Ni$ Nickel 1:8-dithiolnaphthalene (PRICE and SMILES), 2374.
$C_{10}H_7OBr$ 3-Bromo-β-naphthol (CLEMO and SPENCE), 2819.
$C_{10}H_8O_3Cl_4$ 5-Carboxy-2-methoxy-1-αββ8-tetrachloroethylbenzene (CHATTAWAY and CALVET), 2915.

$C_{10}H_8O_2Br_2$ Dibromo-3-methoxycinnamic acid (H. and W. DAVIES), 604.
$C_{10}H_8O_5S_2$ 1-Sulphinonaphthalene-8-sulphonic acid, and its sodium salt (PRICE and SMILES), 2373.
$C_{10}H_8NCl$ 2-Chloro-6-methylquinoline (HAMER), 210.
$C_{10}H_9OCl$ 3-Chlorostyryl methyl ketone (HEILBRON and HILL), 2868.
$C_{10}H_9O_2N_3$ 3:4-Diformamidobenzyl cyanide (PHILLIPS), 2396.
$C_{10}H_9O_3N$ Indoxylacetic acid (JACKSON and KENNER), 580.
$C_{10}H_9O_3Br$ 6-Bromo-3-methoxycinnamic acid (H. and W. DAVIES), 603.
$C_{10}H_9O_4Cl_3$ 5-Carboxy-2-methoxy-1-$\beta\beta\beta$-trichloro-α-hydroxyethylbenzene (CHATTAWAY and CALVET), 2915.
$C_{10}H_9O_5N$ *p*-Nitro-ω-acetoxyacetophenone (BRADLEY and SCHWARZENBACH), 2907.
$C_{10}H_8NI_2$ 2-Iodoquinoline methiodide (HAMER), 209.
$C_{10}H_{10}O_2Br_2$ Ethyl $\omega\omega$-dibromo-*p*-toluate (TITLEY), 2581.
Safrole *di*bromide (READ and REID), 1490.
$C_{10}H_{10}O_3N_2$ 8-Acetylamino-3-hydroxy-1:4-benz*iso*oxazine (BALABAN), 3070.
Acetylamino-3-hydroxy-1:4-benz*iso*oxazines (NEWBERY and PHILLIPS), 3048.
$C_{10}H_{10}O_5N_2$ *dl*-*p*-Nitrobenzoylalanine, resolution of, and its salts (COLLES and GIBSON), 99.
$C_{10}H_{10}O_6N_2$ 2-Nitro-4-acetamidophenoxyacetic acid (NEWBERY and PHILLIPS), 3049.
$C_{10}H_{11}ON$ 4-Phenyl-2-pyrrolidone (JACKSON and KENNER), 1659.
$C_{10}H_{11}O_2Cl$ Ethyl ω-chloro-*m*-toluate (TITLEY), 2582.
$C_{10}H_{11}O_2Br$ Ethyl ω-bromo-*p*-toluate (TITLEY), 2581.
$C_{10}H_{11}O_5N$ 6-Nitro-3-ethoxy-*p*-toluic acid (CHATTAWAY and CALVET), 1093.
6-Nitro-3-methoxy-4-ethoxybenzaldehyde (BARGER and SILBERSCHMIDT), 2927.
$C_{10}H_{11}O_5N_3$ 2:3-Dinitro-4-acetamidoethylbenzene (BRADY, DAY, and ALLAM), 981.
$C_{10}H_{11}O_6N$ 5-Nitro-2-ethoxymandelic acid (CHATTAWAY and MORRIS), 3244.
$C_{10}H_{12}O_4Ni$ Methyl ethoxynickelosalicylate (DOAK and PACKER), 2763.
$C_{10}H_{12}O_8N_4$ 2:4:6-Trinitro-5-aminoresorcinol diethyl ether (FLÜRSCHEIM and HOLMES), 3045.
$C_{10}H_{13}OCl$ *p*-Chlorophenyl *iso*butyl ether (BRADFIELD and JONES), 3081.
$C_{10}H_{13}O_2N$ γ-Amino-β-phenylbutyric acid, and its hydrobromide (JACKSON and KENNER), 1659.
1-Cyano-2:2:3:3-tetramethyl-[0, 1, 2]-*dicyclo*pentan-4-ol-5-one (INGOLD and SHOPPEE), 388.
$C_{10}H_{13}O_2N_3$ Aminodiacetylphenylenediamines (PHILLIPS), 175.
$C_{10}H_{13}O_3N$ β-Amino-α-hydroxydihydro*iso*safrole, and its hydrochloride (READ and REID), 1491.
Nitro-4-methyl benzyl ethyl ethers (INGOLD and ROTHSTEIN), 1279.
$C_{10}H_{13}O_3Br$ Bromo-α-methyl*cyclo*pentane-1:1-diacetic anhydride (BARDHAN), 2598.
$C_{10}H_{14}O_3N_2$ 2-Nitro-4-amino-*tert.*-butylbenzene (SHOESMITH and MACKIE), 2337.
$C_{10}H_{14}O_6Mo$ Molybdyl bisacetylacetone (MORGAN and CASTELL), 3253.
$C_{10}H_{14}NBr$ 2-Bromo-4-amino-*tert.*-butylbenzene, and its hydrochloride (SHOESMITH and MACKIE), 2339.
$C_{10}H_{14}Cl_2Sn$ Phenyl-*n*-butylstannic chloride (KIPPING), 2371.
$C_{10}H_{15}O_2N$ Ethyl *r*-*cyclo*pentylcyanoacetate (VOGEL), 2021.
β-Hydroxy-β-*p*-methoxyphenyl*iso*propylamines, and their salts (READ and REID), 1489.
α-Methyl*cyclo*pentane-diacetimide (BARDHAN), 2598.
$C_{10}H_{15}O_2Br$ Methyl derivative of 1-bromo-2:2:3:3-tetramethyl-[0, 1, 2]-*dicyclo*pentan-4-ol-5-one (INGOLD and SHOPPEE), 387.

$C_{10}H_{15}O_4S$ *d*-Camphorsulphonic acid, triethylenediaminenickel salt (BUCKNALL and WARDLAW), 2742.

$C_{10}H_{16}O_2Br_2$ Dibromo-5-methoxy-2:2:3:3-tetramethyl*cyclo*pentanone (SHOPPEE), 2363.

$C_{10}H_{17}ON_3$ *cyclo*Hexylideneacetone semicarbazone (DICKINS, HUGH, and KON), 1636

$C_{10}H_{17}OCl$ Hydroxychlorocarane (PILLAY and SIMONSEN), 364.

$C_{10}H_{17}OAs$ Benzyltrimethylarsonium hydroxide, picrate of (INGOLD, SHAW, and WILSON), 1283.

$C_{10}H_{17}OP$ Benzyltrimethylphosphonium hydroxide, picrate of (INGOLD, SHAW, and WILSON), 1283.

$C_{10}H_{17}O_2N_3$ 3:3:4:4-Tetramethyl*cyclo*pentane-1:2-dione semicarbazone (INGOLD and SHOPPEE), 396.

$C_{10}H_{17}O_3N$ α-Methyl-Δ^1-*cyclo*pentenylacetone semicarbazone (BARDHAN), 2604.

α-Methyl*cyclo*pentylideneacetone semicarbazone (BARDHAN), 2603.

$C_{10}H_{17}O_3N_3$ 1-Acetyl*cyclo*pentane-1-acetic acid semicarbazone (BARDHAN), 2601.

Ethyl *iso*propylideneacetoacetate semicarbazone (JUPP, KON, and LOCKTON), 1642.

$C_{10}H_{19}ON_3$ Tetramethyl*cyclo*pentanone semicarbazones (INGOLD and SHOPPEE), 398.

$C_{10}H_{19}O_3Tl$ Ethyl thallium diethylacetoacetate (MENZIES, SIDGWICK, CUTCLIFFE, and FOX), 1290.

$C_{10}H_{20}Cl_2Te$ 1-ε-Chloroamyl*cyclo*telluripentane 1-chloride (MORGAN and BURGESS), 325.

$C_{10}H_{20}Br_2Te$ 1-ε-Bromoamyl*cyclo*telluripentane 1-bromide (MORGAN and BURGESS), 326.

$C_{10}H_{20}I_2Te$ 1-ε-Iodoamyl*cyclo*telluripentane 1-iodide (MORGAN and BURGESS), 328.

$C_{10}H_{22}O_2S$ Ethyl-*n*-octylsulphone (FENTON and INGOLD), 3129.

10 IV

$C_{10}H_5O_2NCl_4$ 6-Amino-2:4-bisdichloromethylene-1:3-benzdioxin (CHATTAWAY and CALVET), 1091.

$C_{10}H_5O_6N_2Cl_3$ 6:8-Dinitrodichloromethylchloromethylene-1:3-benzdioxin (CHATTAWAY and MORRIS), 3246.

$C_{10}H_6O_4NCl_3$ 6-Nitrodichloromethylchloromethylene-1:3-benzdioxin (CHATTAWAY and MORRIS), 3243.

$C_{10}H_6O_6N_2Cl_4$ 6:8-Dinitro-2:4-bisdichloromethyl-1:3-benzdioxin (CHATTAWAY and MORRIS), 2345.

$C_{10}H_7O_2Cl_4Br$ 6-Bromo-2:4-bisdichloromethyl-1:3-benzdioxin (CHATTAWAY and MORRIS), 3245.

$C_{10}H_7O_3IS$ 1-Iodonaphthalene-2-sulphinic acid (BARBER and SMILES), 1145.

$C_{10}H_7O_3IS$ 1-Iodonaphthalene-2-sulphonic acid (BARBER and SMILES), 1144.

$C_{10}H_7O_4NCl_4$ 6-Nitro-2:4-bisdichloromethyl-1:3-benzdioxin (CHATTAWAY and MORRIS), 3243.

$C_{10}H_7O_4Cl_5S$ 2:4-Bisdichloromethyl-1:3-benzdioxin-6-sulphonyl chloride (CHATTAWAY and MORRIS), 3246.

$C_{10}H_8ON_2Cl_6$ Chloral α-acetyl-2:4:6-trichlorophenylhydrazone (CHATTAWAY and DALDY), 2759.

$C_{10}H_8O_2N_2Cl_4$ Ethyl glyoxylate ω-chloro-2:4:6-trichlorophenylhydrazone (CHATTAWAY and DALDY), 2761.

$C_{10}H_8O_2N_2Br_4$ Ethyl glyoxylate ω-bromo-2:4:6-tribromophenylhydrazone (CHATTAWAY and DALDY), 2762.

$C_{10}H_8O_5Cl_4S$ 2:4-Bisdichloromethyl-1:3-benzdioxin-6-sulphonic acid, and its ammonium salt (CHATTAWAY and MORRIS), 3245.

$C_{10}H_9O_2NCl_4$ 6-Amino-2:4-bisdichloromethyl-1:3-benzdioxin, and its hydrochloride (CHATTAWAY and MORRIS), 3244.

$C_{10}H_9O_2N_3Cl_2$ Ethyl glyoxylate 2:4:6-trichlorophenylhydrazone (CHATTAWAY and DALDY), 2759.

$C_{10}H_9O_2N_2Br_3$ Ethylglyoxalate 2:4:6-tribromophenylhydrazone (CHATTAWAY and DALDY), 2762.

$C_{10}H_9O_2NI_2$ 3:5-Di-iodo-4-acetamidophenyl acetate (HUNTER and BARNES), 2067.

$C_{10}H_{10}ON_2S$ 1-Acetamido-3-methylbenzthiazole (HUNTER and STYLES), 3022.

1-Imino-2-acetyl-3-methyl-1:2-dihydrobenzthiazole (HUNTER and STYLES), 3022.

$C_{10}H_{10}O_2N_2S$ Benziminazolyl-2-α-thiolpropionic acid (STEPHEN and WILSON), 1420.

$C_{10}H_{10}O_3NBr$ 5-Bromomethylacetylanthranilic acid (HEILBRON, HOLT, and KITCHEN), 941.

$C_{10}H_{11}ONCl_2$ Acetyldichloro-*o*-xylidines (HINKEL, AYLING, and BEVAN), 1877.

$C_{10}H_{11}O_3NS$ β-Cyanoethyl toluene-*p*-sulphonate (CLEMO and WATSON), 726.

$C_{10}H_{11}O_4N_2As$ 3 5-Diacetamido-2-hydroxyphenylarsenoxide (NEWBERY and PHILLIPS), 2378.

$C_{10}H_{11}O_6N_2As$ Acetamidohydroxy-1:4-benz*iso*oxazine-6-arsinic acid (NEWBERY, PHILLIPS, and STICKINGS), 3058.

8-Acetamido-3-hydroxy-1:4-benz*iso*oxazinearsinic acids (BALABAN), 3069.

$C_{10}H_{12}O_2NBr$ 2-Bromo-4-nitro-*tert.*-butylbenzene (SHOESMITH and MACKIE), 2339.

$C_{10}H_{12}O_5NAs$ 3-Hydroxy-2-ethyl-1:4-benz*iso*oxazine-6-arsinic acid (NEWBERY, PHILLIPS, and STICKINGS), 3063.

$C_{10}H_{12}O_6N_2As$ 8-Glycylamino-3-hydroxy-1:4-benz*iso*oxazine-6-arsinic acid (NEWBERY, PHILLIPS, and STICKINGS), 3060.

$C_{10}H_{12}O_7NAs$ 2-Acetamidophenoxyacetic acid 4-arsinic acid (NEWBERY, PHILLIPS, and STICKINGS), 3054.

$C_{10}H_{13}ONS$ 2:4-Dimethylthiolacetanilide (HODGSON and HANDLEY), 164.

$C_{10}H_{13}ON_2Cl$ Chloroacetamidodimethylanilines (CLEMO and SMITH), 2420.

$C_{10}H_{13}ON_2Br$ 4-Bromo-2-acetamidodimethylaniline (CLEMO and SMITH), 2421.

$C_{10}H_{13}O_5N_2As$ 3:5-Diacetamido-4-hydrophenylarsinous acid (NEWBERY and PHILLIPS), 2378.

$C_{10}H_{13}O_6N_2As$ 2-Acetamidophenoxyacetamide 4-arsinic acid (NEWBERY, PHILLIPS, and STICKINGS), 3055.

2:4-Diacetamido-3-hydroxyphenylarsinic acid (BALABAN), 812.

3:5-Diacetamido-2-hydroxyphenylarsinic acid (NEWBERY and PHILLIPS), 2376.

8-β-Hydroxyethylamino-3-hydroxy-1:4-benz*iso*oxazine-6-arsinic acid (NEWBERY, PHILLIPS, and STICKINGS), 3062.

$C_{10}H_{13}O_7N_2As$ 4-ω-Hydroxyacetamido-2-acetamido-3-hydroxyphenylarsinic acid (BALABAN), 3070

$C_{10}H_{16}ONI$ *p*-Dimethylaminobenzyl methiodide (CLEMO and SMITH), 2425.

$C_{10}H_{16}O_3NAs$ *p*-Nitrobenzyltrimethylarsonium hydroxide, picrate of (INGOLD, SHAW, and WILSON), 1285.

$C_{10}H_{16}O_2NP$ Nitrobenzyltrimethylphosphonium hydroxides, picrates of (INGOLD, SHAW, and WILSON), 1284.

10 V

$C_{10}H_6O_2NCl_6Br$ 7-Bromo-6-amino-2:4-bistrichloromethyl-1:3-benzdioxin (CHATTAWAY and CALVET), 1091.

$C_{10}H_6O_2ClIS$ 1-Iodonaphthalene-2-sulphonyl chloride (BARBER and SMILES), 1145.

$C_{10}H_7O_2N_3Cl_4Br_2$ 2:4-Bisdichloromethyl-1:3-benzdioxin-6-diazonium perbromide (CHATTAWAY and MORRIS), 3245.

$C_{10}H_8O_2N_2ClBr_2$ Ethyl glyoxylate ω-chloro-2:4:6-tribromophenylhydrazone (CHATTAWAY and DALDY), 2762.

$C_{10}H_8O_2N_2Cl_3Br$ Ethyl glyoxylate ω-bromo-2:4:6-trichlorophenylhydrazone (CHATTAWAY and DALDY), 2761.

$C_{10}H_9O_3NClBr$ Chlorobromoacetamidophenyl acetates (HUNTER and BARNES), 2060.

$C_{10}H_9O_3NClI$ Chloroiodoacetamidophenyl acetates (HUNTER and BARNES), 2061.

$C_{10}H_9O_3NBrI$ Bromoiodoacetamidophenyl acetates (HUNTER and BARNES), 2062.

$C_{10}H_9O_4NCl_4S$ 2:4-Bisdichloromethyl-1:3-benzdioxin-6-sulphonamide (CHATTAWAY and MORRIS), 3246.

$C_{10}H_{10}ON_2Br_4S$ 1-Acetamido-3-methylbenzthiazole tetrabromide (HUNTER and STYLES), 3022.

$C_{10}H_{10}ON_2Br_6S$ 1-Acetamido-3-methylbenzthiazole hexabromide (HUNTER and STYLES), 3022.

$C_{10}H_{11}ON_2Br_3S$ 1-Imino-2-acetyl-3-methyl-1:2-dihydrobenzthiazole tribromide (HUNTER and STYLES), 3022.

C_{11} Group.

$C_{11}H_{10}O_3$ 1-Ketohydrindene-3-acetic acid (JACKSON and KENNER), 577.

$C_{11}H_{10}O_4$ 3:4-Dihydrocoumarin-4-acetic acid (SESHADRI), 169.

$C_{11}H_{10}O_6$ *p*-Carboxybenzylmalonic acid (TITLEY), 2581.

$C_{11}H_{12}O$ 1-Keto-2-methyltetrahydronaphthalene (TITLEY), 2578.

$C_{11}H_{12}O_2$ 4-Hydroxystyryl ethyl ketone (MCGOOKIN and SINCLAIR), 1173.

$C_{11}H_{12}O_4$ β-Carboxyphenyl*iso*butyric acids (TITLEY), 2577.

Phenylene-1-acetic-α-propionic acids (TITLEY), 2580.

$C_{11}H_{12}O_5$ 2:5-Dimethoxyphenylpyruvic acid (GULLAND and VIRDEN), 1482.

β-*o*-Hydroxyphenylglutaric acid (SESHADRI), 169.

$C_{11}H_{12}N_2$ 3:2:5:6-Tetrahydro-4-carboline (ASHLEY and ROBINSON), 1376.

$C_{11}H_{13}N$ Tetrahydropentindole (PLANT and RIPPON), 1911.

$C_{11}H_{14}O_2$ *o-tert.*-Butylbenzoic acid (SHOESMITH and MACKIE), 2339.

$C_{11}H_{14}O_3$ 3:4-Dimethoxy-6-ethylbenzaldehyde (BARGER and SILBERSCHMIDT), 2925.

6-Methoxy-3-ethylphenylacetic acid, and its sodium salt (GULLAND and VIRDEN), 931.

$C_{11}H_{14}O_4$ 3:4-Dimethoxy-6-ethylbenzoic acid (BARGER and SILBERSCHMIDT), 2925.

Methyl 5-*cyclo*pentane*spirodicyclo*pentan-4-ol-3-one-1-carboxylate (GOSS), 1309.

ω:3:5-Trimethoxyacetophenone (ROBERTSON, ROBINSON, and SUGIURA), 1535.

$C_{11}H_{14}O_5$ 4-Hydroxy-ω:3:5-trimethoxyacetophenone (BRADLEY and ROBINSON), 1567.

ω-Hydroxy-3:4:5-trimethoxyacetophenone (BRADLEY and ROBINSON), 1551.

$C_{11}H_{14}N_2$ 4-Aminomethyl-1-methyl-3:4-dihydro*iso*quinoline, and its hydrochloride (JACKSON and KENNER), 1659.

$C_{11}H_{16}O_2$ Acetyl derivative of 2:2:3:3-tetramethyl-[0, 1, 2]-*dicyclo*pentan-4-ol-5-one (INGOLD and SHOPPEE), 389.

$C_{11}H_{16}N_2$ α- and β-2:3:7-Trimethyl-1:2:3:4-tetrahydroquinoxalines, resolution of and their salts (GIBSON, NUTLAND, and SIMONSEN), 108.

$C_{11}H_{18}O_2$ 5-Acetoxy-2:2:3:3-tetramethyl*cyclo*pentanone (INGOLD and SHOPPEE), 397.

$C_{11}H_{18}O_4$ β-*cyclo*Hexylglutaric acid, and its silver salt (SIRCAR), 56.

$H_{18}N$ KENNER), 1659.

$C_{11}H_{20}O_2$ Allyl octoate (DEULOFEU), 528.

$C_{11}H_{20}O_6$ Propyl tartrates, rotatory dispersion of (AUSTIN), 1832.

11 III

$C_{11}H_9OBr$ 3-Bromo-2-methoxynaphthalene (CLEMO and SPENCE), 2818.
$C_{11}H_9OI$ 3-Iodo-2-methoxynaphthalene (CLEMO and SPENCE), 2819.
$C_{11}H_9O_6N$ 6-Nitro-3:4-dihydrocoumarin-4-acetic acid, and its disilver salt (SESHADRI), 171.
$C_{11}H_{10}O_2Cl_2$ β-Phenylglutaryl chloride (JACKSON and KENNER), 578.
$C_{11}H_{11}ON$ 1:6-Dimethyl-2-quinolone (HAMER), 209.
2-Methoxy-3-naphthylamine (CLEMO and SPENCE), 2818.
$C_{11}H_{11}O_3N$ 7:8-Dimethoxycarbostyril (GULLAND and VIRDEN), 932.
O-Methylindoxylacetic acid (JACKSON and KENNER), 580.
$C_{11}H_{11}O_3Cl$ Ethyl *p*-chlorobenzoylacetate (BURTON and INGOLD), 920.
$C_{11}H_{11}O_5N$ 5-Nitro-2-ethoxy-*p*-tolylglyoxylic acid (CHATTAWAY and CALVET), 1093.
$C_{11}H_{11}O_5Cl$ *O*-Acetylsyringoyl chloride (BRADLEY and ROBINSON), 1551.
$C_{11}H_{11}O_6N$ *trans*-2-Nitro-3:4-dimethoxycinnamic acid (GULLAND and VIRDEN), 932.
$C_{11}H_{11}NI_2$ 2-Iodo-6-methylquinoline methiodide (HAMER), 210.
2-Iodoquinoline ethiodide (HAMER), 209.
$C_{11}H_{12}O_2N_2$ 1-2-Pyrrolidone-5-carboxyanilide (GRAY), 1265.
$C_{11}H_{13}O_4N$ 2-Amino-3:4-dimethoxycinnamic acid, and its hydrochloride (GULLAND and VIRDEN), 932.
$C_{11}H_{13}O_5N$ Methylopianic oximes (BRADY, BAKER, GOLDSTEIN, and HARRIS), 536.
$C_{11}H_{13}O_6N$ Dimethyl hydrogen 3-amino-1-methyl*dicyclo*pentene-2:4:5-tricarboxylate (GOSS and INGOLD), 1275.
5-Nitro-2-ethoxy-4-methylmandelic acid (CHATTAWAY and CALVET), 1093.
$C_{11}H_{13}N_2I$ Dimethylquinoxaline methiodide (BENNETT and WILLIS), 1975.
$C_{11}H_{14}N_2S$ 1-*n*-Propylamino-3-methylbenzthiazole (HUNTER and STYLES), 3026.
$C_{11}H_{15}ON$ γ-Imino-γ-ethoxy-α-phenylpropane, hydrochloride of (CLEMO and WATSON), 728.
$C_{11}H_{15}O_2N_3$ 6-Methoxy-3-ethylbenzaldehyde semicarbazone (GULLAND and VIRDEN), 930.
$C_{11}H_{15}O_3Cl$ Acetyl derivative of 1-chloro-2:2:3:3-tetramethyl-[0, 1, 2]-*dicyclo*pentan-4-ol-5-one (INGOLD and SHOPPEE), 403.
$C_{11}H_{16}O_3N_4$ β-Phenylglutardihydrazide (JACKSON and KENNER), 1658.
$C_{11}H_{16}O_4N_4$ 3-Methyl-5-pyrazolone-1-carboxy-α-carbethoxy*iso*propylidenehydrazide (MUNRO and WILSON), 1260.
$C_{11}H_{16}N_2S$ *s*-*o*-Tolyl-*n*-propylthiocarbamide (HUNTER and STYLES), 3026.
$C_{11}H_{17}O_2N$ Ethyl *r*-*cyclo*hexylcyanoacetate (VOGEL), 2023.
$C_{11}H_{17}O_3N_3$ Δ^1-*cyclo*Hexenylacetoacetic acid semicarbazone (JUPP, KON, and LOCKTON), 1640.
$C_{11}H_{17}O_5Br$ Ethyl α-bromo-α-acetylglutarate (CLEMO and WELCH), 2626.
$C_{11}H_{19}ON_3$ *l*-Carene oxide semicarbazone (PILLAY and SIMONSEN), 363.
$C_{11}H_{19}O_3N$ 5-Acetoxy-2:2:3:3-tetramethyl*cyclo*pentaneoxime (INGOLD and SHOPPEE), 1871.
$C_{11}H_{19}O_3N_3$ Methyl 1-acetyl*cyclo*pentane-1-acetate semicarbazone (BARDHAN), 2601.
$C_{11}H_{19}O_4N$ Ethyl α-(α′-aminoethylidene)glutarate (CLEMO and WILSON), 2627.
$C_{11}H_{20}O_2N_2$ β-*cyclo*Hexylglutardiamide (SIRCAR), 56.
$C_{11}H_{21}ON$ Acetyltetramethyl*cyclo*pentylamines (INGOLD and SHOPPEE), 394, 399; (SHOPPEE), 1670.

11 IV

$C_{11}H_7O_4NCl_6$ 6-Nitro-7-methyl-2:4-bistrichloromethyl-1:3-benzdioxin (CHATTAWAY and CALVET), 1092.

$C_{11}H_7O_8N_4Cl$ Ethyl 2:4-trinitrophenylchlorocyanoacetate (FAIRBOURNE and FAWSON), 1080.

$C_{11}H_{10}O_5Cl_4S$ Methyl 2:4-bisdichloromethyl-1:3-benzdioxin-6-sulphonate (CHATTAWAY and MORRIS), 3245.

$C_{11}H_{10}O_7N_3Cl$ Ethyl 2:4-dinitrophenylchloromalonamate (FAIRBOURNE and FAWSON), 1078.

$C_{11}H_{11}O_2N_2Br$ 1-2-Pyrrolidone-5-carboxy-*p*-bromoanilide (GRAY), 1266.

$C_{11}H_{12}ON_2S$ Acetyl derivative of 1-methylamino-3-methylbenzthiazole (HUNTER and STYLES), 3025.

$C_{11}H_{12}O_2N_2S$ Benziminazolyl-2-α-thiol-*n*-butyric acid (STEPHEN and WILSON), 1419.

$C_{11}H_{12}O_3NCl$ Diacetyl derivative of 3-chloro-2-aminoanisole (HODGSON and KERSHAW), 192.

$C_{11}H_{13}O_5NHs$ 3-Acetoxymercuriaceto-*p*-toluidide (BELL), 2778.

$C_{11}H_{13}N_2BrS$ 5-Bromo-1-*n*-propylamino-3-methylbenzthiazole (HUNTER and STYLES), 3026.

$C_{11}H_{14}N_2Br_2S$ 5-Bromo-1-*n*-propylamino-3-methylbenzthiazole hydrobromide (HUNTER and STYLES), 3026.

$C_{11}H_{14}N_2Br_4S$ 1-*n*-Propylamino-3-methylbenzthiazole tetrabromide (HUNTER and STYLES), 3026.

$C_{11}H_{15}O_3NS_2$ β-Dithian monoxide *S*-*p*-toluenesulphonylimine (BELL and BENNETT), 92.

$C_{11}H_{15}N_2BrS$ *s*-5-Bromo-*o*-tolyl-*n*-propylthiocarbamide (HUNTER and STYLES), 3026.

1-*n*-Propylamino-3-methylbenzthiazole hydrobromide (HUNTER and STYLES), 3026.

$C_{11}H_{17}NCl_2As$ *l*-α-Phenylethylaminopropyldichloroarsine hydrochloride (GOUGH and KING), 2443.

$C_{11}H_{22}O_5NAs$ γ-3-Carbethoxypiperidinopropylarsinic acid (GOUGH and KING), 2446.

$C_{11}H_{24}O_3NAs$ γ-2:2:6-Trimethylpiperidinopropylarsinic acid (GOUGH and KING), 2445.

$C_{11}H_{24}O_4NAs$ γ-4-Hydroxy-2:2:6-trimethylpiperidinopropylarsinic acid (GOUGH and KING), 2444.

11 V

$C_{11}H_{14}O_7N_2ClAs$ 3-ω-Chlorocarbethoxyamino-5-acetamido-4-hydroxyphenylarsinic acid (NEWBERY, PHILLIPS, and STICKINGS), 3064.

C_{12} Group.

$C_{12}H_7Cl_3$ Trichlorodiphenyls (HINKEL and HEY), 2791.

$C_{12}H_8S_2$ Diphenylene 2:2′-disulphide (BARBER and SMILES), 1146.

$C_{12}H_{10}O_2$ 2-Phenyl-6-methyl-4-pyrone, and its salts (GIBSON and SIMONSEN), 2307.

$C_{12}H_{10}O_3$ Methoxynaphthoic acids (BRETSCHER, RULE, and SPENCE), 1500.

$C_{12}H_{10}Cl_2$ 3:5-Dichloro-1-phenyl-$\Delta^{2:4}$-*cyclo*hexadiene (HINKEL and HEY), 2789.

$C_{12}H_{10}S_2$ 2:2′-Dithioldiphenyl (BARBER and SMILES), 1146.

$C_{12}H_{12}O_3$ Methyl 1-ketohydrindene-3-acetate (JACKSON and KENNER), 578.

$C_{12}H_{12}O_4$ β-*p*-Methoxyphenylglutaric anhydride (JACKSON and KENNER), 1660.

7-Methyl-3:4-dihydrocoumarin-4-acetic acid (SESHADRI), 170.

$C_{12}H_{12}O_5$ 3:4-Dimethoxy-α-methylhomophthalic anhydride (KOEPFLI and PERKIN), 2398.

$C_{12}H_{12}O_6$ Diacetylgallacetophenone (PERKIN and STOREY), 242.

3:4-Dimethoxybenzylidenemalonic acid (JACKSON and KENNER), 1661.

$C_{12}H_{12}S_2$ 1:8-Dimethyldithiolnaphthalene (PRICE and SMILES), 2374.

$C_{12}H_{14}O_2$ Hydroxystyryl propyl ketones (McGookin and Sinclair), 1175.
$C_{12}H_{14}O_3$ 5:6-Dimethoxy-3-methyl-1-hydrindone (Koepfli and Perkin), 2996.
Methoxystyryl ethyl ketones, hydroxy- (McGookin and Sinclair), 1174.
$C_{12}H_{14}O_4$ γ-*o*-Carboxyphenyl-α-methylbutyric acid (Titley), 2578.
6-Methoxy-3-ethylphenylpyruvic acid, and its sodium salt (Gulland and Virden), 930.
Methyl carboxyphenylpropionates (Titley), 2581.
Methyl phenylenediacetates (Titley), 2579.
β-Veratrylcrotonic acid (Koepfli and Perkin), 2996.
$C_{12}H_{14}O_5$ β-*p*-Methoxyphenylglutaric acid (Jackson and Kenner), 1660.
β-*p*-Methyl-*o*-hydroxyphenylglutaric acid (Seshadri), 170.
$C_{12}H_{14}O_7$ Methyl 5-methyl*dicyclo*penten-3-ol-1:2:4-tricarboxylate (Goss and Ingold), 1272.
$C_{12}H_{15}N$ Hexahydroquinidenes (Perkin and Plant), 644.
8-Methyltetrahydropentindole, and its salts (Plant and Rippon), 1912.
$C_{12}H_{16}O_3$ Butyl *l*-mandelates, rotatory dispersion of (Wood, Chrisman, and Nicholas), 2180.
$C_{12}H_{16}O_4$ 3:4-Dimethoxy-6-ethylphenylacetic acid (Barger and Silberschmidt), 2926.
β-Veratrylbutyric acid (Koepfli and Perkin), 2996.
$C_{12}H_{18}O_2$ *cyclo*Hexane*spiro*-4-methyl*cyclo*hexane-3:5-dione (Dickins, Hugh, and Kon), 1636.
$C_{12}H_{18}O_4$ Ethyl ester of α-hydroxy-α-methyl*cyclo*pentane-1:1-diacetolactone (Bardhan), 2598.
$C_{12}H_{18}O_7$ α-Phenylglucoside hydrate (Hickinbottom), 3147.
$C_{12}H_{18}O_8$ Ethyl diacetyltartrate (Findlay and Campbell), 1772.
Methyl dipropionyl tartrate (Findlay and Campbell), 1773.
$C_{12}H_{20}O_4$ Ethyl 1-carboxy*cyclo*pentane-1-acetate (Vogel), 2022.
$C_{12}H_{20}O_5$ Ethyl α-*iso*propylacetonedicarboxylate (Hariharan, Menon, and Simonsen), 435.
$C_{12}H_{22}O_5$ Ethyl β-hydroxy-α-*iso*propylglutarate (Hariharan, Menon, and Simonsen), 436.
$C_{12}H_{22}O_6$ Butyl tartrates, rotatory dispersion of (Austin), 1833.
$C_{12}H_{22}O_8$ Irigenin trimethyl ether (Baker), 1028.
$C_{12}H_{24}O_2$ Lauric acid, potassium salt, hydrolysis in solutions of (McBain and Eaton), 2166.
$C_{12}H_{24}O_3$ 11-Hydroxydodecoic acid, and its magnesium salt (Bhattacharya, Saletore, and Simonsen), 2679.
$C_{12}H_{26}N_2$ Tetraethylpiperazine, salts of (Gough and King), 2438.

12 III

$C_{12}H_6O_4Cl_6$ 5:7-Dichloro-6-acetoxy-2:4-bistrichloromethyl-1:3-benzdioxin (Chattaway and Calvet), 2918.
$C_{12}H_7N_2Cl$ 2-Chlorophenazine (McCombie, Scarborough, and Waters), 356.
$C_{12}H_7N_2Br$ 2-Bromophenazine (McCombie, Scarborough, and Waters), 356.
$C_{12}H_8OBr_2$ 4:5-Dibromo-3-hydroxydiphenyl (Hinkel and Hey), 1203.
$C_{12}H_8OS$ Phenoxthionine (Drew), 519.
$C_{12}H_8OSe$ Phenoxselenine (Drew), 521.
$C_{12}H_8OTe$ Phenoxtellurine, determination of, in tellurylium compounds (Drew), 509.
$C_{12}H_8O_2S$ Phenoxthionine oxide (Drew), 520.
$C_{12}H_8O_2Se$ Phenoxselenine oxide (Drew), 522.
$C_{12}H_8O_2S_2$ Diphenylene 2:2′-disulphoxide (Barber and Smiles), 1146.

$C_{12}H_8O_2S$ Phenoxthionine dioxide (DREW), 520.
$C_{12}H_8O_8N_4$ 3:5:4′-Trinitro-2-aminodiphenyl (BELL), 2775.
$C_{12}H_8N_2Cl_2$ 4:4′-Dichloroazobenzene (BURNS, MCCOMBIE, and SCARBOROUGH), 2933.
$C_{12}H_8N_2Br_2$ 3:5-Dibromoazobenzene (BURNS, MCCOMBIE, and SCARBOROUGH), 2936.
$C_{12}H_8I_2S_2$ Di-2-iodophenyl disulphide (BARBER and SMILES), 1144.
$C_{12}H_9OBr$ 5-Bromo-3-hydroxydiphenyl (HINKEL and HEY), 1203.
$C_{12}H_9O_4N$ 3:4-Dihydrocoumarin-4-cyanoacetic acid (SESHADRI), 169.
$C_{12}H_9O_4N_3$ Dinitroaminodiphenyls (BELL), 2774.
Ethyl *n*-nitrophenyldicyanoacetate (FLÜRSCHEIM and HOLMES), 2240.
$C_{12}H_9O_5N_3$ 6-Nitro-3:4-dihydrocoumarin-4-cyanoacetamide (SESHADRI), 170.
$C_{12}H_9NCl_2$ Dichloroaminodiphenyls (HINKEL and HEY), 2790.
$C_{12}H_9N_3Br_2$ 3:5-Dibromo-4-aminoazobenzene (BURNS, MCCOMBIE, and SCARBOROUGH), 2935.
$C_{12}H_{10}O_2N_2$ Ethyl phenyldicyanoacetate (FLÜRSCHEIM and HOLMES), 2237.
5-Nitro-2-aminodiphenyl (BELL), 2774.
$C_{12}H_{10}O_2S$ Diphenylsulphone, parachor for (FREIMAN and SUGDEN), 268.
$C_{12}H_{10}O_3N_2$ 3:4-Dihydrocoumarin-4-cyanoacetamide (SESHADRI), 168.
$C_{12}H_{10}O_3Se$ Phenoxselenine dihydroxide (DREW), 522.
$C_{12}H_{10}O_4S_2$ Diphenyl-4:4′-disulphinic acid (BARBER and SMILES), 1148.
$C_{12}H_{10}O_5N_2$ ω-Diazo-3:4-diacetoxyacetophenone (BRADLEY and SCHWARZENBACH), 2907.
$C_{12}H_{10}NBr$ 5-Bromo-3-aminodiphenyl (HINKEL and HEY), 1839.
$C_{12}H_{10}N_2Br_2$ 2:6-Dibromobenzidine (BURNS, MCCOMBIE, and SCARBOROUGH), 2936.
5:4′-Dibromo-3:4-diaminodiphenyl (HINKEL and HEY), 1840.
3:5-Dibromohydrazobenzene (BURNS, MCCOMBIE, and SCARBOROUGH), 2936.
$C_{12}H_{10}N_2Cl$ 3-Chloro-4-aminoazobenzene (BURNS, MCCOMBIE, and SCARBOROUGH), 2935.
$C_{12}H_{11}OBr$ 5-Bromo-1-phenyl-Δ^4-*cyclo*hexen-3-one (HINKEL and HEY), 1202.
$C_{12}H_{11}OBr_3$ 4:5:5-Tribromo-1-phenyl*cyclo*hexan-3-one (HINKEL and HEY), 1202.
$C_{12}H_{11}O_2N_3$ 3-Nitrobenzidine (LE FÈVRE and TURNER), 253.
$C_{12}H_{11}O_3N_3$ 6-Amino-3:4-dihydrocoumarin-4-cyanoacetamide (SESHADRI), 171.
$C_{12}H_{11}O_4N$ *iso*Nitroso-derivative of methyl 1-ketohydrindene-3-acetate (JACKSON and KENNER), 578.
$C_{12}H_{11}O_5Br$ 6-Bromo-3:4-dimethoxy-α-methylhomophthalic anhydride (KOEPFLI and PERKIN), 2998.
$C_{12}H_{11}O_5Cl$ ω-Chloro-3:4-diacetoxyacetophenone (BRADLEY and SCHWARZENBACH), 2908.
$C_{12}H_{11}NAs_2$ 4-Aminoarsenobenzene, and its hydrochloride (NEWBERY and PHILLIPS), 120.
$C_{12}H_{11}NSe$ 4-Aminodiphenyl selenide, and its hydrochloride (GAYTHWAITE, KENYON, and PHILLIPS), 2290.
$C_{12}H_{11}N_3Cl$ 2-Chlorobenzidine (BURNS, MCCOMBIE, and SCARBOROUGH), 2935.
$C_{12}H_{11}N_2Br$ 4′-Bromo-2-aminodiphenylamine (MCCOMBIE, SCARBOROUGH, and WATERS), 356.
$C_{12}H_{12}O_5N_2$ 6-Amino-3:4-dihydrocoumarin-4-carbamylacetic acid, and its hydrochloride (SESHADRI), 172.
$C_{12}H_{13}O_2N$ Acetyl derivative of 4-phenyl-2-pyrrolidone (JACKSON and KENNER), 1659.
$C_{12}H_{13}O_3N_3$ 1-Ketohydrindene-3-acetic acid semicarbazone (JACKSON and KENNER), 578.

$C_{12}H_{13}O_2Br$ 4-Bromo-6:7-dimethoxy-3-methyl-1-hydrindone (KOEPFLI and PERKIN), 2997.

$C_{12}H_{13}O_4N$ *iso*Nitroso-5:6-dimethoxy-3-methyl-1-hydriadone (KOEPFLI and PERKIN), 2997.

$C_{12}H_{14}O_3N_2$ $\gamma\delta$-Diketohexoic acid γ-phenylhydrazone (CLEMO and WELCH), 2627.

$C_{12}H_{14}O_5N_2$ Ethyl *p*-nitrobenzoylalanines (COLLES and GIBSON), 107.

$C_{12}H_{15}ON$ Δ^{α}-Hexenanilide (GOLDBERG and LINSTEAD), 2351.

Methylpentenoic anilides (GOLDBERG and LINSTEAD), 2353.

$C_{12}H_{15}O_2Tl$ Thallium dimethyl benzoylacetone (MENZIES, SIDGWICK, CUTCLIFFE, and FOX), 1290.

$C_{12}H_{15}O_3N$ 5:6-Dimethoxy-3-methyl-1-hydrindone oxime (KOEPFLI and PERKIN), 2997.

$C_{12}H_{15}O_3Cl_3$ Parabutylchlorals (CHATTAWAY and KELLETT), 2712.

$C_{12}H_{15}O_4Br$ 6-Bromo-β-veratrylbutyric acid (KOEPFLI and PERKIN), 2997.

$C_{12}H_{15}O_6N$ Methyl 3-amino-1-methyl*dicyclo*pentene-2:4:5-tricarboxylate (GOSS and INGOLD), 1274.

Methyl 3-methyl-1:2-dicarbomethoxy*cyclo*propane-3-cyanoacetate (GOSS and INGOLD), 1273.

$C_{12}H_{16}O_5S$ β-Carbethoxyethyl toluene-*p*-sulphonate (CLEMO and WATSON), 727.

$C_{12}H_{17}O_2N$ Ethyl *cyclo*heptylidenecyanoacetate (VOGEL), 2024.

$C_{12}H_{17}O_2N_3$ Aldehydomethyl*iso*propylphenol semicarbazones (BELL and HENRY), 2219. 2221.

$C_{12}H_{17}O_4N_3$ ω:3:5-Trimethoxyacetophenone semicarbazone (ROBERTSON, ROBINSON, and SUGUIRA), 1536.

$C_{12}H_{18}O_2N_6$ Thymoquinone disemicarbazone (HENRY and PAGET), 80.

$C_{12}H_{18}O_3N_4$ β-*p*-Methoxyphenylglutaric dihydrazide (JACKSON and KENNER), 1660.

$C_{12}H_{18}O_6Mo$ Molybdyl bispropionylacetone (MORGAN and CASTELL), 3254.

$C_{12}H_{19}O_2N$ Ethyl *r-cyclo*heptylcyanoacetate (VOGEL), 2025.

$C_{12}H_{21}O_4Cl$ Ethyl β-chloro-*a-iso*propylglutarate (HARIHARAN, MENON, and SIMONSEN), 436.

12 IV

$C_{12}H_6O_2NCl_3$ 2:3:5-Trichloro-4′-nitrodiphenyl (HINKEL and HEY), 2791.

$C_{12}H_6O_2N_2Cl_4$ Tetrachlorodihydroxyazobenzenes (HUNTER and BARNES), 2054.

$C_{12}H_6O_2N_2I_4$ 3:5:3′:5-Tetraiodo-2:2′-dihydroxyazobenzene (HUNTER and BARNES), 2058.

$C_{12}H_6O_4Cl_4S_2$ 4:4′-Dichlorodiphenyl-3:3′-disulphonyl chloride (BARBER and SMILES), 1147.

$C_{12}H_7O_2NCl_2$ Dichloronitrodiphenyls (HINKEL and HEY), 2790.

$C_{12}H_7O_3NBr_2$ 4:5-Dibromo-3-nitrodiphenyl (HINKEL and HEY), 1839.

$C_{12}H_7O_2N_2Cl_3$ Trichlorodihydroxyazobenzenes (HUNTER and BARNES), 2053.

$C_{12}H_7O_3NCl_4$ 6-Acetylamino-2:4-bisdichloromethylene-1:3-benzdioxin (CHATTAWAY and CALVET), 1091.

$C_{12}H_8ON_2Cl_2$ 4:4′-Dichloroazoxybenzene (BURNS, MCCOMBIE, and SCARBOROUGH), 2933.

3:5-Dichloro-4-hydroxyazobenzene (BURNS, MCCOMBIE, and SCARBOROUGH), 2934.

$C_{12}H_8ON_2I_2$ 3:5-Di-iodo-4-hydroxyazobenzene (HUNTER and BARNES), 2067.

$C_{12}H_8O_2N_2Cl_2$ Dichlorodihydroxyazobenzenes (HUNTER and BARNES), 2053.

$C_{12}H_8O_2N_2Br_2$ Dibromodihydroxyazobenzenes (HUNTER and BARNES), 2052.

$C_{12}H_8O_2N_2I_2$ 5:5′-Di-iodo-2:2′-dihydroxyazobenzene (HUNTER and BARNES), 2057.

$C_{12}H_8O_3N_3Cl$ Chloronitroazobenzenes (BURNS, MCCOMBIE, and SCARBOROUGH), 2933.

$C_{12}H_8O_7N_2S$ Nitrophenyl *p*-nitrobenzenesulphonates (BELL), 2777.

$C_{12}H_9ON_2Br$ 3-Bromo-4-hydroxyazobenzene, and its hydrochloride (HUNTER and BARNES), 2064.

$C_{12}H_9ON_2I$ 3-Iodo-4-hydroxyazobenzene, and its hydrochloride (HUNTER and BARNES), 2064.

$C_{12}H_9O_2N_2Cl$ Chlorodihydroxyazobenzenes (HUNTER and BARNES), 2053.

$C_{12}H_9O_2N_2Br$ Bromodihydroxyazobenzenes (HUNTER and BARNES), 2054.

4′-Bromo-2-nitrodiphenylamine (MCCOMBIE, SCARBOROUGH, and WATERS), 356.

$C_{12}H_9O_2N_2I$ 5-Iodo-2:2′-dihydroxyazobenzene (HUNTER and BARNES), 2057.

$C_{12}H_9O_5NS$ Phenyl *p*-nitrobenzenesulphonate (BELL), 2777.

$C_{12}H_{11}ONSe$ 4-Aminodiphenyl selenoxide (GAYTHWAITE, KENYON, and PHILLIPS), 2291.

$C_{12}H_{11}OClBr_2$ 5-Chloro-4:5-dibromo-1-phenyl*cyclo*hexan-3-one (HINKEL and HEY), 1204.

$C_{12}H_{11}O_2N_2Cl$ 6-Chloronitrotetrahydrocarbazoles (PLANT and ROSSER), 2462.

$C_{12}H_{11}O_3NCl_4$ 6-Acetamido-2:4-bisdichloromethyl-1:3-benzdioxin (CHATTAWAY and MORRIS), 3244.

$C_{12}H_{11}O_3N_2Cl_3$ Ethyl glyoxylate *α*-acetyl-2:4:6-trichlorophenylhydrazone (CHATTAWAY and DALDY), 2760.

Ethyl 2:4:6-trichlorobenzeneazoacetoacetate (CHATTAWAY and DALDY), 2761.

$C_{12}H_{11}O_3N_2Br_3$ Ethyl glyoxylate *α*-acetyl-2:4:6-tribromophenylhydrazone (CHATTAWAY and DALDY), 2762.

Ethyl 2:4:6-tribromobenzeneazoacetoacetate (CHATTAWAY and DALDY), 2762.

$C_{12}H_{12}O_2N_2As_2$ 3:4′-Diamino-4:3′-dihydroxyarsenobenzene (BALABAN), 811.

$C_{12}H_{12}O_3NAs$ Diphenylamine-*p*-arsinic acid, and its hydrochloride (GIBSON and JOHNSON), 1286.

$C_{12}H_{12}O_3N_2S$ Ethyl 4-keto-3:4-dihydroquinazoline-2-thioglycollate (STEPHEN and WILSON), 1421.

$C_{12}H_{12}O_4NBr$ 4-Bromo-2-*iso*nitroso-6:7-dimethoxy-3-methyl-1-hydrindone (KOEPFLI and PERKIN), 2997.

$C_{12}H_{12}O_5Cl_4S$ Ethyl 2:4-bisdichloromethyl-1:3-benzdioxin-6-sulphonate (CHATTAWAY and MORRIS), 3246.

$C_{12}H_{14}O_2N_2S$ Ethyl benziminazolyl-2-*α*-thiolpropionate (STEPHEN and WILSON), 1419.

$C_{12}H_{14}O_2N_2Cl$ *cyclo*Hexanone chloronitrophenylhydrazones (PLANT and ROSSER), 2461.

$C_{12}H_{14}O_3NBr$ 4-Bromo-6:7-dimethoxy-3-methyl-1-hydrindone oxime (KOEPFLI and PERKIN), 2997.

$C_{12}H_{15}O_6N_2As$ 8-Acetamido-3-hydroxy-2-ethyl-1:4-benz*iso*oxazine-6-arsinic acid (NEWBERY, PHILLIPS, and STICKINGS), 3063.

$C_{12}H_{17}O_4NS$ γ-Imino-γ-ethoxypropyl toluene-*p*-sulphonate, hydrochloride of (CLEMO and WATSON), 727.

$C_{13}H_{22}O_5NAs$ γ-Carbethoxy-*n*-hexylaminopropylarsinic acid (GOUGH and KING), 2443.

12 V

$C_{12}H_6O_2N_2Cl_2Br_2$ Dichlorodibromodihydroxyazobenzenes (HUNTER and BARNES), 2060.

$C_{12}H_6O_2N_2Cl_2I_2$ Dichlorodi-iododihydroxybenzenes (HUNTER and BARNES), 2061.

$C_{12}H_6O_2N_2Br_2I_2$ Dibromodi-iododihydroxybenzenes (HUNTER and BARNES), 2062.

$C_{12}H_8ON_2ClBr$ 3-Chloro-5-bromo-4-hydroxyazobenzene (HUNTER and BARNES), 2064.

$C_{12}H_8ON_2ClI$ 3-Chloro-5-iodo-4-hydroxyazobenzene (HUNTER and BARNES), 2065.
$C_{12}H_8ON_2BrI$ 3-Bromo-5-iodo-4-hydroxyazobenzene (HUNTER and BARNES), 2066.
$C_{13}H_8O_3NCl_6Br$ 7-Bromo-6-acetylamino-2:4-bistrichloromethyl-1:3-benzdioxin (CHATTAWAY and CALVET), 1091.

C_{13} Group.

$C_{13}H_{10}N_2$ 1-Methylphenazine, and its chloroplatinate (MCCOMBIE, SCARBOROUGH, and WATERS), 356.
$C_{13}H_{11}O$ Phenyl benzyl ether, rearrangement of (SHORT), 528.
$C_{13}H_{12}O_3$ Methyl 8-methoxy-1-naphthoate (BRETSCHER, RULE, and SPENCE), 1500.
$C_{13}H_{12}Se$ Phenyl *p*-tolyl selenide (GAYTHWAITE, KENYON, and PHILLIPS), 2283.
$C_{13}H_{13}N$ Benzylaniline, nitration of (REILLY, MOORE, and DRUMM), 563.
$C_{13}H_{14}O_3$ Ethyl 1-ketohydrindene-3-acetate (JACKSON and KENNER), 578.
Ethyl 2-methyl-1-hydrindone-2-carboxylate (TITLEY), 2577.
$C_{13}H_{14}O_5$ 3:3′-Dimethoxydiphenylglutaric anhydride (JACKSON and KENNER), 1661.
$C_{13}H_{14}O_6$ 2:4-Diacetylgallacetophenone 3-methyl ether (PERKIN and STOREY), 242.
$C_{13}H_{14}N_2$ 2-Amino-2′-methyldiphenylamine, and its tin salt (MCCOMBIE, SCARBOROUGH, and WATERS), 355.
Propane-$\alpha\gamma$-dipyridine, salts of (GOUGH and KING), 2447.
$C_{13}H_{15}N$ 3-Methyltetrahydrocarbazole (PLANT and ROSSER), 2457.
2:3:4:5-Tetrahydroheptindole, and its picrate (PERKIN and PLANT), 2586.
$C_{13}H_{16}O_2$ 2-Hydroxystyryl *tert.*-butyl ketone (MCGOOKIN and SINCLAIR), 1176.
$C_{13}H_{16}O_3$ Hydroxymethoxystyryl propyl ketones (MCGOOKIN and SINCLAIR), 1174.
$C_{13}H_{16}O_4$ 2-Hydroxystyryl *iso*butenyl ketone (MCGOOKIN and SINCLAIR), 1176.
$C_{13}H_{16}O_6$ 3:3′-Dimethoxydiphenylglutaric acid (JACKSON and KENNER), 1661.
Ethyl syringoylacetate (BRADLEY and ROBINSON), 1554.
$C_{13}H_{17}N$ Hexahydroheptindole, and its salts (PERKIN and PLANT), 2586.
3-Methylhexahydrocarbazoles (PLANT and ROSSER), 2460.
$C_{13}H_{20}O$ Substance, from piperitone and ethyl acetoacetate (JUPP, KON, and LOCKTON), 1644.
$C_{13}H_{20}O_4$ *trans*-Decahydro-β-naphthylmalonic acid (VOGEL), 2027.
$C_{13}H_{22}O$ Luparone (CHAPMAN), 1303.
$C_{13}H_{22}O_4$ Methyl β-*cyclo*hexylglutarate (SIRCAR), 56.
$C_{13}H_{22}N_2$ Base, and its salts, from lupanine methiodide and caustic potash (CLEMO and LEITCH), 1818.
$C_{13}H_{24}O_4$ Methyl hydrogen decane-1:10-dicarboxylate (BHATTACHARYA, SALETORE, and SIMONSEN), 2679.

13 III

$C_{13}H_4O_{10}N_4$ 2:4:5:7-Tetranitroxanthrone (LE FÈVRE), 3251.
$C_{13}H_5O_7N_3$ 2:4:7-Trinitrofluorenone (BELL), 1990.
$C_{13}H_6O_3S$ Thioxanthone dioxide 1:4-quinone (PRICE and SMILES), 3158.
$C_{13}H_8OS_2$ Diphenylene 2:2′-dithiolcarbonate (BARBER and SMILES), 1146.
$C_{13}H_8O_4S$ 2-Hydroxythioxanthone dioxide (PRICE and SMILES), 3158.
$C_{13}H_8O_5S$ Dihydroxythioxanthone dioxides (PRICE and SMILES), 3158.
$C_{13}H_9O_2N$ Carbazole-1-carboxylic acid (BRISCOE and PLANT), 1990.
$C_{13}H_9O_8N_3$ 1-Benzoyloxy-1:2:3-benztriazole (BRADY and REYNOLDS), 197.
$C_{13}H_9NS$ 1-Phenylbenzthiazole, salts of (CLARK), 2316.

$C_{13}H_9N_2Br_3$ Substance, from 2-methylazobenzene and bromine (BURNS, McCOMBIE, and SCARBOROUGH), 2932.

$C_{13}H_{10}ON_2$ 2-Methoxyphenazine, and its chloroplatinate (McCOMBIE, SCARBOROUGH, and WATERS), 358.

$C_{13}H_{10}O_2N_2$ Benzylidene-*m*-nitroaniline, hydrochloride of (FLÜRSCHEIM and HOLMES), 2241.

$C_{13}H_{10}O_2Se$ 4-Carboxydiphenyl selenide (GAYTHWAITE, KENYON, and PHILLIPS),

$C_{13}H_{10}O_3S$ 2-Carboxy-4′-hydroxydiphenyl sulphide (PRICE and SMILES), 2862.

$C_{13}H_{10}O_3Se$ 4-Carboxydiphenyl selenoxide, and its salts (GAYTHWAITE, KENYON, and PHILLIPS), 2284.

$C_{13}H_{10}O_4N_4$ Dinitromethylazobenzenes (BURNS, McCOMBIE, and SCARBOROUGH), 2932.

$C_{13}H_{10}O_4S$ 2-Carboxy-2′:4′-dihydroxydiphenyl sulphide (PRICE and SMILES), 2862.

$C_{13}H_{10}O_5N_4$ 3:4′-Dinitro-4-methoxyazobenzene (BURNS, McCOMBIE, and SCARBOROUGH), 2935.

$C_{13}H_{10}O_5S$ 2:4-Dihydroxy-2′-carboxydiphenyl sulphoxide (PRICE and SMILES), 3157.

$C_{13}H_{10}O_6S$ 2:5-Dihydroxydiphenylsulphone-2′-carboxylic acid (PRICE and SMILES), 3156.

$C_{13}H_{11}O_3N_3$ Nitromethylazobenzenes (BURNS, McCOMBIE, and SCARBOROUGH),

$C_{13}H_{11}O_4N$ 7-Methyl-3:4-dihydrocoumarin-4-cyanoacetic acid (SESHADRI), 170.

$C_{13}H_{11}NS$ Thiobenzanilide, thermal decomposition of (CHAPMAN), 1894.

$C_{13}H_{11}N_2Br$ Bromomethylazobenzenes (BURNS, McCOMBIE, and SCARBOROUGH), 2931.

$C_{13}H_{12}OSe$ Phenyl *p*-tolyl selenoxide (GAYTHWAITE, KENYON, and PHILLIPS), 2284.

$C_{13}H_{12}O_2N_2$ 2-Aminodiphenylamine-2′-carboxylic acid, and its hydrochloride (McCOMBIE, SCARBOROUGH, and WATERS), 358.

2-Nitro-2′-methyldiphenylamine (McCOMBIE, SCARBOROUGH, and WATERS), 355.

$C_{13}H_{12}O_2S$ Phenylbenzylsulphone, parachor for (FREIMAN and SUGDEN), 268.

$C_{13}H_{12}O_3N_2$ 7-Methyl-3:4-dihydrocoumarin-4-cyanoacetamide (SESHADRI), 170.

2-Nitromethoxydiphenylamines (McCOMBIE, SCARBOROUGH, and WATERS), 357.

$C_{13}H_{12}SeBr_2$ Phenyl *p*-tolyl selenide dibromide (GAYTHWAITE, KENYON, and PHILLIPS), 2283.

$C_{13}H_{12}SnCl_2$ Phenylbenzylstannic chloride (KIPPING), 2368.

$C_{13}H_{13}O_2N$ Acetyl-2-methoxy-3-naphthylamine (CLEMO and SPENCE), 2818.

$C_{13}H_{13}O_2I$ 2-Phenyl-6-methyl-4-pyrone methiodide (GIBSON and SIMONSEN), 2310.

$C_{13}H_{18}O_3N_2$ Methyl 1-ketohydrindene-3-acetate semicarbazone (JACKSON and KENNER), 578.

$C_{13}H_{12}O_4N$ *iso*Nitroso-derivative of ethyl 1-ketohydrindene-3-acetate (JACKSON and KENNER), 578.

$C_{13}H_{14}ON_2$ 2-Aminomethoxydiphenylamines (McCOMBIE, SCARBOROUGH, and WATERS), 357.

$C_{13}H_{14}O_2N_2$ Nitro-3-methyltetrahydrocarbazoles (PLANT and ROSSER), 2457.

$C_{13}H_{14}O_3N_2$ 1-Acetyl-2-pyrrolidone-5-carboxyanilide (GRAY), 1266.

$C_{13}H_{14}NBr$ 7-Bromo-2:3:4:5-tetrahydroheptindole (PERKIN and PLANT), 2587.

$C_{13}H_{15}ON$ 8-Acetyltetrahydropentindole (PLANT and RIPPON), 1911.

Hexahydroacridone (PERKIN and PLANT), 2590.

$C_{13}H_{15}O_2N_3$ *aa'*-Dicyano-*a*-methyl*cyclo*pentane-1:1-diacet-*N*-methyl-*ω*-imide (BARDHAN), 2596.

1-*p*-Nitroanilino-1-cyano*cyclo*hexane (BETTS and PLANT), 2074.

$C_{13}H_{15}O_4Cl$ Ethyl phenylchloromalonate (FLÜRSCHEIM and HOLMES), 1613.

$C_{13}H_{16}ON_2$ Hexahydroacridoneoxime (PERKIN and PLANT), 2590.

$C_{13}H_{16}O_4N_2$ 1-*p*-Nitroanilino*cyclo*hexane-1-carboxylic acid (BETTS and PLANT), 2074.

$C_{13}H_{17}O_3N_3$ 1-*p*-Nitroanilino*cyclo*hexane-1-carboxyamide (BETTS and PLANT), 2074.

$C_{13}H_{17}O_6N$ Diethyl hydrogen 3-amino-1-methyl*dicyclo*pentane-2:4:5-tricarboxylate (GOSS and INGOLD), 1277.

$C_{13}H_{18}O_2N_2$ 1-*p*-Aminoanilino*cyclo*hexane-1-carboxylic acid (BETTS and PLANT), 2074.

αγ-Diacetylamino-*δ*-phenylpropane (JACKSON and KENNER), 1659.

$C_{13}H_{19}O_2N$ Ethyl *a*-ethyl-Δ^1-*cyclo*hexenylcyanoacetate (MCRAE and MANSKE), 486.

$C_{13}H_{20}O_4N_4$ 3:3'-Dimethoxydiphenylglutaric dihydrazide (JACKSON and KENNER), 1661.

$C_{13}H_{20}O_5N_2$ Dimethyl *γ*-xylonolactone phenylhydrazide (HAWORTH and PORTER), 617.

2-Methylglucosephenylhydrazone (HICKINBOTTOM), 3146.

$C_{13}H_{21}O_4N$ Ethyl *a*-cyano-*a*-*iso*propylglutarate (HARIHARAN, MENON, and SIMONSEN), 434.

$C_{13}H_{22}O_5N_4$ Di(ethyl acetoacetate)carbohydrazone (MUNRO and WILSON), 1260.

$C_{13}H_{25}OBr$ Methyl 11-bromodecoate (BHATTACHARYA, SALETORE, and SIMONSEN), 2680.

$C_{13}H_{26}ON_4$ Dipinacolincarbohydrazone (MUNRO and WILSON), 1259.

13 IV

$C_{13}H_4O_6N_2Br_2$ 2:7-Dibromo-4:6-dinitroxanthone (LE FÈVRE), 3251.

$C_{13}H_7O_5ClS$ Chloro-1:4-dihydroxythioxanthone dioxide (PRICE and SMILES), 3158.

$C_{13}H_8O_4NF$ Fluoronitrophenyl benzoates (HODGSON and NIXON), 1880.

$C_{13}H_8O_7N_5Cl$ Chlorodinitrohydroxybenzaldehyde *p*-nitrophenylhydrazones (HODGSON and JENKINSON), 2274.

$C_{13}H_8O_7N_5Br$ Bromodinitrohydroxybenzaldehyde *p*-nitrophenylhydrazones (HODGSON and JENKINSON), 2277.

$C_{13}H_8O_7N_5I$ Iododinitrohydroxybenzaldehyde *p*-nitrophenylhydrazones (HODGSON and JENKINSON), 2279.

$C_{13}H_9ON_2Br_3$ 3:4':5'-Tribromo-4-methoxyazobenzene (BURNS, MCCOMBIE, and SCARBOROUGH), 2934.

$C_{13}H_9OClTe$ Chloromethylphenoxtellurine, and its salts (DREW), 510.

$C_{13}H_9O_3N_2Br$ Dibromonitrohydroxybenzaldehyde phenylhydrazones (HODGSON and JENKINSON), 2278.

$C_{13}H_9O_3N_2Br_2$ Dibromohydroxybenzaldehyde *p*-nitrophenylhydrazones (HODGSON and JENKINSON), 2275.

$C_{13}H_9O_5N_4Cl$ Chlorodinitrohydroxybenzaldehyde phenylhydrazones (HODGSON and JENKINSON), 2274.

Chloronitrohydroxybenzaldehyde *p*-nitrophenylhydrazones (HODGSON and JENKINSON), 2273.

$C_{13}H_9O_5N_4Br$ Bromodinitrohydroxybenzaldehyde phenylhydrazones (HODGSON and JENKINSON), 2277.

Bromonitrohydroxybenzaldehyde *p*-nitrophenylhydrazones (HODGSON and JENKINSON), 2277.

$C_{13}H_9O_5N_4I$ Iododinitrohydroxybenzaldehyde phenylhydrazones (HODGSON and JENKINSON), 2279.

Iodonitrohydroxybenzaldehyde *p*-nitrophenylhydrazones (HODGSON and JENKINSON), 2279.

$C_{13}H_9O_6ClS$ Chloro-2:5-dihydroxydiphenylsulphone-2′-carboxylic acid (PRICE and SMILES), 3157.

$C_{13}H_{10}ON_2Cl_2$ 3:5-Dichloro-4-methoxyazobenzene (BURNS, MCCOMBIE, and SCARBOROUGH), 2934.

$C_{13}H_{10}ON_2Br_2$ 3:4′-Dibromo-4-methoxyazobenzene (BURNS, MCCOMBIE, and SCARBOROUGH), 2934.

$C_{13}H_{10}O_2N_2Br$ *m*-Nitrobenzylidene-*p*-bromoaniline (NISBET), 3123.

$C_{13}H_{10}O_2N_3Cl$ Chlorobenzaldehyde nitrophenylhydrazones (HODGSON and HANDLEY), 1885.

$C_{13}H_{10}O_3N_3Cl$ Chloronitrohydroxybenzaldehyde phenylhydrazones (HODGSON and JENKINSON), 2273.

$C_{13}H_{10}O_3N_3Br$ Bromonitrohydroxybenzaldehyde phenylhydrazones (HODGSON and JENKINSON), 2277.

$C_{13}H_{10}O_3N_3I$ Iodonitrohydroxybenzaldehyde phenylhydrazones (HODGSON and JENKINSON), 2279.

$C_{13}H_{10}O_7N_2S$ Nitro-*p*-tolyl *p*-nitrobenzesulphonates (BELL), 2777.

$C_{13}H_{10}O_8N_4S$ *p*-Nitrobenzenesulphon-3:5-dinitro-*p*-tolylamide (BELL), 2777.

$C_{13}H_{11}ON_2Br$ 3-Bromo-4-methoxyazobenzene (BURNS, MCCOMBIE, and SCARBOROUGH), 2934.

$C_{13}H_{11}O_5NS$ *p*-Tolyl *p*-nitrobenzenesulphonate (BELL), 2777.

$C_{13}H_{12}O_4N_2S$ *p*-Nitrobenzenesulphon-*p*-tolylamide (BELL), 2777.

$C_{13}H_{14}ONP$ Phenylmethylphosphinanilide (GIBSON and JOHNSON), 96.

$C_{13}H_{14}O_2N_3Br$ α-Bromo-αα′-dicyano-α′-methyl*cyclo*pentane-1:1-diacetmethylimide (BARDHAN), 2599.

$C_{13}H_{16}ON_2S$ Acetyl derivative of 1-*n*-propylamino-3-methylbenzthiazole (HUNTER and STYLES), 3026.

$C_{13}H_{16}O_2N_2S$ Ethyl benziminazolyl-2-α-thiol-*n*-butyrate (STEPHEN and WILSON), 1419.

$C_{13}H_{12}O_6N_2As$ *m*-Nitrobenzopropylamidopropylarsinic acid (GOUGH and KING), 2442.

13 V

$C_{13}H_{14}O_5N_2SAs_2$ 3:3′-Diamino-4:4′-dihydroxyarsenobenzene-*NN′*-dimethylenesulphurous acid, and its sodium salt (NEWBERY and PHILLIPS), 125.

C_{14} Group.

$C_{14}H_{10}O$ 1-Phenanthrol (SHOESMITH and GUTHRIE), 2333.

$C_{14}H_{10}O_5$ *O*-Benzoylphloroglucinaldehyde, preparation and constitution of (ROBERTSON, ROBINSON, and STRUTHERS), 1455.

$C_{14}H_{12}O_2$ Benzoin, resolution of (HOPPER and WILSON), 2483.

$C_{14}H_{12}N_2$ 3-*o*-Aminophenylindole, and its salts (KERMACK and SLATER), 40.

$C_{14}H_{12}Cl_2$ 5:5′-Dichloro-3:3′-ditolyl (MCALISTER and KENNER), 1915.

$C_{14}H_{14}O$ Dibenzyl ether as a cryoscopic solvent (BENNETT and WILLIS), 2305.

Phenylbenzylcarbinol, resolution of, and its salts (GERRARD and KENYON), 2564.

$C_{14}H_{14}S_2$ 3:3′-Dimethylthioldiphenyl (BARBER and SMILES), 1147.

s-Diphenylthiolethane (BELL and BENNETT), 3190.

$C_{14}H_{16}O_2$ 4-Acetonyl-2:3-dimethyl-1:4-benzopyran (HILL), 257.

$C_{14}H_{16}O_3$ Ethyl 1-keto-2-methyl-1:2:3:4-tetrahydronaphthalene-2-carboxylate (TITLEY), 2577.

$C_{14}H_{16}O_4$ Ethyl *p*-carboxycinnamate (TITLEY), 2581.
$C_{14}H_{18}O_4$ Ethyl *β-o*-carboxyphenylpropionate (TITLEY), 2576.
Ethyl *m*-phenylenediacetates (TITLEY), 2579.
Ethyl *β*-veratrylcrotonate (KOEPFLI and PERKIN), 2995.
$C_{14}H_{18}O_5$ Methyl *β-p*-methoxyphenylglutarate (JACKSON and KENNER), 1660.
$C_{14}H_{18}O_7$ Methyl 5-methylethyl*dicyclo*pentan-3-one-1:2:4-tricarboxylate (Goss and INGOLD), 1273.
$C_{14}H_{19}N$ Octahydroheptaquinoline (PERKIN and PLANT), 2588.
$C_{14}H_{22}O$ Aromadendrone (BRIGGS and SHORT), 2528.
$C_{14}H_{22}O_2$ 5-Acetyl-1-methyl-3:4-dipropenyl*cyclo*pentan-1-ol (EVANS and FARMER), 1647.
$C_{14}H_{22}O_8$ Ethyl ethanetetracarboxylate, sodium salt, action of dibromotetracarboxylic esters on (LENNON and PERKIN), 1513.
$C_{14}H_{22}O_9$ 3:4:6-Triacetyl *β*-ethylglucoside (HICKINBOTTOM), 3145.
$C_{14}H_{24}O_4$ Diethyl *α*-methyl*cyclo*pentane-1:1-diacetate (BARDHAN), 2599.

14 III

$C_{14}H_7ClBr_2$ 1-Chloro-9:10-dibromoanthracene (COOK), 2808.
$C_{14}H_8O_4Cl_2$ 5:5′-Dichlorodiphenyl-3:3′-dicarboxylic acid, and its salts (MCALISTER and KENNER), 1916.
$C_{14}H_8O_6N_2$ Dinitrobenzils (CHATTAWAY and COULSON), 1086.
$C_{14}H_8O_9N_4$ 3:3′:4′:5-Tetranitro-4-methylbenzophenone (BLAKEY and SCARBOROUGH), 2494.
$C_{14}H_9O_2N_3$ Nitro-3-phenylphthalazones (ROWE and LEVIN), 2553; (ROWE, HIMMAT, and LEVIN), 2561.
$C_{14}H_9O_4N$ Nitrobenzils (CHATTAWAY and COULSON), 1084.
$C_{14}H_9O_4N_3$ 1:4-Diketo-3-(3′-nitrophenyl)-tetrahydrophthalazine (ROWE, HIMMAT, and LEVIN), 2563.
1:4-Diketo-3-(4′-nitrophenyl)tetrahydrophthalazine (ROWE and LEVIN), 2554.
$C_{14}H_9O_7N_3$ 3:4′:5-Trinitro-4-methylbenzophenone (BLAKEY and SCARBOROUGH), 2493.
$C_{14}H_{10}O_2N_2$ 3-*o*-Nitrophenylindole (KERMACK and SLATER), 39.
$C_{14}H_{10}O_4S$ 2-Methoxythioxanthone dioxide (PRICE and SMILES), 3159.
$C_{14}H_{10}O_4Se_2$ 4:4′-Dicarboxydiphenyl diselenide (GAYTHWAITE, KENYON, and PHILLIPS), 2286.
$C_{14}H_{10}O_5N_2$ Dinitro-4-methylbenzophenones (BLAKEY and SCARBOROUGH), 2493.
$C_{14}H_{10}O_5S$ Methyl-1:4-dihydroxythioxanthone dioxide (PRICE and SMILES), 3158.
$C_{14}H_{10}O_6Se$ Disalicylyl selenide (MORGAN and BURSTALL), 3270.
$C_{14}H_{10}N_4As_2$ Arsenobenziminazoles (PHILLIPS), 3137.
$C_{14}H_{11}ON_3$ Amino-3-phenylphthalazones (ROWE and LEVIN), 2553; (ROWE, HIMMAT, and LEVIN), 2560.
$C_{14}H_{11}OBr$ 3-Bromo-4-methylbenzophenone (BLAKEY and SCARBOROUGH), 2492.
$C_{14}H_{11}O_2N$ 3′-Hydroxy-*N*-phenylphthalimidine (ROWE, HIMMAT, and LEVIN), 2561.
$C_{14}H_{11}O_2N_3$ 1-Benzoyloxy-6-methyl-1:2:3-benztriazole (BRADY and REYNOLDS), 200.
$C_{14}H_{11}O_2Cl$ 4-Chlorodiphenylmethane-2′-carboxylic acid (BARNETT and WILTSHIRE), 1823.
$C_{14}H_{11}O_3N$ 3-Nitro-4-methylbenzophenone (BLAKEY and SCARBOROUGH), 2492.
$C_{14}H_{11}O_4N_3$ *o*-Carboxybenzaldehyde-*p*-nitrophenylhydrazone (ROWE and LEVIN), 2555.
$C_{14}H_{11}O_5N_3$ 3:5-Dinitro-4-acetamidodiphenyl (BELL), 2776.

$C_{14}H_{12}ON_2$ 3′-Amino-*N*-phenylphthalimidine (ROWE, HIMMAT, and LEVIN), 2560.

$C_{14}H_{12}O_3N_2$ 5-Nitro-2-acetamidodiphenyl (BELL), 2774.

Nitroamino-4-methylbenzophenones (BLAKEY and SCARBOROUGH), 2493.

$C_{14}H_{12}O_6S$ Methyl 2:5-dihydroxydiphenylsulphone-2′-carboxylate (PRICE and SMILES), 3157.

$C_{14}H_{12}Cl_2S_2$ 4:4′-Dichloro-3:3′-dimethylthioldiphenyl (BARBER and SMILES), 1147.

$C_{14}H_{12}I_2S_2$ Di-4-iodo-*m*-tolyl disulphide (BARBER and SMILES), 1144.

$C_{14}H_{13}ON$ 3-Amino-4-methylbenzophenone, and its hydrobromide (BLAKEY and SCARBOROUGH), 2492.

Desylamines, hydrochlorides of (MCKENZIE and WALKER), 650.

$C_{14}H_{13}OCl$ 5-Chloro-3-ethoxydiphenyl (HINKEL and HEY), 1204.

$C_{14}H_{13}OBr$ 5-Bromo-3-ethoxydiphenyl (HINKEL and HEY), 1203.

$C_{14}H_{13}O_2Cl$ 5-Chloro-4:4′-dihydroxy-3:3′-ditolyl (MORGAN and BURSTALL), 3268.

$C_{14}H_{13}O_3N_3$ Methoxybenzaldehydenitrophenylhydrazones (HODGSON and HANDLEY), 1885.

3-Nitro-4′:5-diamino-4-methylbenzophenone (BLAKEY and SCARBOROUGH), 2494.

$C_{14}H_{13}O_6Al$ Aluminosalicylic acid, and its salts (BURROWS and WARK), 225.

$C_{14}H_{14}ON_2$ *N*-Acetyl-*p*-aminodiphenylamine (GIBSON and JOHNSON), 1286.

$C_{14}H_{14}O_2S_2$ Diphenylthiolethane disulphoxides (BELL and BENNETT), 3190.

$C_{14}H_{14}O_2Se$ Dihydroxydimethyldiphenyl selenides (MORGAN and BURSTALL), 3267.

$C_{14}H_{14}O_3N_2$ Ethyl 2-methylquinoxaline-3-pyruvate (BENNETT and WILLIS), 1973.

$C_{14}H_{14}O_4N_2$ Dinitrotolidines, isomerism of (LE FÈVRE and TURNER), 963.

$C_{14}H_{14}N_2S$ Benzaldehyde-*p*-methylthiolphenylhydrazone (HODGSON and HANDLEY), 1886.

$C_{14}H_{14}ClSb$ Di-*p*-tolylchlorostibine (GODDARD and YARSLEY), 720.

$C_{14}H_{14}Cl_2Si$ Dibenzylsilicon dichloride, action of sodium on (STEELE and KIPPING), 1431.

$C_{14}H_{14}Cl_2Sb$ Di-*p*-tolylstibine trichloride (GODDARD and YARSLEY), 721.

$C_{14}H_{14}BrSb$ Di-*p*-tolylbromostibine (GODDARD and YARSLEY), 721.

$C_{14}H_{14}ISb$ Di-*p*-tolyliodostibine (GODDARD and YARSLEY), 721.

$C_{14}H_{15}ON$ Ketohexahydroheptaquinoline (PERKIN and PLANT), 2583.

$C_{14}H_{15}O_2N$ *cyclo*Pentane-1-acetic-1-carboxylic acid (BARDHAN), 2600.

$C_{14}H_{15}O_2Sb$ Di-*p*-tolylstibinic acid (GODDARD and YARSLEY), 721.

$C_{14}H_{15}O_7N$ Ethyl phenylcyanomalonate (FLÜRSCHEIM and HOLMES), 2236.

$C_{14}H_{16}O_3N_2$ Nitromethyl-ψ-indoxyl*spirocyclo*hexanes (BETTS and PLANT), 2072.

$C_{14}H_{16}O_6S$ 2-Phenyl-6-methyl-4-pyrone methylmethosulphate (GIBSON and SIMONSEN), 2310.

$C_{14}H_{17}ON$ Acetylhexahydroquinidenes (PERKIN and PLANT), 644.

Methyl-ψ-indoxyl*spirocyclo*hexanes (BETTS and PLANT), 2072.

$C_{14}H_{17}O_3N$ 1-Carboxy*cyclo*pentane-1-acetanilic acid (VOGEL), 2022.

*cyclo*Pentane-1-acetic-1-carboxylic anilic acid (BARDHAN), 2600.

$C_{14}H_{17}O_3N_3$ Ethyl 1-ketohydrindene-3-acetate semicarbazone (JACKSON and KENNER), 578.

$C_{14}H_{19}ON$ αβ-Dimethylpentenoic-*p*-toluidides (ABBOTT, KON, and SATCHELL), 2519.

$C_{14}H_{19}O_2N$ 1-Anilino-4-methyl*cyclo*hexane-1-carboxylic acid (BETTS and PLANT), 2073.

1-Toluidino*cyclo*hexane-1-carboxylic acids (BETTS and PLANT), 2071.

$C_{14}H_{19}O_2Tl$ Thallium diethyl benzoylacetone (MENZIES, SIDGWICK, CUTCLIFFE, and FOX), 1290.

$C_{14}H_{19}O_4N_3$ *aaβ*-Trimethyl-lævulic acid *p*-nitrophenylhydrazone (BARDHAN), 2616.

$C_{14}H_{22}O_5N_2$ 2:3:4-Trimethyl-lyxonic acid phenylhydrazide (HIRST and SMITH), 3153.

Trimethyl-γ-xylonolactone phenylhydrazide (HAWORTH and PORTER), 617.

$C_{14}H_{22}O_6Mo$ Molybdyl bisdipropionylmethane (MORGAN and CASTELL), 3254.

Molybdyl bis-3-ethylacetylacetone (MORGAN and CASTELL), 3255.

$C_{14}H_{22}ON$ Aromadendrone oxime (BRIGGS and SHORT), 2528.

$C_{14}H_{22}ON_2$ Δ^1-Pulegenylacetone semicarbazone (JUPP, KON, and LOCKTON), 1643.

$C_{14}H_{23}O_4Br$ Ethyl *α*-bromo-*α'*-methyl*cyclo*pentane-1:1-diacetate (BARDHAN), 2589.

$C_{14}H_{24}O_6N_6$ Di(ethyl acetoacetate) dicarbohydrazone (MUNRO and WILSON), 1260.

$C_{14}H_{28}O_2N_6$ Dipinacolinhydrazidicarbohydrazone (MUNRO and WILSON), 1259.

14 IV

$C_{14}H_8ONCl$ 2'-Cyanodiphenyl-2-carboxylyl chloride (BELL), 3248.

$C_{14}H_8O_7N_3Cl$ 4'-Chloro-3:3':5-trinitro-4-methylbenzophenone (BLAKEY and SCARBOROUGH), 2495.

$C_{14}H_9O_5NS$ 3-Keto-2-*p*-nitrophenyl-2:3-dihydrothionaphthen 1:1-dioxide (PRICE and SMILES), 2862.

$C_{14}H_9O_5N_2Cl$ Chlorodinitro-4-methylbenzophenones (BLAKEY and SCARBOROUGH), 2495.

$C_{14}H_9O_5N_2Br$ 3-Bromo-3':5'-dinitro-4-methylbenzophenone (BLAKEY and SCARBOROUGH), 2494.

$C_{14}H_{10}OClBr$ 4'-Chloro-3-bromo-4-methylbenzophenone (BLAKEY and SCARBOROUGH), 2495.

$C_{14}H_{10}O_2N_2I_2$ 3:5-Di-iodo-4-acetoxyazobenzene (HUNTER and BARNES), 2067.

$C_{14}H_{10}O_3NCl$ Chloronitro-4-methylbenzophenones (BLAKEY and SCARBOROUGH), 2495.

$C_{14}H_{10}O_3NBr$ Bromonitro-4-methylbenzophenones (BLAKEY and SCARBOROUGH), 2494.

$C_{14}H_{10}O_4N_2Cl_2$ Dichlorodinitro-3:3'-dimethyldiphenyl (LE FÈVRE and TURNER), 968.

$C_{14}H_{10}O_4N_2Br_2$ Dibromodinitro-3:3'-dimethyldiphenyls (LE FÈVRE and TURNER), 967.

$C_{14}H_{11}ONCl$ Dichloroacetamidodiphenyls (HINKEL and HEY), 2790.

$C_{14}H_{11}ONBr_2$ 4:5-Dibromo-3-acetamidodiphenyl (HINKEL and HEY), 1840.

$C_{14}H_{11}O_2N_2Br$ 3-Bromo-4-acetoxyazobenzene (HUNTER and BARNES), 2064.

$C_{14}H_{11}O_2N_2I$ 3-Iodo-4-acetoxyazobenzene (HUNTER and BARNES), 2064.

$C_{14}H_{11}O_3NS$ *m*-Tolyl *p*-nitrothiolbenzoate (BARBER and SMILES), 1147.

$C_{14}H_{11}O_6NS$ *o*-Carboxyphenyl-*p*-nitrobenzylsulphone (PRICE and SMILES), 2861.

p-Nitrobenzyl *o*-carboxybenzenesulphinate (PRICE and SMILES), 2861.

$C_{14}H_{12}ONCl$ 4'-Chloro-3-amino-4-methylbenzophenone (BLAKEY and SCARBOROUGH), 2495.

$C_{14}H_{12}ONBr$ 5-Bromo-3-acetylaminodiphenyl (HINKEL and HEY), 1839.

Bromoamino-4-methylbenzophenones (BLAKEY and SCARBOROUGH), 2494.

$C_{14}H_{12}ON_2Cl$ 3-Chloro-4-acetamidoazobenzene (BURNS, MCCOMBIE, and SCARBOROUGH), 2935.

$C_{14}H_{12}O_2NCl$ Benzoyl derivative of 3-chloro-2-aminoanisole (HODGSON and KERSHAW), 192.

$C_{14}H_{12}O_3N_2Cl$ Nitrobenzaldehyde-3-chloroanisyl-2-hydrazone (HODGSON and KERSHAW), 193.

$C_{14}H_{12}O_4N_2S_4$ 4:4′-Dinitro-5:5′-dimethylthioldiphenyl disulphide (HODGSON and HANDLEY), 163.
$C_{14}H_{12}O_4N_2Se_2$ Di-2-nitro-*p*-tolyl diselenide (CHALLENGER and PETERS), 1369.
$C_{14}H_{12}O_4Cl_2S_2$ 4:4′-Dimethyldiphenyl-2:2′-disulphonyl chloride (BARBER and SMILES), 1147.
$C_{14}H_{12}O_6N_2S$ Dinitro-5:5-dimethoxydiphenyl sulphides (HODGSON and HANDLEY), 626.
$C_{14}H_{12}O_8N_2S$ Dinitro-5:5-dimethoxydiphenylsulphones (HODGSON and HANDLEY), 627.
$C_{14}H_{13}ONSe$ 4-Acetamidodiphenyl selenide (GAYTHWAITE, KENYON, and PHILLIPS), 2290.
$C_{14}H_{13}ON_2Cl$ Benzaldehyde-3-chloroanisyl-2-hydrazone (HODGSON and KERSHAW), 193.
6-Chloro-5-benzeneazo-*o*-4-xylenol (HINKEL, AYLING, and BEVAN), 2532.
$C_{14}H_{13}O_3NS$ 2-Benzenesulphonyldihydro*iso*indole (FENTON and INGOLD), 3295.
$C_{14}H_{13}O_2NSe$ 4-Acetamidodiphenyl selenoxide (GAYTHWAITE, KENYON, and PHILLIPS), 2291.
$C_{14}H_{13}O_2N_3S$ Methylthiobenzaldehydenitrophenylhydrazones (HODGSON and HANDLEY), 1885.
$C_{14}H_{13}O_3N_2Cl$ 6-Chloronitro-9-acetyltetrahydrocarbazole (PLANT and ROSSER), 2462.
$C_{14}H_{12}O_4NCl_4$ 6-Diacetamido-2:4-bisdichloromethyl-1:3-benzdioxin (CHATTAWAY and MORRIS), 3244.
$C_{14}H_{14}ONCl$ 6-Chloro-9-acetyltetrahydrocarbazole (PLANT and ROSSER), 2462.
$C_{14}H_{14}O_3N_2As_2$ 4-Amino-4′-acetamido-3:3′-dihydroxyarsenobenzene (BALABAN), 811.
$C_{14}H_{15}O_3NSe$ 4-Acetamidodiphenyl selenide dihydroxide (GAYTHWAITE, KENYON, and PHILLIPS), 2290.
$C_{14}H_{16}O_2N_2S_2$ Diamino-5:5-dimethoxydiphenyl disulphides (HODGSON and HANDLEY), 627.
$C_{14}H_{16}O_3NCl$ 6-Chloro-10:11-dihydroxy-9-acetylhexahydrocarbazole (PLANT and ROSSER), 2462.
$C_{14}H_{21}O_4N_2As$ γ-4-Benzoylpiperazinopropylarsinic acid (GOUGH and KING), 2445.

14 V

$C_{14}H_{10}O_3N_2ClBr$ 3-Chloro-5-bromo-4-acetoxyazobenzene (HUNTER and BARNES), 2065.
$C_{14}H_{10}O_3N_2ClI$ 3-Chloro-5-iodo-4-acetoxyazobenzene (HUNTER and BARNES), 2065.
$C_{14}H_{10}O_3N_2BrI$ 3-Bromo-5-iodo-4-acetoxyazobenzene (HUNTER and BARNES), 2066.
$C_{14}H_{12}ONClS$ 4-Chloro-2-thiobenzanisidine (HODGSON and HANDLEY), 163.
$C_{14}H_{13}ONCl_2Se$ 4-Acetamidodiphenyl selenide dichloride (GAYTHWAITE, KENYON, and PHILLIPS), 2292.
$C_{14}H_{13}ONBr_2Se$ 4-Acetamidodiphenyl selenide dibromide (GAYTHWAITE, KENYON, and PHILLIPS), 2292.
$C_{14}H_{13}ONI_2Se$ 4-Acetamidodiphenyl selenide di-iodide (GAYTHWAITE, KENYON, and PHILLIPS), 2293.

C_{15} Group.

$C_{15}H_{24}$ Aromadendrene, chemistry of (BRIGGS and SHORT), 2524.
Caryophyllene, reaction for (GIBSON), 750.
$C_{15}H_{26}$ Dihydroaromadendrene (BRIGGS and SHORT), 2527.
$C_{15}H_{30}$ Hexahydrocurcumene (RAO and SIMONSEN), 2504.

15 II

$C_{15}H_{10}O_4$ Purpuroxanthin 1-methyl ester (PERKIN and STOREY), 239.
$C_{15}H_{10}O_5$ Anthrapurpurin methyl ethers (PERKIN and STOREY), 235.
1:4-Diacetylpurpurin 2-methyl ether (PERKIN and STOREY), 238.
Genistein, synthesis of (BAKER and ROBINSON), 3115.
$C_{15}H_{10}O_5$ Irigenol, and its sulphate (BAKER), 1030.
$C_{15}H_{10}N_2$ 5:6-Benz-4-carboline (KERMACK and SLATER), 32.
$C_{15}H_{11}N$ 2:3-Indeno(1:2)-indole (TITLEY), 2576.
$C_{15}H_{11}Cl$ 2-Chloro-9-methylanthracene (BARNETT and WILTSHIRE), 1824.
$C_{15}H_{12}O_4$ ω-Hydroxy-4-benzoyloxyacetophenone (ROBERTSON and ROBINSON), 1465.
α-Naphthylparaconic acid (SHOESMITH and GUTHRIE), 2332.
$C_{15}H_{14}N_2$ 3-*o*-Aminophenyl-1-methylindole, and its salts (KERMACK and SLATER), 44.
$C_{15}H_{14}S_2$ Acetonediphenylene-2:2′-mercaptol (BARBER and SMILES), 1146.
$C_{15}H_{16}N_2$ 1-Cyano*cyclo*hexylphenylacetonitrile (MCRAE and MANSKE), 490.
$C_{15}H_{19}N$ α-Phenyl-β-*n*-hexylacrylonitrile (MCRAE and MANSKE), 490.
$C_{15}H_{20}O_4$ Ethyl γ-*o*-carbethoxyphenyl-*n*-butyrate (TITLEY), 2577.
Ethyl β-phenylglutarate (JACKSON and KENNER), 1658.
$C_{15}H_{20}O_6$ Methyl 3:3′-dimethoxydiphenylglutarate (JACKSON and KENNER), 1661.
$C_{15}H_{20}O_7$ Ethyl 5-methyl*dicyclo*penten-3-ol-1:2:4-tricarboxylate (GOSS and INGOLD), 1272.
$C_{15}H_{24}O$ Luparenol (CHAPMAN), 1304.
$C_{15}H_{24}O_3$ Ngaiol, isomeride of (MCDOWALL), 1331.
$C_{15}H_{24}O_9$ 3:4:6-Triacetyl-2-methyl β-ethylglucoside (HICKINBOTTOM), 3145.
$C_{15}H_{25}Cl$ *l*-α-Curcumene hydrochloride (RAO and SIMONSEN), 2501.
$C_{15}H_{26}O_4$ *l*-Menthyl hydrogen glutarate (RULE, HAY, and PAUL), 1357.
$C_{15}H_{26}N_2$ Deoxylupanine, and its salts (CLEMO and LEITCH), 1818.
$C_{15}H_{28}O_3$ *l*-Menthyl propoxyacetate (RULE, HAY, and PAUL), 1355.
$C_{15}H_{30}O_2$ Substance, from hydrogenation of ngaiol (MCDOWALL), 1327.
$C_{15}H_{32}O$ Substance, from reduction of tetrahydrongaiol (MCDOWALL), 1329.

15 III

$C_{15}H_{10}ON_2$ 3-Keto-3:4-dihydro-5:6-benz-4-carboline (KERMACK and SLATER), 39.
$C_{15}H_{10}O_4N_2$ 3-*o*-Nitrophenylindole-2-carboxylic acid, and its salts (KERMACK and SLATER), 38.
$C_{15}H_{10}N_2Br_2$ 3-Phenyl-2-ω-dibromomethylquinoxaline (BENNETT and WILLIS), 1974.
$C_{15}H_{11}O_2Cl$ Phenyl *p*-chlorobenzyl ketone (BENNETT and WILLIS), 1966.
$C_{15}H_{11}O_4N_3$ 4-Keto-1-methoxy-3-(3′-nitrophenyl)-3:4-dihydrophthalazine (ROWE, HIMMATT, and LEVIN), 2562.
4-Keto-1-methoxy-3-(4′-nitrophenyl)-3:4-dihydrophthalazine (ROWE and LEVIN), 2554.
$C_{15}H_{11}O_5Cl$ Pelargonidin chloride (ROBERTSON, ROBINSON, and SUGIURA), 1534.
$C_{15}H_{11}O_6Cl$ Cyanidin chloride (ROBERTSON and ROBINSON), 1528.
$C_{15}H_{12}O_3N_2$ 3-*o*-Nitrophenyl-1-methylindole (KERMACK and SLATER), 44.
$C_{15}H_{12}O_2Cl_2$ Benzoyldichloro-*o*-4-xylenols (HINKEL, AYLING, and BEVAN), 2537.
$C_{15}H_{12}O_4N_2$ β-Phenylglutardiurethane (JACKSON and KENNER), 1658.
$C_{15}H_{12}O_5S$ Dimethoxythioxanthone dioxides (PRICE and SMILES), 3158.
$C_{15}H_{13}OCl$ *p*-Chlorophenyl β-phenylethyl ketone (BURTON and INGOLD), 920.
Phenyl β-*p*-chlorophenylethyl ketone (BURTON and INGOLD), 919.

$C_{15}H_{13}OBr$ ω-Bromo-ω-benzylacetophenone (Stevens, Creighton, Gordon, and MacNicol), 3197.

$C_{15}H_{13}O_2N$ 3′-Hydroxy-*N*-phenylphthalimidine methyl ether (Rowe, Himmat, and Levin), 2561.

$C_{15}H_{13}O_2N_3$ *iso*Nitroso-derivative of substance $C_{15}H_{14}ON_2$ (Krishnamurti), 416.

$C_{15}H_{13}O_2Cl$ Benzoyl-3-chloro-*o*-4-xylenol (Hinkel, Ayling, and Bevan), 2531.

$C_{15}H_{13}O_5N_3$ 3:5-Dinitro-4-acetomethylamidodiphenyl (Bell), 2776.

$C_{15}H_{14}ON_2$ Substance, from aniline and benzoylacetonitrile (Krishnamurti), 416.

$C_{15}H_{14}O_6S$ 2:5-Dimethoxydiphenylsulphone-2′-carboxylic acid (Price and Smiles), 3157.

$C_{15}H_{15}N_3S$ Acetophenone δ-phenylthiosemicarbazone (Stephen and Wilson), 1422.

$C_{15}H_{16}O_3N_2$ Nitro-9-acetyl-3-methyltetrahydrocarbazole (Plant and Rosser), 2458.

$C_{15}H_{16}O_4S$ β-Phenoxyethyl *p*-toluenesulphonate (Peacock and Tha), 2305.

$C_{15}H_{17}ON$ 9-Acetyl-3-methyltetrahydrocarbazole (Plant and Rosser), 2458.

$C_{15}H_{17}O_2N$ 6-Acetyl-3-methyl-ψ-indoxyl*spirocyclo*pentane (Plant and Rosser), 2458.

$C_{15}H_{17}O_6N_3$ 5:5′-Dinitro-2′-piperidino-2-hydroxybenzophenone (Le Fèvre), 3250.

$C_{15}H_{17}O_6P$ αγ-Diphenoxy*iso*propyl phosphate, and its sodium salt (Boyd and Ladhams), 220.

$C_{15}H_{18}O_3N_2$ Ethyl 1-phenyl-3-methyl-5-pyrazone-4-β-propionate (Clemo and Welch), 2628.

Nitrodimethyl-ψ-indoxyl*spirocyclo*hexanes (Betts and Plant), 2073.

$C_{15}H_{19}ON$ Acetylhexahydroheptindole (Perkin and Plant), 2587.

3:3:4:4-Tetramethyl*cyclo*pentane-1:2-dione anil (Ingold and Shoppee), 396.

$C_{15}H_{19}O_3N$ 10:11-Dihydroxy-9-acetyl-3-methylhexahydrocarbazole (Plant and Rosser), 2458.

$C_{15}H_{20}O_2N_2$ Diacetyl-2:3:7-1:2:3:4-tetrahydroquinoxalines (Gibson, Nutland, and Simonsen), 111.

$C_{15}H_{21}ON$ αα*β*-Trimethyl-Δβ-pentenoic *p*-toluidide (Bardhan), 2616.

$C_{15}H_{21}O_3N$ 1-2′:4′-Dimethylanilino*cyclo*hexane-1-carboxylic acid (Betts and Plant), 2073.

Ethyl *trans*-decahydro-β-naphthylidenecyanoacetate (Vogel), 2026.

$C_{15}H_{21}O_2Cl$ *d*-β-Octyl chlorobenzoates (Rule, Hay, Numbers, and Paterson), 183.

$C_{15}H_{21}O_2Br$ *d*-β-Octyl *o*-bromobenzoate (Rule, Hay, Numbers, and Paterson), 183.

$C_{15}H_{21}O_2I$ *d*-β-Octyl *o*-iodobenzoate (Rule, Hay, Numbers, and Paterson), 183.

$C_{15}H_{21}O_3N_3$ Hydroxy-2:2:3:3-tetramethyl*cyclo*pentanone *p*-nitrophenylhydrazone (Shoppee), 1666.

$C_{15}H_{21}O_6N$ Ethyl 3-amino-1-methyl*dicyclo*pentane-2:4:5-tricarboxylate (Goss and Ingold), 1277.

$C_{15}H_{22}O_2N_2$ Oxylupanine (Clemo and Leitch), 1819.

$C_{15}H_{22}N_2S$ 1-*n*-Heptylamino-3-methylbenzthiazole (Hunter and Styles), 3027.

$C_{15}H_{23}ON$ *l*-Oximino-α-curcumene, and its hydrochloride (Rao and Simonsen), 2501.

$C_{15}H_{23}O_2N$ Ethyl α-*n*-butyl-Δ¹-*cyclo*hexenylcyanoacetate (McRae and Manske), 486.

Ethyl *r-trans*-dehydro-β-naphthylcyanoacetate (Vogel), 2026.

$C_{15}H_{24}ON_2$ Lupanine, and its salts (Clemo and Leitch), 1815.

*iso*Lupanine (Clemo and Leitch), 1819.

$C_{15}H_{24}O_3N_2$ Caryophyllene nitrosite, rotation dispersion and circular dichroism of (MITCHELL), 3258.

$C_{15}H_{24}N_2S$ *s*-*o*-Tolyl-*n*-heptylthiocarbamide (HUNTER and STYLES), 3026.

$C_{15}H_{25}ON_3$ Aromadendrone semicarbazone (BRIGGS and SHORT), 2528.

α-Methyl-α-Δ^1-pulegenylacetone semicarbazone (JUPP, KON, and LOCKTON), 1643.

$C_{15}H_{30}Cl_2Te_2$ Pentamethylene-αε-bis*cyclo*telluripentane 1:1′-dichloride (MORGAN and BURGESS), 325.

$C_{15}H_{30}Br_2Te_2$ Pentamethylene-αε-bis*cyclo*telluripentane 1:1′-dibromide (MORGAN and BURGESS), 326.

$C_{15}H_{30}Br_6Te_2$ Pentamethylene-αε-bis*cyclo*telluripentane 1:1′-bisperbromide (MORGAN and BURGESS), 327.

$C_{15}H_{30}I_2Te_2$ Pentamethylene-αε-bis*cyclo*telluripentane 1:1′-di-iodide (MORGAN and BURGESS), 328.

15 IV

$C_{15}H_{12}O_3N_2Cl_2$ 4-Methoxy*iso*phthalaldehydic acid 2:4-dichlorophenylhydrazone (CHATTAWAY and CALVERT), 2916.

$C_{15}H_{12}O_6N_2Cl$ αγ-Di-*p*-nitrophenoxy*iso*propyl chloride (BOYD and LADHAMS), 221.

$C_{15}H_{14}ONCl$ *p*-Chlorophenyl β-phenylethyl ketone (BURTON and INGOLD), 920.

Phenyl β-*p*-chlorophenylethyl ketoxime (BURTON and INGOLD), 919.

$C_{15}H_{15}ONS_2$ 2:4-Dimethylthiolbenzanilide (HODGSON and HANDLEY), 164.

$C_{15}H_{15}O_2NS$ 2-*p*-Toluenesulphonyldihydro*iso*indole (FENTON and INGOLD), 3295.

$C_{15}H_{15}O_2N_2Br_3$ 4-2′:4′:6′-Tribromobenzeneazo-5-hydroxy-2:2:3:3-tetramethyl*cyclo*pentenone (SHOPPEE), 2364.

$C_{15}H_{17}O_4N_2Cl$ Ethyl 6-chloronitrotetrahydrocarbazole-9-carboxylate (PLANT and ROSSER), 2463.

$C_{15}H_{16}O_2NCl$ Ethyl 6-chlorotetrahydrocarbazole-9-carboxylate (PLANT and ROSSER), 2463.

$C_{15}H_{17}O_4NS$ Ethyl α-naphthalenesulphonylalanines (COLLES and GIBSON), 108.

$C_{15}H_{17}O_5N_2Cl$ Ethyl 6-chloro-11-nitro-10-hydroxyhexahydrocarbazole-9-carboxylate (PLANT and ROSSER), 2464.

$C_{15}H_{18}O_4NCl$ Ethyl 6-chloro-10:11-dihydroxyhexahydrocarbazole-9-carboxylate (PLANT and ROSSER), 2464.

$C_{15}H_{21}N_2BrS$ 5-Bromo-1-*n*-heptylamino-3-methylbenzthiazole (HUNTER and STYLES), 3027.

$C_{15}H_{21}N_2Br_3S$ 5-Bromo-1-*n*-heptylamino-3-methylbenzthiazole hydrobromide (HUNTER and STYLES), 3027.

$C_{15}H_{22}N_2Br_6S$ *s*-*o*-Tolyl-*n*-heptylthiocarbamide hexabromide (HUNTER and STYLES), 3027.

$C_{15}H_{22}N_2BrS$ *s*-5-Bromo-*o*-tolyl-*n*-heptylthiocarbamide (HUNTER and STYLES), 3027.

$C_{15}H_{30}N_7Te_2Cr_2$ Pentamethylene-αε-bis*cyclo*telluripentane 1:1′-dichromate (MORGAN and BURGESS), 326.

C_{16} Group.

$C_{16}H_{12}O_5$ 3-Acetylpurpuroxanthin (PERKIN and STOREY), 238.

$C_{16}H_{12}O_5$ Anthrapurpurin 1:7-dimethyl ether (PERKIN and STOREY), 237.

Purpurin 2:4-dimethyl ether (PERKIN and STOREY), 238.

$C_{16}H_{12}N_2$ 3-Methyl-5:6-benz-4-carboline, and its salts (KERMACK and SLATER), 42.

Methylbenzcarbolines (KERMACK and SLATER), 795.

$C_{16}H_{13}N$ 1:2-Indolo(2:3)-3:4-dihydronaphthalene (TITLEY), 2577.

$_1H_{12}Cl$ 2-Chloro-9-ethylanthracene (BARNETT and WILTSHIRE), 1824.

$_1H_{14}O_5$ 2-Benzoyloxy-4:6-dimethoxybenzaldehyde (ROBERTSON, ROBINSON, and STRUTHERS), 1457.

$_1H_{14}O_6$ 6:6′-Dimethoxydiphenic acid, and its alkaloid salts (KENNER and TURNER), 2342.

$_1H_{16}O$ γ-Phenyl-α-*p*-tolylallyl alcohol (BURTON and INGOLD), 916.

$_1H_{16}O_2$ *l*-αβ-Diphenylethyl acetate (GERRARD and KENYON), 2565.

$_1H_{16}O_5$ *O*-Benzylsyringic acid (BRADLEY and ROBINSON), 1555.

$_1H_{16}N_2$ 1-Phenyl-4-aminomethyl-3:4-dihydro*iso*quinoline (JACKSON and KENNER), 1660.

$_1H_{17}N$ Hexahydro-αβ-naphthacarbazoles (OAKESHOTT and PLANT), 1844.

$_1H_{18}O_5$ Piperonylidene-ααβ-trimethyl-lævulic acid (BARDHAN), 2616.

$_1H_{18}S_2$ *s*-Di-*p*-tolylthiolethane (BELL and BENNETT), 3190.

$_1H_{20}O_3$ Benzoyloxy-2:2:3:3-tetramethyl*cyclo*pentanones (SHOPPEE), 1668.

$_1H_{20}O_6$ Ethyl phenylmethanetricarboxylate (FLÜRSCHEIM and HOLMES), 1612.

$_1H_{20}O_8$ Ethyl trimethoxybenzoylacetoxyacetate (BRADLEY and ROBINSON), 1531.

$_1H_{22}O_4$ Ethyl phenylenedipropionates (TITLEY), 2578, 2583.

l-β-Octyl hydrogen terephthalate (RULE, HAY, NUMBERS, and PATERSON), 183.

$_1H_{22}O_5$ Ethyl β-*p*-methoxyphenylglutarate (JACKSON and KENNER), 1660.

$_1H_{24}O_2$ *d*-β-Octyl toluates (RULE, HAY, NUMBERS, and PATERSON), 183.

$_1H_{26}O_2$ Luparol (CHAPMAN), 1305.

$_1H_{28}O_4$ *l*-Menthyl hydrogen adipate (RULE, HAY, and PAUL), 1358.

$_1H_{30}O_3$ *l*-Menthyl *n*-butoxyacetate (RULE, HAY, and PAUL), 1356.

16 III

$_1H_{10}O_4N_4$ 2-(2:4-Dinitrostyryl)quinoxaline (BENNETT and WILLIS), 1967.

$_1H_{11}O_2N_3$ Nitrostyrylquinoxalines (BENNETT and WILLIS), 1967.

$_1H_{11}O_2Cl$ 2-Chloro-9-anthranyl acetate (BARNETT and WILTSHIRE), 1824.

$_1H_{11}O_4N$ *r*- and *l*-Phthalimidophenylacetic acids (MCKENZIE and WALKER), 648.

$_1H_{12}ON_2$ 3-Keto-1-methyl-3:4-dihydro-5:6-benz-4-carboline (KERMACK and SLATER), 44.

$_1H_{12}O_4N_2$ 3-*o*-Nitrophenyl-1-methylindole-2-carboxylic acid, and its salts (KERMACK and PERKIN), 43.

$_1H_{12}O_4Cl_2$ Methyl 5:5′-dichlorodiphenyl-3:3′-dicarboxylate (MCALISTER and KENNER), 1916.

$_1H_{12}ClBr$ 2-Chloro-10-bromo-9-ethylanthracene (BARNETT and WILTSHIRE), 1824.

$_1H_{13}O_3N_3$ Acetamido-3-phenylphthalazones (ROWE and LEVIN), 2555; (ROWE, HIMMAT, and LEVIN), 2560.

$_1H_{13}O_2N_5$ Diketosuccinimide phenylosazone (CHATTAWAY and HUMPHREY), 1096.

$_1H_{13}O_2Cl$ Phenyl β-methoxy-*p*-chlorostyryl ketone (BENNETT and WILLIS), 1966.

$_1H_{13}O_4N$ α-Phenylallyl *p*-nitrobenzoate (BURTON and INGOLD), 914.

$_1H_{13}O_5N$ Benzyl *p*-nitrobenzoyloxymethyl ketone (BRADLEY and SCHWARZENBACH), 2906.

$_1H_{13}O_5N_3$ 1-Hydroxy-3-(3′-nitrophenyl)-1:3-dihydrophthalazine-4-acetic acid (ROWE, HIMMAT, and LEVIN), 2559.

$_1H_{13}O_6Cl$ Peonidin chloride (MURAKAMI and ROBINSON), 1539.

$_1H_{13}O_9N_3$ 2:4-Dinitrophenylopianic oxime (BRADY, BAKER, GOLDSTEIN, and HARRIS), 536.

$C_{16}H_{14}O_2N_2$ 8′-Acetamido-*N*-phenylphthalimidine (ROWE, HIMMAT, and LEVIN), 2561.

$C_{16}H_{14}O_2Cu$ Methyl cuprisalicylate (DOAK and PACKER), 2768.

$C_{16}H_{14}O_4S_2$ 2:2′-Dicarboxymethylthioldiphenyl (BARBER and SMILES), 1146.

$C_{16}H_{14}O_5N_2$ 5-Carboxy-2-methoxyphenylglyoxylic acid phenylhydrazone (CHATTAWAY and CALVET), 2917.

$C_{16}H_{14}O_7Cu_2$ Methyl basic hydroxycuprisalicylate (DOAK and PACKER), 2767.

$C_{16}H_{14}N_4As_2$ 2:2′-Dimethylarsenobenziminazoles (PHILLIPS), 3137.

$C_{16}H_{15}O_2N$ 3-Acetamido-4-methylbenzophenone (BLAKEY and SCARBOROUGH), 2492.

3′-Hydroxy-*N*-phenylphthalimidine ethyl ether (ROWE, HIMMAT, and LEVIN), 2561.

$C_{16}H_{15}O_3N_3$ *iso*Nitroso-derivative, and its silver salt, of substance $C_{16}H_{16}ON_2$ (KRISHNAMURTI), 416.

$C_{16}H_{15}O_4Cl$ *O*-Benzylsyringoyl chloride (BRADLEY and ROBINSON), 1555.

$C_{16}H_{16}ON_2$ Substance, from *p*-toluidine and benzoylacetonitrile (KRISHNAMURTI), 416.

$C_{16}H_{16}O_4N_2$ *p*-Dimethylaminobenzyl nitrobenzoate (CLEMO and SMITH), 2424.

$C_{16}H_{16}O_6S$ Methyl 2:5-dimethoxydiphenylsulphone-2′-carboxylate (PRICE and SMILES), 3157.

$C_{16}H_{17}ON$ Ethyl benzyl-*p*-toluoylacetate oxime (BURTON and INGOLD), 920.

Phenyl β-*p*-tolylethyl ketoxime (BURTON and INGOLD), 921.

$C_{16}H_{17}ON_3$ Phenyl β-phenylethyl ketone semicarbazone (SHOPPEE), 2571.

$C_{16}H_{17}O_2N$ *N*-Benzoyl-*d*-ψ-ephedrine, and its hydrochloride (SIRCAR), 53.

p-Dimethylaminobenzyl benzoate (CLEMO and SMITH), 2424.

$C_{16}H_{17}O_3N_3$ 1-Hydroxy-3-(3′-aminophenyl)tetrahydrophthalazine-4-acetic acid (ROWE, HIMMAT, and LEVIN), 2560.

$C_{16}H_{17}O_4N$ *O*-Benzylsyringamide (BRADLEY and ROBINSON), 1556.

$C_{16}H_{18}O_2Br_2$ *p*-Bromobenzyl derivative of 1-bromo-2:2:3:3-tetramethyl-[0,1,2]-*dicyclo*pentan-4-ol-5-one (INGOLD and SHOPPEE), 388.

$C_{16}H_{18}O_2S_2$ Dibenzylthiolethane disulphoxides (BELL and BENNETT), 3191.

Di-*p*-tolylthiolethane disulphoxides (BELL and BENNETT), 3191.

$C_{16}H_{18}O_4N_2$ Ethyl nitro-3-methyltetrahydrocarbazole-9-carboxylate (PLANT and ROSSER), 2459.

$C_{16}H_{18}O_6Cu$ Methyl cuprisalicylate dihydrate (DOAK and PACKER), 2766.

$C_{16}H_{18}O_6Ni$ Methyl nickelosalicylate dihydrate (DOAK and PACKER), 2768.

$C_{16}H_{19}O_2N$ Acetylmethyl-ψ-indoxyl*spirocyclo*hexanes (BETTS and PLANT), 2072.

Ethyl 3-methyltetrahydrocarbazole-9-carboxylate (PLANT and ROSSER), 2459.

$C_{16}H_{19}O_2Br$ *p*-Bromobenzyl derivative of 2:2:3:3-tetramethyl-[0,1,2]-*dicyclo*pentan-4-ol-5-one (INGOLD and SHOPPEE), 390.

$C_{16}H_{19}O_3N$ *p*-Nitrobenzoyloxy-2:2:3:3-tetramethyl*cyclo*pentanone (SHOPPEE), 1667.

$C_{16}H_{19}O_3N$ Ethyl *o*-nitrophenyl methanetricarboxylate (FLÜRSCHEIM and HOLMES), 1616.

$C_{16}H_{21}O_3N$ 1-Carboxy*cyclo*heptane-1-acetanilic acid (VOGEL), 2025.

Hydroxy-2:2:3:3-tetramethyl*cyclo*pentanone oxime (SHOPPEE), 1668.

*cyclo*Pentane-1-acetic-1-carboxylic *p*-toluidide (BARDHAN), 2600.

$C_{16}H_{21}O_4N$ Ethyl 10:11-dihydroxy-3-methylhexahydrocarbazole-9-carboxylate (PLANT and ROSSER), 2460.

$C_{16}H_{22}O_3S$ Bornyl benzenesulphonates, decomposition and hydrolysis of (PATTERSON and MCALPINE), 2464.

$C_{16}H_{24}O_5N_2$ β-*p*-Methoxyphenylglutaric diurethane (JACKSON and KENNER), 1660.

$C_{16}H_{25}O_5N_3$ Ethyl Δ^1-*cyclo*hexenylacetylmalonate semicarbazone (JUPP, KON, and LOCKTON), 1641.

$C_{16}H_{26}ON_2$ Methyl-lupanines, and their hydrochlorides (CLEMO and LEITCH), 1816.
$C_{16}H_{27}O_2N$ Ethyl α-cyano-α-*n*-butyl-Δ^{β}-nonenoate (MCRAE and MANSKE), 488.
$C_{16}H_{29}N_2I$ Deoxylupanine methiodide (CLEMO and LEITCH), 1819.
$C_{16}H_{34}O_2S$ Di-*n*-octylsulphone (FENTON and INGOLD), 3130.

16 IV

$C_{16}H_{12}O_4NCl$ *p*-Chlorocinnamyl alcohol *p*-nitrobenzoate (BURTON), 1655.
α-*p*-Chlorophenylallyl alcohol *p*-nitrobenzoate (BURTON), 1655.
$C_{16}H_{12}O_4N_2S$ 1-Benzenesulphonamido-8-nitronaphthalene (MILLS and ELLIOTT), 1298.
$C_{16}H_{12}O_4N_2As_2$ 3:3′-Dihydroxy-6:6′-arseno-1:4-benz*iso*oxazine (NEWBERY, PHILLIPS, and STICKINGS), 3056.
$C_{16}H_{13}O_7N_3S$ 1-3′-Nitrobenzeneazo-β-naphthaquinone-1-sulphonic acid, sodium salt (ROWE, HIMMAT, and LEVIN), 2558.
$C_{16}H_{14}O_4N_4As_2$ 3:3′-Diamino-3:3-dihydroxy-6:6′-arseno-1:4-benz*iso*oxazine (NEWBERY, PHILLIPS, and STICKINGS), 3060.
$C_{16}H_{14}O_6N_4S_2$ 3:3′-Diacetamido-4:4′-dinitrodiphenyl disulphide (HODGSON and HANDLEY), 164.
$C_{16}H_{15}O_2NS$ Benzoyl-2-methyl-1-methylenebenzthiazole (CLARK), 2315.
$C_{16}H_{15}O_5NHg$ Acetoxymercuriacetamidodiphenyl (BELL), 2777.
$C_{16}H_{16}O_2N_2S_2$ 2:2′-Diacetamidodiphenyl disulphide (CLARK), 2319.
$C_{16}H_{16}O_2N_2As_2$ 6:6′-Arseno-(2:3-dihydro-1:4-benz*iso*oxazine) (NEWBERY, PHILLIPS, and STICKINGS), 3064.
$C_{16}H_{16}O_4N_2As_2$ Diacetamidodihydroxyarsenobenzenes (BALABAN), 811.
$C_{16}H_{17}O_2NS$ 2-*p*-Toluenesulphonyl-1-methyldihydro*iso*indole (FENTON and INGOLD), 3296.
$C_{16}H_{17}O_4NS_2$ *m*-Carboxyphenylethylsulphine-*p*-toluenesulphonylimine, and its resolution (HOLLOWAY, KENYON, and PHILLIPS), 3004.
$C_{16}H_{18}O_2NI$ Camphoroiodophenylimides (SINGH, AHUJA, and LAL), 2414.
$C_{16}H_{18}O_4NBr$ *p*-Nitrobenzyl derivative of 1-bromo-2:2:3:3-tetramethyl-[0,1,2]-*dicyclo*pentan-4-ol-5-one (INGOLD and SHOPPEE), 388.
$C_{16}H_{20}O_3NI$ Iodocamphoranilic acids (SINGH, AHUJA, and LAL), 2413.
$C_{16}H_{20}O_6N_2Ni$ Methyl diamminenickelosalicylate (DOAK and PACKER), 2769.
$C_{16}H_{22}O_5NS$ Menthyl *p*-nitrobenzenesulphonate (BELL), 2777.
$C_{16}H_{24}O_5NCl$ Tetramethyl glucose *p*-chloroanilide (BAKER), 1982.
$C_{16}H_{24}O_5NBr$ Tetramethyl glucose *p*-bromoanilide (BAKER), 1982.
$C_{16}H_{32}O_6N_2As$ *m*-Nitrobenzoyl-γ-*n*-hexylaminopropylarsinic acid (GOUGH and KING), 2442.
$C_{16}H_{27}ON_2I$ Lupanine methiodide (CLEMO and LEITCH), 1816.

16 V

$C_{16}H_{13}O_4NCl_4S$ 2:4-Bisdichloromethyl-1:3-benzdioxin-6-sulphonanilide (CHATTAWAY and MORRIS), 3246.

C_{17} Group.

$C_{17}H_{18}O_4$ 4-Hydroxy-3:8-dimethoxyphenanthrene-5-carboxylactone (GULLAND and VIRDEN), 928.
$C_{17}H_{18}O_5$ 3-Acetylpurpuroxanthin 1-methyl ether (PERKIN and STOREY), 239.
$C_{17}H_{18}O_6$ 1-Acetylpurpurin 2-methyl ether (PERKIN and STOREY), 238.
2-Ethylcarbonatoalizarin (PERKIN and STOREY), 240.
$C_{17}H_{12}S_2$ 2-Phenyl*peri*naphtha-1:3-dithiane (PRICE and SMILES), 2374.
$C_{17}H_{14}O_2$ ω-3-Hydrindonylacetophenone (JACKSON and KENNER), 579.

$C_{17}H_{14}N_2$ 1:3-Dimethyl-5:6-benz-4-carboline (KERMACK and SLATER), 45.
3:4-Dimethyl-5:6-benz-4-ψ-carboline (KERMACK and SLATER), 796.
3-Ethyl-5:6-benz-4-carboline (KERMACK and SLATER), 42.
$C_{17}H_{15}O_2$ Benzoyl derivative of 4-phenyl-2-pyrrolidone (JACKSON and KENNER), 1859.
$C_{17}H_{15}Cl$ 2-Chloro-9-*n*-propylanthracene (BARNETT and WILTSHIRE), 1824.
$C_{17}H_{16}O_3$ Phenyl β:3-dimethoxystyryl ketone (BENNETT and WILLIS), 1967.
$C_{17}H_{16}O_5$ 2′:4′:6′-Trimethoxyphenylphthalide (LUND), 1573.
$C_{17}H_{16}O_6$ 2′:4′:6′-Trimethoxybenzoyl-*o*-benzoic acid (LUND), 1574.
$C_{17}H_{18}O_4$ 4-Benzyloxy-3:5-dimethylacetophenone (BRADLEY and ROBINSON), 1564.
$C_{17}H_{18}O_5$ Methyl *O*-benzylsyringate (BRADLEY and ROBINSON), 1555.
$C_{17}H_{20}O_2$ Benzoylcamphor, physical properties of (LOWRY, MACCONKEY, and BURGESS), 1333.
$C_{17}H_{20}N_2$ 1-(8′-Tetrahydropentindyl)-1-cyano*cyclo*pentane, and its picrate (PLANT and RIPPON), 1912.
$C_{17}H_{22}O_6$ Ethyl *p*-carbethoxybenzylmalonate (TITLEY), 2581.
$C_{17}H_{24}O_6$ Ethyl 3:3′-dimethoxydiphenylglutarate (JACKSON and KENNER), 1661.
$C_{17}H_{26}O_{10}$ 2:3:4:6-Tetra-acetyl β-*iso*propylglucoside (HICKINBOTTOM), 3146.
$C_{17}H_{30}O_4$ *l*-Menthyl hydrogen pimelate (RULE, HAY, and PAUL), 1358.
$C_{17}H_{31}N$ *l*-Dimethyldihydro-α-curcumenylamine (RAO and SIMONSEN), 2504.
$C_{17}H_{32}O_3$ *l*-Menthyl *n*-amyloxyacetate (RULE, HAY, and PAUL), 1356.

17 III

$C_{17}H_8O_3S$ 3:4-Naphthathioxanthone-1:2-quinone (PRICE and SMILES), 3159.
$C_{17}H_{10}O_5S$ 1:2-Naphthaquinone 2′-carboxyphenyl sulphoxide (PRICE and SMILES), 3159.
$C_{17}H_{11}O_2N_3$ 2-[Glyoxalinyl-4(5)]-5-naphthacinchoninic acid (HUBBALL and PYMAN), 26.
$C_{17}H_{11}O_4N_3$ 2-(2:4-Dinitrostyryl)-quinoline (BENNETT and WILLIS), 1973.
$C_{17}H_{11}O_6N_5$ 2-(2:4:6-Trinitrostyryl)-3-methylquinoxaline (BENNETT and WILLIS), 1970.
$C_{17}H_{12}OCl_2$ Dichlorostyryl ketones (HEILBRON and HILL), 2867.
$C_{17}H_{12}O_3Br_2$ 5:5′-Dibromo-2:2′-dihydroxydistyryl ketone (MCGOOKIN and SINCLAIR), 1173.
$C_{17}H_{12}O_3S$ *o*-Carboxyphenyl 2-hydroxy-α-naphthyl sulphide (PRICE and SMILES), 2863.
$C_{17}H_{12}O_4N_4$ 2-(2:4-Dinitrostyryl)-3-methylquinoxaline (BENNETT and WILLIS), 1970.
$C_{17}H_{12}O_7S$ 2:4-Diacetoxythioxanthone dioxide (PRICE and SMILES), 3158.
$C_{17}H_{13}OCl$ Chlorodistyryl ketones (HEILBRON and HILL), 2866.
$C_{17}H_{13}O_2N$ 3:3-Dimethoxythebenidine (GULLAND and VIRDEN), 927.
$C_{17}H_{14}O_3N_2$ 2-*m*-Nitrostyryl-3-methylquinoxaline (BENNETT and WILLIS), 1969.
$C_{17}H_{15}O_2N_3$ Diketosuccinanil *p*-tolylhydrazone (CHATTAWAY and HUMPHREY), 1098.
$C_{17}H_{14}O_6S$ 2:5-Diacetoxydiphenylsulphone-2′-carboxylic acid (PRICE and SMILES), 3157.
$C_{17}H_{15}O_2Cl$ Chlorohydroxy-β-phenylethyl styryl ketones (HEILBRON and HILL), 2866.
Phenylchlorophenylallyl acetates (BURTON and INGOLD), 918.
$C_{17}H_{15}O_4N$ α-3-Methylcinnamyl *p*-nitrobenzoate (BURTON), 1656.
4-Methylcinnamyl *p*-nitrobenzoate (BURTON and INGOLD), 915.
α-*m*-Tolylallyl *p*-nitrobenzoate (BURTON), 1656.
α-*p*-Tolylallyl *p*-nitrobenzoate (BURTON and INGOLD), 915.

$C_{17}H_{15}O_5N_3$ Methyl 1-hydroxy-3-(3′-nitrophenyl)-1:3-dihydrophthalazine-4-acetate (ROWE, HIMMAT, and LEVIN), 2559.

$C_{17}H_{15}O_6Cl$ 5:7:4′-Trihydroxy-3′:5′-dimethoxyflavylium chloride (BRADLEY and ROBINSON), 1566.

$C_{17}H_{15}O_7Cl$ Malvidin chloride (BRADLEY and ROBINSON), 1562.

$C_{17}H_{16}OS_2$ 2-Benzoyl-2-phenyl-1:3-dithian (CHIVERS and SMILES), 701.

$C_{17}H_{16}O_3N_2$ ω-3-Hydrindonylacetophenone dioxime (JACKSON and KENNER), 579.

$C_{17}H_{16}O_2Br_2$ αγ-Diphenylallyl bromides (BURTON and INGOLD), 916.

$C_{17}H_{16}O_3N_2$ 3-Hydroxy-2′:5′-dimethoxy-2-benzylquinoxaline (GULLAND and VIRDEN), 1482.

$C_{17}H_{16}O_4N_2$ ω-Diazo-4-benzyloxy-3:5-dimethoxyacetophenone (BRADLEY and ROBINSON), 1560.

$C_{17}H_{17}ON$ Propionylacetophenoneanil (LOVETT and ROBERTS), 1977.

$C_{17}H_{17}O_3N_3$ Propionylacetophenone *p*-nitrophenylhydrazone (LOVETT and ROBERTS), 1977.

$C_{17}H_{17}O_5N$ *iso*Nitroso-4-benzyloxy-3:5-dimethoxyacetophenone (BRADLEY and ROBINSON), 1565.

$C_{17}H_{17}O_5N_3$ 5-Nitro-2-ethoxy-*p*-tolylglyoxylic acid phenylhydrazone (CHATTAWAY and CALVET), 1093.

$C_{17}H_{18}ON_2$ Substance, from *m*-4-xylidine and benzoylacetonitrile (KRISHNAMURTI), 416.

$C_{17}H_{19}ON$ ω-Dimethylamino-ω-benzylacetophenone, and its picrate (STEVENS, CREIGHTON, GORDON, and MACNICOL), 3196.

$C_{17}H_{20}O_4S_4$ Propane αγ-di-*p*-toluenethiolsulphonate (CHIVERS and SMILES), 700.

$C_{17}H_{20}O_6S_2$ Trimethylene glycol di-*p*-toluenesulphonate (GOUGH and KING), 2446.

$C_{17}H_{21}O_2N$ 7-Acetyl-8:10-dimethyl-ψ-indoxyl*spirocyclo*hexane (BETTS and PLANT), 2073.

$C_{17}H_{21}O_6Cl$ Ethyl chloro-*p*-carbethoxybenzylmalonate (TITLEY), 2581.

$C_{17}H_{21}O_6P$ Ditolyloxy*iso*propyl phosphates (BOYD and LADHAMS), 219.

$C_{17}H_{22}ON_2$ 1-(8′-Tetrahydropentindyl)*cyclo*pentane-1-carboxyamide (PLANT and RIPPON), 1912.

$C_{17}H_{22}OSn$ Phenylbenzyl-*n*-butylstannic hydroxide, and its salts (KIPPING), 2371.

$C_{17}H_{22}O_3N$ Atropine, spontaneous resolution of sulphate of (ANDERSON and HILL), 993.

β-*cyclo*Hexylglutaranilic acid (SIRCAR), 56.

$C_{17}H_{24}ON_2$ 3:3:4:4-Tetramethyl*cyclo*pentane-1:2-dione *p*-dimethylanil (INGOLD and SHOPPEE), 396.

$C_{17}H_{27}O_5N$ Tetramethyl glucose *p*-toluidide (BAKER), 1982.

$C_{17}H_{27}O_6N$ Tetramethyl glucose *p*-anisidide (BAKER), 1982.

$C_{17}H_{29}ON$ Acetyl derivative of *l*-dihydro-α-curcumenylamine (RAO and SIMONSEN), 2503.

$C_{17}H_{29}O_4N$ *l*-Dihydro-α-curcumenylamine (RAO and SIMONSEN), 2502.

17 IV

$C_{17}H_{13}O_2N_2Cl_6$ 6-*p*-Tolueneazo-2:4-bistrichloromethyl-1:3-benzdioxin (CHATTAWAY and CALVET), 1092.

$C_{17}H_{16}O_4N_2S$ 5:6-Benz-4-carboline methosulphate (KERMACK and SLATER), 795.

$C_{17}H_{20}ONBr$ Phenacylbenzyldimethylammonium bromide (STEVENS, CREIGHTON, GORDON, and MACNICOL), 3196.

$C_{17}H_{24}ON_2S$ Acetyl derivative of 1-*n*-heptylamino-3-methylbenzthiazole (HUNTER and STYLES), 3027.
$C_{17}H_{30}ON_2I$ Methyl-lupanine methiodides (CLEMO and LEITCH), 1817.
$C_{17}H_{30}O_5N_2S$ Lupanine methosulphate (CLEMO and LEITCH), 1816.

C_{18} Group.

$C_{18}H_{12}O_7$ Diacetylanthrapurpurins (PERKIN and STOREY), 235.
$C_{18}H_{12}N_2$ 3:4′-Diquinolyl, and its picrate (MILLS and ORDISH), 85.
$C_{18}H_{14}O_6$ 1-Acetylpurpurin 2:4-dimethyl ether (PERKIN and STOREY), 238.
Ethylcarbonatoalizarin methyl ethers (PERKIN and STOREY), 240.
$C_{18}H_{15}N$ 2-Styryl-3-methylquinoline (BENNETT and WILLIS), 1973.
$C_{18}H_{16}O_4$ 5-Aldehydo-3:4:8-trimethoxyphenanthrene (GULLAND and VIRDEN), 926.
Truxinic acid, synthesis of (VOGEL), 1021.
$C_{18}H_{16}O_5$ Ethyl benzoylbenzoyloxyacetate (BRADLEY and ROBINSON), 1548.
5:7:4′-Trimethoxy*iso*flavone (BAKER and ROBINSON), 3117.
$C_{18}H_{16}O_8$ Irigenin (BAKER), 1022.
$C_{18}H_{16}N_2$ *NN′*-Diphenyl-*o*-phenylenediamine (GIBSON and JOHNSON), 1988.
$C_{18}H_{18}O_2$ Phenyltolylallyl acetates (BURTON and INGOLD), 916.
$C_{18}H_{18}O_4$ 3:4:5:8-Tetramethoxyphenanthrene, and its picrate (GULLAND and VIRDEN), 1486.
$C_{18}H_{18}O_6$ ω-Benzoyloxy-3:4:5-trimethoxyacetophenone (BRADLEY and ROBINSON), 1550.
Methyl 6:6′-dimethoxydiphenate (KENNER and TURNER), 2341.
$C_{18}H_{22}O_5$ *d*-Carene-β-glycol hydrogen phthalate (PILLAY and SIMONSEN), 362.
$C_{18}H_{23}N_3$ 1-(9′-Hexahydrocarbazyl)-1-cyano*cyclo*pentane (PLANT and RIPPON), 1909.
$C_{18}H_{24}O_6$ Ethyl carbethoxybenzylmethylmalonate (TITLEY), 2582.
$C_{18}H_{26}O_2$ 2-Hydroxystyryl nonyl ketone (HEILBRON and IRVING), 2326.
$C_{18}H_{32}O_4$ *l*-Menthyl hydrogen suberate (RULE, HAY, and PAUL), 1358.
$C_{18}H_{34}O_3$ *l*-Menthyl *n*-hexyloxyacetate (RULE, HAY, and PAUL), 1356.

18 III

$C_{18}H_{13}O_4N$ 2-Nitrostyryl-3-methylchromones (NISBET), 3122.
$C_{18}H_{13}O_4N_3$ 2-(2:4-Dinitrostyryl)methylquinolines (BENNETT and WILLIS), 1973.
$C_{18}H_{14}O_2N_2$ 2-Methylenedioxystyryl-3-methylquinoxaline (BENNETT and WILLIS), 1968.
$C_{18}H_{15}O_2N_3$ 2-*m*-Nitrostyryl-3:6-dimethylquinoxaline (BENNETT and WILLIS), 1972.
$C_{18}H_{15}O_3N$ 3:4:8-Trimethoxy-5-cyanophenanthrene (GULLAND and VIRDEN), 927.
$C_{18}H_{16}ON_2$ 2-Methoxystyryl-3-methylquinoxalines (BENNETT and WILLIS), 1969.
$C_{18}H_{16}O_2N_2$ Nitroacetyltetrahydro-α′β′-naphthacarbazole (OAKESHOTT and PLANT), 1846.
$C_{18}H_{17}ON$ Acetyltetrahydronaphthacarbazoles (OAKESHOTT and PLANT), 1843.
8-Benzoyltetrahydropentindole (PLANT and RIPPON), 1911.
$C_{18}H_{17}O_3Cl$ Ethyl benzyl-*p*-chlorobenzoylacetate (BURTON and INGOLD), 920.
Ethyl *p*-chlorobenzylbenzoylacetate (BURTON and INGOLD), 919.
$C_{18}H_{17}O_3Cl$ 5-Hydroxy-4′-methoxy-6:8-dimethylflavylium chloride (ROBERTSON, ROBINSON, and STRUTHERS), 1458.
$C_{18}H_{17}O_4N$ 5-Aldehydo-3:4:8-trimethoxyphenanthrene oxime (GULLAND and VIRDEN), 927.
$C_{18}H_{17}O_5N$ α-Benzamido-2:5-dimethoxycinnamic acid (GULLAND and VIRDEN), 1481.

$C_{18}H_{17}O_5N_3$ Ethyl 1-hydroxy-3-(3′-nitrophenyl)-1:3-dihydrophthalazine-4-acetate (ROWE, HIMMAT, and LEVIN), 2559.

$C_{18}H_{17}O_6Cl$ 5:7-Dihydroxy-3:3′:5′-trimethoxyflavylium chloride (ROBERTSON, ROBINSON, and SUGIURA), 1536.

$C_{18}H_{17}O_7Cl$ 3:5:7-Trihydroxy-3′:4′:5′-trimethoxyflavylium chloride (BRADLEY and ROBINSON), 1551.

$C_{18}H_{18}O_2N_2$ 3-Hydroxy-2-(6′-methoxy-3′-ethylbenzyl)quinoxaline (GULLAND and VIRDEN), 931.

$C_{18}H_{18}O_4N_2$ Methyl 3:4:8-trimethoxyphenanthrene-5-carboxylate hydrazide (GULLAND and VIRDEN), 926.

2′-Nitro-6:7-dimethoxy-1-benzyl-3:4-dihydro*iso*quinoline, and its hydrochloride (GULLAND and HAWORTH), 586.

$C_{18}H_{19}ON$ Acetylhexahydro-$\alpha\beta$-naphthacarbazoles (OAKESHOTT and PLANT), 1844.

$C_{18}H_{19}O_2N$ Hydroxyphenylthymylacetonitriles (BELL and HENRY), 2225.

$C_{18}H_{19}O_3N$ Catechylthymylacetonitrile (BELL and HENRY), 2226.

$C_{18}H_{19}O_4N_3$ 1-Hydroxy-3-(3′-acetamidophenyl)tetrahydrophthalazine-4-acetic acid (ROWE, HIMMAT, and LEVIN), 2560.

$C_{18}H_{20}O_5N_2$ 2′-Nitrophenylaceto-β-3:4-dimethoxyphenylethylamide (GULLAND and HAWORTH), 585.

$C_{18}H_{20}O_8N_4$ Dinitro-*NN′*-dicarbethoxybenzidines (LE FÈVRE and TURNER), 252.

$C_{18}H_{21}O_2N$ 1-(9′-Tetrahydrocarbazyl)*cyclo*pentane-1-carboxylic acid (PLANT and RIPPON), 1910.

$C_{18}H_{21}O_6N_3$ 2-Nitro-*NN′*-dicarbethoxybenzidine (LE FÈVRE and TURNER), 252.

$C_{18}H_{23}O_4N_2$ 4-*p*-Carbethoxybenzeneazo-5-hydroxy-2:2:3:3-tetramethyl-Δ^4-*cyclo*pentenone (SHOPPEE), 2364.

$C_{18}H_{24}ON_2$ 1-(9′-Hexahydrocarbazyl)*cyclo*pentane-1-carboxyamide (PLANT and RIPPON), 1910.

$C_{18}H_{25}OCl$ Chlorostyryl nonyl ketones (HEILBRON and IRVING), 2326.

$C_{18}H_{24}NI$ *l*-Dihydro-α-curoumenyltrimethylammonium iodide (RAO and SIMONSEN), 2503.

18 IV

$C_{18}H_9O_2Br_7Se$ Tri-3:5-dibromotri-4-hydroxytriphenylselenonium bromide (MORGAN and BURSTALL), 3266.

$C_{18}H_{12}ONBr$ Phenacyl-β-phenylethyldimethylammonium bromide (STEVENS, CREIGHTON, GORDON, and MACNICOL), 3195.

$C_{18}H_{12}O_3Br_4Se$ Tri-3-bromotri-4-hydroxytriphenylselenonium bromide (MORGAN and BURSTALL), 3265.

$C_{18}H_{12}N_2Cl_2As_2$ Dichlorotetrahydro*iso*benzarsazinephenarsazines (GIBSON and JOHNSON), 2211.

$C_{18}H_{12}N_2Br_2As_2$ Dibromotetrahydrobenzarsazinephenarsazines (GIBSON and JOHNSON), 2213.

$C_{18}H_{12}N_2I_2As_2$ Di-iodotetrahydrobenzarsazinephenarsazine (GIBSON and JOHNSON), 2213.

$C_{18}H_{14}O_4N_2As_2$ Benzarsazinicphenarsazinic acids, and their sodium salts (GIBSON and JOHNSON), 2212.

$C_{18}H_{14}O_6N_2S$ *N*-Benzenesulphonyl-8-nitro-1-naphthylglycine, and its brucine salts (MILLS and ELLIOTT), 1299.

$C_{18}H_{15}O_3ClSe$ Trihydroxytriphenylselenonium chlorides (MORGAN and BURSTALL), 3266.

$C_{18}H_{15}O_6NSe$ Tri-4-hydroxytriphenylselenonium nitrate (MORGAN and BURSTALL), 3265.

$C_{18}H_{15}O_6ClSe$ Tri-2:4-dihydroxytriphenylselenonium chloride (MORGAN and BURSTALL), 3269.

$C_{18}H_{16}ON_4S$ Dibenzylidene derivative of 3-amino-2:4-diketo-5-methyltetrahydrothiazole 2-hydrazone (STEPHEN and WILSON), 1419.

$C_{18}H_{16}O_4N_2AS_2$ 3:3'-Dihydroxy-8:8'-dimethyl-6:6'-arseno-1:4-benz*iso*oxazine(NEWBERY, PHILLIPS, and STICKINGS), 3061.

$C_{18}H_{16}O_4N_2S$ 1:4-Dimethyl-5:6-benz-4-carbolinium methyl sulphate (KERMACK and SLATER), 795.

3-Methyl-5:6-benz-4-carboline methosulphate (KERMACK and SLATER), 795.

$C_{18}H_{15}O_6N_2AS_2$ 1:3-Phenylenediaminodi-*o*-phenylarsinic acid (GIBSON and JOHNSON), 2211.

$C_{18}H_{20}O_2N_2S_2$ 2:2'-Dipropionamidodiphenyl disulphide (CLARK), 2319.

$C_{18}H_{20}O_2N_2Se_2$ 2:2'-Diacetmethylamidodiphenyl diselenide (CLARK), 2317.

$C_{18}H_{20}O_4N_2S_2$ Diacetamido-5:5'-dimethoxydiphenyl disulphides (HODGSON and HANDLEY), 626.

$C_{18}H_{20}O_4N_2AS_2$ 3:3'-Diacetamido-4:4'-dihydroxy-5:5'-dimethylarsenobenzene(NEWBERY, PHILLIPS, and STICKINGS), 3061.

$C_{18}H_{22}ONBr$ ω-Dimethylamino-ω-benzylacetophenone methobromide (STEVENS, CREIGHTON, GORDON, and MACNICOL), 3197.

$C_{18}H_{22}ONI$ Phenacylphenyldiethylammonium iodide (STEVENS, CREIGHTON, GORDON, and MACNICOL), 3195.

$C_{18}H_{22}O_4N_2S_4$ Dithianbis-*p*-toluenesulphonylimines (BELL and BENNETT), 92.

$C_{18}H_{44}O_{12}N_9Co_2$ Hexa-allylamineperoxodihydroxodicobalt trinitrate (BUCKNALL and WARDLAW), 2651.

18 V

$C_{18}H_{44}O_4N_6Cl_3Co_2$ Hexa-allylamineperoxodihydroxodicobalt trichloride (BUCKNALL and WARDLAW), 2649.

C_{19} Group.

$C_{19}H_{15}$ Triphenylmethyl, photodecomposition of (BOWDEN and JONES), 1149.

19 II

$C_{19}H_{14}O_7$ Diacetylanthrapurpurin methyl ethers (PERKIN and STOREY), 235.

$C_{19}H_{14}S_2$ Benzaldehydediphenylene-2:2'-mercaptal (BARBER and SMILES), 1146.

$C_{19}H_{16}O_7$ Trimethoxy*iso*flavonecarboxylic acid (BAKER and ROBINSON), 3117.

$C_{19}H_{18}O_2$ 4-Acetonyl-3-phenyl-2-methyl-1:4-benzopyran (HILL), 258.

4-Phenacyl-2:3-dimethyl-1:4-benzopyran (HILL), 258.

$C_{19}H_{18}O_6$ 2:3:5:6-Tetramethoxyphenanthrene-8-carboxylic acid (BARGER and SILBERSCHMIDT), 2922.

3:4:5:8-Tetramethoxyphenanthrene-9-carboxylic acid (GULLAND and VIRDEN), 1486.

Trimethylbrazilone (PERKIN, RÂY, and ROBINSON), 1510.

$C_{19}H_{20}O_3$ Ethyl benzyl-*p*-toluoylacetate (BURTON and INGOLD), 920.

Ethyl *p*-methylbenzylbenzoylacetate (BURTON and INGOLD), 920.

3:4:8-Trimethoxy-5-ethylphenanthrene (GULLAND and VIRDEN), 933.

$C_{19}H_{20}O_4$ Dihydrodeoxytrimethylbrazilone (PERKIN, RÂY, and ROBINSON), 1510.

$C_{19}H_{20}O_6$ ω-Acetoxy-4-benzyloxy-3:5-dimethoxyacetophenone (BRADLEY and ROBINSON), 1560.

Trimethyldihydrobrazilone (PERKIN, RÂY, and ROBINSON), 1512.

$C_{19}H_{22}O_4$ Tolylthymylacetic acid (BELL and HENRY), 2225.

$C_{19}H_{26}O_7$ Ethyl *p*-methoxyphenylpropane-$\alpha\alpha\gamma$-tricarboxylate (JACKSON and KENNER), 1660.

$C_{19}H_{34}O_4$ *l*-Menthyl hydrogen azelate (RULE, HAY, and PAUL), 1358.

$C_{19}H_{36}O_2$ Methyl elaidate, oxidation of (HILDITCH and LEA), 1576.

Methyl oleate, oxidation of (HILDITCH and LEA), 1576.

$C_{19}H_{36}O_3$ *l*-Menthyl *n*-heptyloxyacetate (RULE, HAY, and PAUL), 1856.
$C_{19}H_{40}O$ Octadecyl methyl ether (HEILBRON and OWENS), 1946.

19 III

$C_{19}H_{12}O_2N_2$ Diquinolyl-2-carboxylic acids (MILLS and ORDISH), 85.
$C_{19}H_{12}O_2Br_2$ 4:5-Dibromo-3-benzoyloxydiphenyl (HINKEL and HEY), 1203.
$C_{19}H_{13}O_2Br$ 5-Bromo-3-benzoyloxydiphenyl (HINKEL and HEY), 1203.
$C_{19}H_{15}O_4N$ 5-Keto-2-phenyl-4-(2′:5′-dimethoxybenzylidene)-4:5-dihydro-oxazole (GULLAND and VIRDEN), 1481.
$C_{19}H_{15}O_4N_3$ 6-Benzoylamino-3:4-dihydrocoumarin-4-cyanoacetamide (SESHADRI), 172.
$C_{19}H_{17}O_3N$ 5-Keto-2-phenyl-4-(6′-methoxy-3′-ethylbenzylidene)-4:5-dihydro-oxazole (GULLAND and VIRDEN), 930.
$C_{19}H_{18}ON_2$ 2-*p*-Methoxystyryl-3:6-dimethylquinoxaline (BENNETT and WILLIS), 1971.
$C_{19}H_{18}O_6N_2$ 2′-Nitro-3′:4′-dimethoxy-6:7-methylenedioxy-1-benzyl-3:4-dihydro-*iso*quinoline, and its salts (GULLAND and HAWORTH), 1134.
2′-Nitro-6:3′:4′-trimethoxy-1-benzoyl-3:4-dihydro*iso*quinoline (GULLAND and HAWORTH), 2086.
$C_{19}H_{19}ON$ Benzoylhexahydroquinidenes (PERKIN and PLANT), 643.
$C_{19}H_{19}O_4N_3$ 5-Aldehydo-3:4:8-trimethoxyphenanthrene semicarbazone (GULLAND and VIRDEN), 926.
$C_{19}H_{19}O_5N$ 7:8:2′:5′-Tetramethoxy-3-phenylcarbostyril (GULLAND and VIRDEN), 1484.
$C_{19}H_{19}O_6N$ 2-Nitro-3:4:2′:5′-tetramethoxy-α-phenylcinnamic acids (GULLAND and VIRDEN), 1482.
$C_{19}H_{20}O_2N_6$ ω-3-Hydrindoxylacetophenone disemicarbazone (JACKSON and KENNER), 579.
$C_{19}H_{20}O_6N_2$ 2′-Nitro-6:3′:4′-trimethoxy-1-benzyl-3:4-dihydro*iso*quinoline, and its salts (GULLAND and HAWORTH), 2085.
$C_{19}H_{20}O_7N_2$ 2′-Nitro-3′:4′-dimethoxyphenylaceto-β-3:4-methylenedioxyphenylethylamide (GULLAND and HAWORTH), 1134.
$C_{19}H_{21}O_3N$ Anisylthymylacetonitrile (BELL and HENRY), 2225.
5:6-Dimethoxyaporphine, and its hydrochloride (GULLAND and HAWORTH), 590.
Tolylthymylacetonitrile (BELL and HENRY), 2225.
$C_{19}H_{21}O_3N_3$ 2-(4′:5′-Dimethoxy-2′-β-methylaminoethyl)phenyl-3-oximinoindole (GULLAND and HAWORTH), 588.
$C_{19}H_{21}O_4N$ Laurotetanine, constitution of (BARGER and SILBERSCHMIDT), 2919.
$C_{19}H_{21}O_6N$ 2-Amino-3:4:2′:5′-tetramethoxy-α-phenylcinnamic acids (GULLAND and VIRDEN), 1483.
$C_{19}H_{22}O_2N_2$ 2-(4′:5′-Dimethoxy-2′-β-methylaminoethyl)phenylindole, and its hydrochloride (GULLAND and HAWORTH), 587.
$C_{19}H_{22}O_6N_2$ 2′-Nitro-3′:4′-dimethoxyphenylaceto-β-3-methoxyphenylethylamide (GULLAND and HAWORTH), 2084.
$C_{19}H_{23}O_2N$ Diethylaminoethyl diphenylcarboxylates, and their hydrochlorides (BELL), 3248.
$C_{19}H_{23}O_3N$ Tolylthymylacetamide (BELL and HENRY), 2225.
$C_{19}H_{24}O_4N_2$ 2′-Amino-6:7-dimethoxy-1-benzyl-2-methyltetrahydro*iso*quinoline, and its hydrochloride (GULLAND and HAWORTH), 589.
2-(4′:5-Dimethoxy-2′-β-methylaminoethyl)phenyldihydroindole, and its hydrochloride (GULLAND and HAWORTH), 589.

19 IV

$C_{19}H_{12}O_2N_2I_2$ 3:5-Di-iodo-4-benzoyloxyazobenzene (HUNTER and BARNES), 2067.

$C_{19}H_{13}O_2N_2Br$ 3-Bromo-4-benzoyloxybenzene (HUNTER and BARNES), 2064.
$C_{19}H_{13}O_2N_2I$ 3-Iodo-4-benzoyloxyazobenzene (HUNTER and BARNES), 2065.
$C_{19}H_{14}O_8N_4S$ 3:5:4′-Trinitro-2-*p*-toluenesulphonamidodiphenyl (BELL), 2775.
$C_{19}H_{15}O_3N_2Cl$ 6-Chloronitro-9-benzoyltetrahydrocarbazole (PLANT and ROSSER), 2463.
$C_{19}H_{15}O_6N_3S$ 3:5-Dinitro-*p*-toluenesulphonamidodiphenyls (BELL), 2774.
$C_{19}H_{16}ONCl$ 6-Chloro-9-benzoyltetrahydrocarbazole (PLANT and ROSSER), 2463.
$C_{19}H_{16}O_4N_2S$ Nitro-2-*p*-toluenesulphonamidodiphenyls (BELL), 2774.
$C_{19}H_{17}O_2NS$ 2-*p*-Toluenesulphonamidodiphenyl (BELL), 2774.
$C_{19}H_{17}O_4N_2Cl$ 6-Chloro-11-nitro-10-hydroxy-9-benzoylhexahydrocarbazole (PLANT and ROSSER), 2463.
$C_{19}H_{17}N_2IS$ 1′:2-Dimethylthio-ψ-cyanine iodide (HAMER), 213.
$C_{19}H_{17}N_2ISe_2$ 2:2′-Dimethylselenocarbocyanine iodide (CLARK), 2318.
$C_{19}H_{18}ON_4S$ Dibenzylidene derivative of 3-amino-2:4-diketo-5-ethyltetrahydrothiazole 2-hydrazone (STEPHEN and WILSON), 1419.
$C_{19}H_{20}O_3NI$ Hydrohydrastinine phenacyloiodide (STEVENS, CREIGHTON, GORDON, and MACNICOL), 3196.
$C_{19}H_{20}O_4N_2S$ 3-Ethyl-5:6-benz-4-carboline methosulphate (KERMACK and SLATER), 797.
1:3:4-Trimethyl-5:6-benz-4-carbolinium methyl sulphate (KERMACK and SLATER), 796.
$C_{19}H_{21}O_4N_2I$ 2′-Nitro-6:7-dimethoxy-1-benzyl-3:4-dihydro*iso*quinoline methiodide (GULLAND and HAWORTH), 586.
$C_{19}H_{26}O_5Br_2S$ Bromocamphorsulphonyl derivative of 1-bromo-2:2:3:3-tetramethyl-[0, 1, 2]-*dicyclo*pentan-4-ol-5-one (INGOLD and SHOPPEE), 387.
$C_{19}H_{29}ON_2Cl$ 2-Chlorostyryl nonyl ketone semicarbazone (HEILBRON and IRVING), 2326.

19 V

$C_{19}H_{12}O_2N_2ClBr$ 3-Chloro-5-bromo-4-benzoyloxyazobenzene (HUNTER and BARNES), 2065.
$C_{19}H_{12}O_2N_2ClI$ 3-Chloro-5-iodo-4-benzoyloxyazobenzene (HUNTER and BARNES), 2065.
$C_{19}H_{12}O_2N_2BrI$ 3-Bromo-5-iodo-4-benzoyloxyazobenzene (HUNTER and BARNES), 2066.
$C_{19}H_{16}O_2NBrS$ 3-Bromo-4-*p*-toluenesulphonamidodiphenyl (BELL), 2778.

C_{20} Group.

$C_{20}H_{32}$ Dipinene, oxidation of (BRIGGS and SHORT), 3118.

20 II

$C_{20}H_{10}O_2$ 1:1′-Dinaphthylene 2:8′:2′:8-dioxide (CLEMO and SPENCE), 2815.
$C_{20}H_{10}O_2$ *o*-Dinaphthaquinone oxide (CLEMO and SPENCE), 2817.
*iso*Dinaphthaquinone oxide (CLEMO and SPENCE), 2817.
$C_{20}H_{12}O$ 1:1′-Dinaphthylene 2:2′-oxide (CLEMO and SPENCE), 2815.
*iso*Dinaphthylene oxide (CLEMO and SPENCE), 2816.
$C_{20}H_{12}O_4$ Dihydroxydinaphthaquinone (CLEMO and SPENCE), 2817.
$C_{20}H_{12}S$ 1:1′-Dinaphthylene 2:2′-sulphide (BARBER and SMILES), 1148.
$C_{20}H_{12}S_2$ 1:1′-Dinaphthylene 2:2′-disulphide (BARBER and SMILES), 1148.
$C_{20}H_{14}O_2$ β-Dinaphthol (CLEMO and SPENCE), 2815.
$C_{20}H_{14}O_4$ Phenolphthalein, constitution of (LUND), 1569.
2-Phenyl-6-piperonylidenemethyl-4-pyrone, and its salts (GIBSON and SIMONSEN), 2311.
$C_{20}H_{16}O$ Diethylcarbonatoalizarin (PERKIN and STOREY), 240.

$C_{20}H_{16}O_9$ 2:3-Diethylcarbonatoanthragallol (PERKIN and STOREY), 242.
2:7-Diethylcarbonatoanthrapurpurin (PERKIN and STOREY), 236.
$C_{20}H_{17}N$ 1:3-Diphenyldihydro*iso*indole, and its salts (BOYD and LADHAMS), 2093.
$C_{20}H_{18}O_8$ Methyl dibenzoyltartrate (FINDLAY and CAMPBELL), 1773.
r-$\beta\gamma$-Diphenylbutane-$\alpha\alpha\delta\delta$-tetracarboxylic acid (VOGEL), 1019.
$C_{20}H_{20}O_4$ Dimethyl truxinate (VOGEL), 1021.
2:3:5:6-Tetramethoxy-8-vinylphenanthrene (BARGER and SILBERSCHMIDT), 2922.
$C_{20}H_{20}O_5$ 3:4:8-Trimethoxy-5-ethylphenanthrene-9-carboxylic acid (GULLAND and VIRDEN), 933.
$C_{20}H_{20}O_8$ Irigenin dimethyl ethers (BAKER), 1031.
$C_{20}H_{22}O_6$ Ethyl *O*-benzylsyringoylacetate, and its copper salt (BRADLEY and ROBINSON), 1557.
$C_{20}H_{24}N_4$ *pp'*-Tetramethyldiaminodiphenyl[glyoxalinyl-4(5)-]methane (HUBBALL and PYMAN), 26.
$C_{20}H_{28}O_8$ Ethyl β-3:4-dimethoxyphenylpropane-$\alpha\alpha\gamma$-tricarboxylate (JACKSON and KENNER), 1661.
$C_{20}H_{28}Sn$ Dibenzylethyl-*n*-butylstannane (KIPPING), 2372.
$C_{20}H_{30}O_3$ 3:4-Dimethoxystyryl nonyl ketone (HEILBRON and IRVING), 2324.
$C_{20}H_{36}O_4$ *l*-Menthyl hydrogen sebacate (RULE, HAY, and PAUL), 1358.
$C_{20}H_{38}O_3$ *l*-Menthyl *n*-octyloxyacetate (RULE, HAY, and PAUL), 1357.

20 III

$C_{20}H_{10}OBr_2$ Dibromo*iso*dinaphthylene oxide (CLEMO and SPENCE), 2816.
$C_{20}H_{12}O_4N_4$ 2:3-Di-*p*-nitrophenylquinoxaline (CHATTAWAY and COULSON), 1363.
2-*m*-Nitrophenyl-3-nitrophenylquinoxalines (CHATTAWAY and COULSON), 1087.
$C_{20}H_{12}I_2S_2$ Di-1-iodo-2-naphthyl disulphide (BARBER and SMILES), 1145.
$C_{20}H_{13}O_2N_3$ 2-*p*-Nitrophenyl-3-phenylquinoxaline (CHATTAWAY and COULSON), 1084.
$C_{20}H_{13}O_4Br$ Bromo-2-phenyl-6-piperonylidenemethyl-4-pyrone (GIBSON and SIMONSEN), 2312.
$C_{20}H_{14}O_2N_2$ 2:3-Di(β-furylvinyl)quinoxaline (BENNETT and WILLIS), 1969.
$C_{20}H_{14}O_2Se$ Di-2-hydroxydi-1-naphthyl selenide (MORGAN and BURSTALL), 3269.
$C_{20}H_{14}O_6S_4$ 1:1'-Dithiodinaphthalene-8:8'-disulphinic acid (PRICE and SMILES), 2373.
$C_{20}H_{14}O_5N_4$ Dinitrobenzilphenylhydrazones (CHATTAWAY and COULSON), 1087, 1363.
$C_{20}H_{14}O_6S_2$ Bis-2'-carboxyphenylthiol-2:4-dihydroxybenzene (PRICE and SMILES), 2862.
$C_{20}H_{14}O_6S_4$ 1:1'-Dithiodinaphthalene-8:8'-disulphonic acid, and its sodium salt (PRICE and SMILES), 2372.
$C_{20}H_{15}ON$ 1-Hydroxy-1:3-diphenyl*iso*indole, and its hydrobromide (BOYD and LADHAMS), 2091.
$C_{20}H_{15}O_3N_3$ 4-Nitrobenzilphenylhydrazones (CHATTAWAY and COULSON), 1083.
$C_{20}H_{16}ON_2$ Nitroso-1:3-diphenyldihydro*iso*indole (BOYD and LADHAMS), 2093.
$C_{20}H_{16}O_3N_2$ Benzophenyl-3-nitrobenzylamide (REILLY, MOORE, and DRUMM), 564.
$C_{20}H_{17}OCl$ 3-Phenyl-5-chlorostyryl*cyclo*hexen-1-ones (HEILBRON and HILL), 2869.
$C_{20}H_{17}O_2N_3$ 4:4'-Diketo-1:1':2'-trimethyl-1':4'-dihydro-2(3')-quinolylquinazoline (HEILBRON, HOLT, and KITCHEN), 933.

$C_{20}H_{18}O_2S_2$ 1:3-Dibenzylthiolbenzene disulphoxides (BELL and BENNETT), 3192.

$C_{20}H_{18}O_3N_2$ Nitro-9-benzoyl-3-methyltetrahydrocarbazole (PLANT and ROSSER), 2459.

$C_{20}H_{18}O_4N_2$ 3-*o*-Carboxyphenylmethylcarbamyl-1:2-dimethyl-4-quinolone (HEILBRON, HOLT, and KITCHEN), 937.

$C_{20}H_{18}O_6Mo$ Molybdyl bisbenzoylacetone (MORGAN and CASTELL), 3255.

$C_{20}H_{18}O_{10}N_4$ 3:3′-Dinitrobenzidine (LE FÈVRE and TURNER), 252.

$C_{20}H_{19}ON$ 9-Benzoyl-3-methyltetrahydrocarbazole (PLANT and ROSSER), 2459.

$C_{20}H_{19}O_2N$ Diacetyltetrahydro-$\alpha'\beta'$-naphthacarbazole (OAKESHOTT and PLANT), 1845.

$C_{20}H_{19}O_3N$ Thebenine, constitution of (GULLAND and VIRDEN), 921.

$C_{20}H_{19}O_4N$ 3:4-Dimethoxy-6-ethylbenzylidenehippuric acid azlactone (BARGER and SILBERSCHMIDT), 2925.

$C_{20}H_{19}O_4N_5$ Ethyl 2-methylquinoxaline-3-pyruvate *p*-nitrophenylhydrazone (BENNETT and WILLIS), 1973.

$C_{20}H_{19}O_7N_3$ 5:5′-Dinitro-2′-piperidino-2-acetoxybenzophenone (LE FÈVRE), 3251.

$C_{20}H_{20}OSn$ Phenyl-*p*-tolylbenzylstannic hydroxide, and its salts (KIPPING), 2370.

$C_{20}H_{20}O_4N_2$ 11-Nitro-10-hydroxy-9-benzoyl-3-methylhexahydrocarbazole (PLANT and ROSSER), 2459.

$C_{20}H_{20}O_7N_2$ Substance, from *o*-nitrobenzyl chloride and ethyl acetoacetate (KERMACK and SLATER), 36.

$C_{20}H_{21}ON$ Benzoylhexahydroheptindole (PERKIN and PLANT), 2587.

9-Benzoyl-3-methylhexahydrocarbazole (PLANT and ROSSER), 2461.

$C_{20}H_{21}O_2N$ β-Naphthylimide of α-methyl*cyclo*pentane-1:1-diacetic acid (BARDHAN), 2597.

$C_{20}H_{21}O_4N$ Bulbocapnine methyl ether (GULLAND and HAWORTH), 1136.

$C_{20}H_{21}O_7N$ *trans*-α(6′-Methoxy-3′-ethylphenyl)-2-nitro-3:4-dimethoxycinnamic acid, and its ammonium salt (GULLAND and VIRDEN), 931.

$C_{20}H_{22}ON_2$ Acetyl-α-*NN*′-dimethyl-2-phenylnaphthylene-1:3-diamine (GIBSON, KENTISH, and SIMONSEN), 2136.

$C_{20}H_{22}O_2N_2$ Diethylaminoethyl-2′-cyanodiphenyl-2-carboxylate, and its hydrochloride (BELL), 3249.

Ethyl 3-ketophenheptamethylene-2-carboxylate phenylhydrazone (TITLEY), 2578.

$C_{20}H_{22}O_5N_2$ 2′-Nitro-6:3′:4′-trimethoxy-1-benzylidene-2-methyltetrahydro*iso*quinoline (GULLAND and HAWORTH), 2085.

$C_{20}H_{23}O_6N_2$ 2′-Nitro-6:7:3′:4′-tetramethoxy-1-benzyl-3:4-dihydro*iso*quinoline, and its salts (GULLAND and HAWORTH), 1836.

$C_{20}H_{23}O_3N$ Morphothebaine dimethyl ethers, and their salts (GULLAND and HAWORTH), 2087.

β-Naphthylamic acid of α-methyl*cyclo*pentane-1:1-diacetic acid (BARDHAN), 2597.

dl-3:4:6-Tetramethoxyaporphine, and its hydriodide (GULLAND and HAWORTH), 2086.

$C_{20}H_{23}O_5N$ *trans*-α(6′-Methoxy-3′-ethylphenyl)-2-amino-3:4-dimethoxycinnamic acid (GULLAND and VIRDEN), 932.

$C_{20}H_{24}O_3S$ Boruyl naphthalenesulphonates, decomposition and hydrolysis of (PATTERSON and MCALPINE), 2464.

$C_{20}H_{24}O_4N_2$ 2′-Amino-3′:4′-dimethoxy-6:7-methylenedioxy-1-benzyl-2-methyltetrahydro*iso*quinoline, and its dihydrochloride (GULLAND and HAWORTH), 1135.

$C_{20}H_{24}O_7N_2$ 2′ Nitro-3′:4′-dimethoxyphenylaceto-6-3:4-dimethoxyphenylethylamide (GULLAND and HAWORTH), 1834.

$C_{20}H_{25}O_9N$ Tetra-acetylglucoseanilide (BAKER), 1589.

$C_{20}H_{26}O_3N_2$ 2′-Amino-6:3′:4′-trimethoxy-1-benzyl-2-methyltetrahydro*iso*quinoline, and its dihydrochloride (GULLAND and HAWORTH), 2086.

20 IV

$C_{20}H_{12}O_4Cl_2S_2$ 1:1′-Dinaphthyl-2:2′-disulphonic acid (BARBER and SMILES), 1148.

$C_{20}H_{17}O_6N_3S$ 3:5-Dinitro-4-*p*-toluenesulphonmethylamidodiphenyl (BELL), 2776.

$C_{20}H_{18}O_4N_2S$ 5-Nitro-2-*p*-toluenesulphonmethylamidodiphenyl (BELL), 2775.

$C_{20}H_{18}O_6N_2S$ Ethyl *N*-benzenesulphonyl-8-nitro-1-naphthylaminoacetate (MILLS and ELLIOTT), 1299.

$C_{20}H_{18}O_6N_4As_2$ 8:8′-Diacetamido-3:3′-dihydroxy-6:6′-arseno-1:4-benz*iso*oxazine (NEWBERY, PHILLIPS, and STICKINGS), 3060.

$C_{20}H_{19}O_2NS$ 2-*p*-Toluenesulphonmethylamidodiphenyl (BELL), 2774.

$C_{20}H_{19}N_2IS$ Methylethylthio-ψ-cyanine iodides (HAMER), 214.

$C_{20}H_{19}N_2IS_2$ 2:2′:8-Trimethylthiocarbocyanine iodide (HAMER), 3162.

$C_{20}H_{20}ON_4S$ 3-Phenylmethylmethyleneamino-2:4-diketo-5-methyltetrahydrothiazole 2-phenylmethylmethylenehydrazone (STEPHEN and WILSON), 1418.

$C_{20}H_{21}O_6N_2I$ 2′-Nitro-3′:4′-dimethoxy-6:7-methylenedioxy-1-benzyl-3:4-dihydro-*iso*quinoline methiodide (GULLAND and HAWORTH), 1135.

$C_{20}H_{24}O_2NI$ 5:6-Dimethoxyaporphine methiodide (GULLAND and HAWORTH), 590.

$C_{20}H_{24}O_9NCl$ Tetra-acetylglucose-*p*-chloroanilide (BAKER), 1590.

$C_{20}H_{24}O_9NBr$ Tetra-acetylglucose *p*-bromoanilide (BAKER), 1590.

$C_{20}H_{26}O_6N_4As_2$ 3:3′-Di(β-hydroxyethylamino)-5:5′-diacetamido-4:4′-dihydroxyarsenobenzene (NEWBERY, PHILLIPS, and STICKINGS), 3064.

20 V

$C_{20}H_{13}O_2NClBr$ Chlorobromobenzamidophenyl benzoates (HUNTER and BARNES), 2060.

$C_{20}H_{13}O_2NClI$ 2-Chloro-6-iodo-4-benzamidophenyl benzoate (HUNTER and BARNES), 2066.

$C_{20}H_{13}O_2NBrI$ Bromoiodobenzamidophenyl benzoates (HUNTER and BARNES), 2062.

C_{21} Group.

$C_{21}H_{12}O_2$ Dinaphthaxanthone (CLEMO and SPENCE), 2819.

$C_{21}H_{12}O_3$ 9-*o*-Carboxyphenyl-9-hydroxyanthrone lactone (COOK), 63.

$C_{21}H_{12}O_6$ 2-Benzoylanthrapurpurin (PERKIN and STOREY), 237.

$C_{21}H_{14}O_2$ 9-*o*-Carboxyphenylanthracene (COOK), 64.

Semipinacolin, from benzylideneanthrone dibromide and silver oxide (COOK), 58

$C_{21}H_{14}O_3$ 9-*o*-Carboxyphenylanthrone (COOK), 64.

$C_{21}H_{14}O_4$ Lactonic acid of triphenylcarbinol-2:2′-dicarboxylic acid (COOK), 64.

$C_{21}H_{14}O_4$ 2-Benzoylbenzophenone-2′-carboxylic acid (COOK), 62.

$C_{21}H_{15}Cl$ 2-Chloro-9-benzylanthracene (BARNETT and WILTSHIRE), 1824.

Chloro-9-benzylanthracenes (COOK), 2806.

$C_{21}H_{16}O_2$ Substance, from reduction of semipinacolin, $C_{21}H_{14}O_2$ (COOK), 61.

$C_{21}H_{18}O_9$ Diethylcarbonatoanthragallol methyl ethers (PERKIN and STOREY), 242.

2:7-Diethylcarbonatoanthrapurpurin 1-methyl ether (PERKIN and STOREY), 236.

$C_{21}H_{22}O_8$ Ethyl 3:4:5-trimethoxybenzoylbenzoyloxyacetate (BRADLEY and ROBINSON), 1549.

$C_{21}H_{32}O$ 4-*iso*Propylstyryl nonyl ketone (HEILBRON and IRVING), 2325.

$C_{21}H_{44}O_3$ Batyl alcohol (HEILBRON and OWENS), 944.

21 III

$C_{21}H_{12}O_5S$ 2-Quinizarinphenylsulphone-2′-carboxylic acid (PRICE and SMILES), 3157.

$C_{21}H_{14}OCl_2$ 1:5-Dichloro-9-benzylanthrone (BARNETT and COOK), 571.

$C_{21}H_{14}O_6S$ 2-Toluene-*p*-sulphonylalizarin (PERKIN and STOREY), 241.

$C_{21}H_{14}ClBr$ 2-Chloro-10-bromo-9-benzylanthracene (BARNETT and WILTSHIRE), 1824.

Chlorobromo-9-benzylanthracenes (COOK), 2806.

1-Chloro-10-bromo-9-benzylidene-9:10-dihydroanthracene (COOK), 2806.

$C_{21}H_{14}ClBr_3$ 2-Chloro-10-bromo-9-benzylanthracene dibromide (BARNETT and WILTSHIRE), 1825.

$C_{21}H_{15}OCl$ 4-Chloro-ω-hydroxy-9-benzylanthracene (COOK), 2809.

1-Chloro-10-hydroxy-9-benzylidene-9:10-dihydroanthracene (COOK), 2807.

$C_{21}H_{15}N_2Cl$ 2-*p*-Chlorobenzyl-3-phenylquinoxaline (BENNETT and WILLIS), 1967.

$C_{21}H_{16}OCl_2$ 1:5-Dichloro-9-benzyl-9:10-dihydroanthranol (BARNETT and COOK) 572.

$C_{21}H_{17}OCl$ 1-Chloro-9-hydroxy-9-benzyl-9:10-dihydroanthracene (COOK), 2806.

$C_{21}H_{18}O_2N_2$ Homophthalanilide (DAVIES and POOLE), 1619.

$C_{21}H_{18}I_3Sb$ Tri-*m*-iodo-*p*-tolylstibine (GODDARD and YARSLEY), 723.

$C_{21}H_{19}O_2I$ 1:1′-Dimethyl*iso*cyanine iodide (HAMER), 213.

$C_{21}H_{20}O_4N_2$ 3-*o*-Carbomethoxyphenylmethylcarbamyl-1:2-dimethyl-4-quinolone (HEILBRON, HOLT, and KITCHEN), 937.

$C_{21}H_{21}O_{10}Cl$ 3-β-Glucosidylpelargonidin chloride (ROBERTSON and ROBINSON), 1469.

$C_{21}H_{21}ClSn$ Tri-*m*-tolylstannic chloride (KIPPING), 2369.

$C_{21}H_{22}ON_2$ Acetyl-*NN*′-trimethyl-2-phenylnaphthylene-1:3-diamine (GIBSON, KENTISH, and SIMONSEN), 2141.

$C_{21}H_{22}O_2N_2$ Strychnine, constitution of (FAWCETT, PERKIN, and ROBINSON), 3082.

$C_{21}H_{23}ON$ Benzoyloctahydroheptaquinoline (PERKIN and PLANT), 2588.

$C_{21}H_{23}O_6N$ α-3:4-Dimethoxy-6-ethylphenyl-β-6-nitro-3:4-dimethoxyphenylacrylic acid (BARGER and SILBERSCHMIDT), 2926.

$C_{21}H_{24}O_3N_2$ Acetyl derivative of 2-{4′:5′-dimethoxy-2′-β-methylaminoethyl) phenylindole (GULLAND and HAWORTH), 587.

$C_{21}H_{24}N_3Sb$ Tri-*m*-aminotri-*p*-tolylstibine (GODDARD and YARSLEY), 722.

$C_{21}H_{25}O_4N$ *dl*-Corytuberine dimethyl ether (GULLAND and HAWORTH), 1836.

$C_{21}H_{26}O_3N_2$ 2′-Acetylamino-6:7-dimethoxy-1-benzyl-2-methyltetrahydro*iso*-quinoline (GULLAND and HAWORTH), 589.

$C_{21}H_{27}O_9N$ Tetra-acetylglucose-*N*-methylanilide (BAKER), 1590.

Tetra-acetylglucose-*p*-toluidide (BAKER), 1589.

$C_{21}H_{27}O_{10}N$ Tetra-acetylglucose-*p*-anisidide (BAKER), 1590.

$C_{21}H_{28}O_4N_2$ 2′-Amino-6:7:3′:4′-tetramethoxy-1-benzyl-2-methyltetrahydro*iso*-quinoline, and its dihydrochloride (GULLAND and HAWORTH), 1836.

$C_{21}H_{28}O_4N_4$ Trimethylfructose phenylosazone (HAWORTH and LEARNER), 623.

21 IV

$C_{21}H_{16}O_8N_2S$ Nitrobenzyl esters of carboxyphenyl-*p*-nitrobenzylsulphones (PRICE and SMILES), 2861.

$C_{21}H_{18}O_2Br_4Se$ Tribromotrihydroxytrimethyltriphenylselenonium bromides (MORGAN and BURSTALL), 3267.

$C_{21}H_{12}O_7N_3Sb$ Tri-*m*-nitrotri-*p*-tolylstibine oxide (GODDARD and YARSLEY), 722.

$C_{21}H_{12}O_{12}N_3Sb$ Tri-*m*-nitrotri-*p*-tolylstibine dinitrate (GODDARD and YARSLEY), 722.

$C_{21}H_{22}O_3N_2Cl_2$ 4-Chloro-3-*o*-carbomethoxyphenylmethylcarbamyl-2-methyl-quinoline methochloride (HEILBRON, HOLT, and KITCHEN), 939.

$C_{21}H_{21}O_3ClSe$ Trihydroxytrimethyltriphenylselenonium chlorides (MORGAN and BURSTALL), 3266.

$C_{21}H_{21}O_6NSe$ Tri-4-hydroxytri-3-methyltriphenylselenonium nitrate (MORGAN and BURSTALL), 3267.

$C_{21}H_{21}N_2IS$ 1′:2-Diethylthio-ψ-cyanine iodide (HAMER), 213.

$C_{21}H_{21}N_2ISe_2$ 2:2′-Diethylselenocarbocyanine iodide (CLARK), 2318.

$C_{21}H_{22}ON_4S$ 3-Phenylmethylmethyleneamino-2:4-diketo-5-ethyltetrahydrothiazole 2-phenylmethylmethylenehydrazone (STEPHEN and WILSON), 1418.

$C_{21}H_{24}O_4NI$ Bulbocapnine methyl ether methiodide (GULLAND and HAWORTH), 1137.

$C_{21}H_{23}O_6N_2I$ 2′-Nitro-6:7:3′:4′-tetramethoxy-1-benzyl-3:4-dihydro*iso*quinoline methiodide (GULLAND and HAWORTH), 1836.

21 V

$C_{21}H_{20}O_3N_2ClI$ 4-Chloro-3-*o*-carbomethoxyphenylmethylcarbamyl-2-methylquinoline methiodide (HEILBRON, HOLT, and KITCHEN), 939.

$C_{21}H_{21}O_3Cl_3SeHg$ Tri-4-methoxytriphenylselenonium mercurichloride (MORGAN and BURSTALL), 3265.

C_{22} Group.

$C_{22}H_{14}O_5$ 1-Benzoylalizarin 2-methyl ether (PERKIN and STOREY), 240.

$C_{22}H_{16}O$ 2-Benzylidene-3-phenyl-Δ^3-benzopyran (DICKINSON, HEILBRON, and O'BRIEN), 2080.

$C_{22}H_{16}O_4$ Methyl 2-benzoylbenzophenone-2′-carboxylate (COOK), 62.

$C_{22}H_{16}O_5$ ω:4-Dibenzoyloxyacetophenone (ROBERTSON and ROBINSON), 1466.

$C_{22}H_{16}N_2$ 2-Styryl-3-phenylquinoxaline (BENNETT and WILLIS), 1972.

$C_{22}H_{16}Cl_2$ 1:5-Dichloro-9-benzyl-10-methylene-9:10-dihydroanthracene (BARNETT and COOK), 570.

$C_{22}H_{18}O_2$ 2-Hydroxy-α-phenylstyryl benzyl ketone (DICKINSON, HEILBRON, and O'BRIEN), 2080.

$C_{22}H_{18}O_5$ Resorcinolphenolphthalein 2′:4′-dimethyl ether (LUND), 1575.

$C_{22}H_{18}O_9$ *O*-Triacetylbrazilone (PERKIN, RÂY, and ROBINSON), 1513.

$C_{22}H_{22}O_8$ Ethyl dibenzoyltartrate (FINDLAY and CAMPBELL), 1774.

$C_{22}H_{22}O_9$ Acetylirigenin 7:3′-dimethyl ether (BAKER), 1031.

$C_{22}H_{24}O_7$ Ethyl *O*-benzoylsyringoylacetoacetate (BRADLEY and ROBINSON), 1556.

$C_{22}H_{24}Sn$ Triphenyl-*n*-butylstannane (KIPPING), 2370.

$C_{22}H_{32}O_2$ Menthyl methoxynaphthoates (BRETSCHER, RULE, and SPENCE), 1500.

$C_{22}H_{44}O_2$ Behenolic acid, synthesis of (BHATTACHARYA, SALETORE, and SIMONSEN), 2678.

22 III

$C_{22}H_{14}O_8N_4$ 2-(2:4-Dinitrostyryl)-3-phenylquinoxaline (BENNETT and WILLIS), 1972.

$C_{22}H_{15}O_2N_3$ 2-*p*-Nitrostyryl-3-phenylquinoxaline (BENNETT and WILLIS), 1972.

2-(β-Phenyl-*p*-nitrostyryl)quinoxaline (BENNETT and WILLIS), 1972.

$C_{22}H_{15}O_6Cl$ Benzoylpelargonidin chloride (ROBERTSON, ROBINSON, and SUGIURA), 1534.

$C_{22}H_{15}O_7Cl$ Benzoylcyanidin chloride (ROBERTSON and ROBINSON), 1528.

$C_{22}H_{16}O_{12}N_6$ Ethyl αβ-bis-2:4-dinitrophenyl-αβ-dicyanosuccinate (FAIRBOURNE and FAWSON), 1079.

$C_{22}H_{17}OCl$ Chloro-ω-methoxy-9-benzylanthracenes (COOK), 2808.

1-Chloro-10-methoxy-9-benzylidene-9:10-dihydroanthracene (COOK), 2808.

$C_{22}H_{17}O_2N_5$ Diketosuccinanil phenylosazone (CHATTAWAY and HUMPHREY), 1097.

$C_{22}H_{17}O_4N$ *r*- and *l*-Desylphthalamic acids (MCKENZIE and WALKER), 649.

$C_{22}H_{18}O_2N_6$ Diketosuccinophenylhydrazide phenylosazone (CHATTAWAY and HUMPHREY), 1097.

$C_{22}H_{18}O_4N_4$ 1-Hydroxy-3-(3′-nitrophenyl)-1:3-dihydrophthalazine-4-acetanilide (Rowe, Himmat, and Levin), 2559.

$C_{22}H_{19}O_3N_5$ Diketosuccinanilic acid phenylosazone (Chattaway and Humphrey), 1097.

$C_{22}H_{20}O_8S_2$ Ditoluene-*p*-sulphonylgallacetophenone (Perkin and Storey), 243.

$C_{22}H_{21}N_2I$ Methylethyl-ψ-cyanine iodide (Hamer), 210.

Trimethyl-ψ-cyanine iodide (Hamer), 211.

$C_{22}H_{22}O_2N_2$ Diacetyl-β-*NN′*-dimethyl-2-phenylnaphthylene-1:3-diamine (Gibson, Kentish, and Simonsen), 2140.

$C_{22}H_{23}O_4N_2$ 3-*o*-Carbethoxyphenylmethylcarbamyl-1:2-dimethyl-4-quinolone (Heilbron, Holt, and Kitchen), 937.

$C_{22}H_{22}N_2I_2$ 3:4′-Diquinolyl diethiodide (Mills and Ordish), 85.

$C_{22}H_{23}O_5N$ Oxydehydrocorydaline (Koepfli and Perkin), 2999.

$C_{22}H_{23}N_2I$ 1:3:3:1′-Tetramethylindo-ψ-cyanine iodide (Hamer), 214.

$C_{22}H_{24}O_5N_2$ 1-αγ-Ditolyl*iso*propylpyridinium nitrates (Boyd and Ladhams), 220.

$C_{22}H_{27}ON$ *l*-Benzoyloximino-α-curcumene (Rao and Simonsen), 2502.

$C_{22}H_{27}O_2N$ Dicarvacrylacetonitrile (Bell and Henry), 2224.

Dithymylacetonitrile (Bell and Henry), 2224.

Thymylcarvacrylacetonitrile (Bell and Henry), 2224.

$C_{22}H_{27}O_4N$ Dimethyl-laurotetaninemethine, and its hydriodide (Barger and Silberschmidt), 2921.

$C_{22}H_{29}O_2N$ Dithymylacetamide (Bell and Henry), 2224.

$C_{22}H_{30}ON_2$ *d*- and *l*-β-2:3:7-Trimethyl-1:2:3:4-tetrahydroquinoxalino-1-methylene-camphor (Gibson, Nutland, and Simonsen), 114.

$C_{22}H_{31}O_{16}N_3$ Substance, from hydrolysis of substance $C_{33}H_{40}O_{16}N$ (Henry and Sharp), 1115.

$C_{22}H_{32}ON_2$ *l*-α-Curcumenenitrolbenzylamine (Rao and Simonsen), 2501.

22 IV

$C_{22}H_{12}O_2N_5Cl_4$ Diketosuccinanil 2:4-dichlorophenylosazone (Chattaway and Humphrey), 1098.

$C_{22}H_{12}O_2N_5Br_4$ Diketosuccinanil 2:4-dibromophenylosazone (Chattaway and Humphrey), 1098.

$C_{22}H_{14}O_2N_6Cl_4$ Diketosuccinophenylhydrazide 2:4-dichlorophenylhydrazone (Chattaway and Humphrey), 1098.

$C_{22}H_{14}O_2N_6Br_4$ Diketosuccinophenylhydrazide 2:4-dibromophenylosazone (Chattaway and Humphrey), 1098.

$C_{22}H_{15}O_6N_3S_2$ 1-Dibenzenesulphonamido-8-nitronaphthalene (Mills and Elliott), 1299.

$C_{22}H_{20}O_4N_2Br_2$ 6-Bromo-3-*p*-bromo-*o*-carbethoxyphenylmethylcarbamyl-1:2-dimethyl-4-quinolone (Heilbron, Holt, and Kitchen), 941.

$C_{22}H_{22}O_2N_2Cl_2$ 4-Chloro-3-*o*-carbethoxyphenylmethylcarbamyl-2-methylquinoline methochloride (Heilbron, Holt, and Kitchen), 938.

$C_{22}H_{22}O_7N_2Cl_2$ 4-Chloro-3-*o*-carbethoxyphenylmethylcarbamyl-2-methylquinoline methoperchlorate (Heilbron, Holt, and Kitchen), 938.

$C_{22}H_{23}N_2IS_2$ 3-Methyl-2:2′-diethylthiocarbocyanine iodide (Hamer), 3162.

$C_{22}H_{24}O_2NCl$ 1-αγ-Di-*p*-tolyl*iso*propylpyridinium chlorate (Boyd and Ladhams), 220.

$C_{22}H_{28}O_2N_2Br_2$ Diphenacyldimethylpiperazinium dibromide (Stevens, Creighton, Gordon, and MacNicol), 3196.

$C_{22}H_{28}O_4NI$ *dl*-Corytuberine dimethyl ether methiodide (Gulland and Haworth), 1837.

22 V

$C_{22}H_{22}O_3N_2Cl_2BF_2$ 4-Chloro-6-bromo-3-*p*-bromo-*o*-carbethoxyphenylmethylcarbamyl-2-methylquinoline methochloride (HEILBRON, HOLT, and KITCHEN), 941.

$C_{22}H_{22}O_3N_2ClI$ 4-Chloro-3-*o*-carbethoxyphenylmethylcarbamyl-2-methylquinoline methiodide (HEILBRON, HOLT, and KITCHEN), 938.

C_{23} Group.

$C_{23}H_{14}O_6$ 2-Benzoyl-1-acetylalizarin (PERKIN and STOREY), 239.

$C_{23}H_{16}O_5$ *o*-Benzoylphenylacetoxyphthalide (COOK), 62.

$C_{23}H_{16}O_6$ Benzoylanthrapurpurin dimethyl ethers (PERKIN and STOREY), 237.

$C_{23}H_{18}O_3$ *o*-Hydroxybenzylidenephenylacetylacetophenone (LOVETT and ROBERTS), 1977.

$C_{23}H_{20}O_2$ 2-Methoxy-*α*-phenylstyryl benzyl ketone (DICKINSON, HEILBRON, and O'BRIEN), 2080.

$C_{23}H_{20}O_6$ Phloroglucinolphenolphthalein 2′:4′:6-trimethyl ether (LUND), 1575.

$C_{23}H_{26}Sn$ Diphenylbenzyl-*n*-butylstannane (KIPPING), 2371.

$C_{23}H_{28}O_2$ Menthyl diphenyl-2-carboxylate (BRETSCHER, RULE, and SPENCE), 1502.

$C_{23}H_{28}O_{12}$ *ω*-*O*-Tetra-acetyl-*β*-glucosidoxy-4-methoxyacetophenone (ROBERTSON and ROBINSON), 1467.

23 III

$C_{23}H_{16}O_7N_4$ Trinitrobenzoyltetrahydro-*αβ*-naphthacarbazole (OAKESHOTT and PLANT), 1843.

$C_{23}H_{17}O_2Cl$ Chloro-*ω*-acetoxy-9-benzylanthracenes (COOK), 2808.

1-Chloro-10-acetoxy-9-benzylidene-9:10-dihydroanthracene (COOK), 2807.

$C_{23}H_{17}O_5Cl$ 7-Hydroxy-5-benzoyloxy-4′-methoxyflavylium chloride (ROBERTSON, ROBINSON, and STRUTHERS), 1458.

$C_{23}H_{17}O_7Cl$ 5-*O*-Benzoylpeonidin chloride (MURAKAMI and ROBINSON), 1538.

$C_{23}H_{18}O_2N_2$ 3-Phenyl-2-phenylacetoxymethylquinoxaline (BENNETT and WILLIS), 1974.

$C_{23}H_{18}O_3N_2$ Nitrobenzoyltetrahydro-*α′β′*-naphthacarbazole (OAKESHOTT and PLANT), 1846.

$C_{23}H_{19}ON$ Benzoyltetrahydronaphthacarbazoles (OAKESHOTT and PLANT), 1843.

$C_{23}H_{19}OCl$ 4-Chloro-*ω*-ethoxy-9-benzylanthracene (COOK), 2810.

$C_{23}H_{19}O_2N_5$ Diketosuccinobenzylimide phenylosazone (CHATTAWAY and HUMPHREY), 1096.

$C_{23}H_{20}O_2N_6$ Diketosuccinophenylhydrazide *o*-tolylphenylosazone (CHATTAWAY and HUMPHREY), 1098.

Diketosuccinophenylmethylhydrazide phenylosazone (CHATTAWAY and HUMPHREY), 1098.

$C_{23}H_{20}O_3Cl_2$ Ethyl 3-chlorophenyl-5-chlorostyryl*cyclo*hexen-1-one-2-carboxylates (HEILBRON and HILL), 2869.

$C_{23}H_{21}ON$ Benzoylhexahydro-*αβ*-naphthacarbazoles (OAKESHOTT and PLANT), 1844.

$C_{23}H_{21}O_2N_3$ 2-Hydroxy-*α*-phenylstyryl benzyl ketone semicarbazone (DICKINSON, HEILBRON, and O'BRIEN), 2080.

$C_{23}H_{21}O_3N$ Dibenzoylnor-*d*-*ψ*-ephedrine (SMITH), 53.

$C_{23}H_{21}O_3Cl$ Ethyl 3-phenyl-5-chlorostyryl*cyclo*hexen-1-one-2-carboxylates (HEILBRON and HILL), 2868.

$C_{23}H_{22}O_2N_2$ *αγ*-Dibenzoylamino-*β*-phenylpropane (JACKSON and KENNER), 1659.

$C_{23}H_{22}O_3S_2$ Ditoluene-*p*-sulphonylgallacetophenone methyl ether (PERKIN and STOREY), 243.

$C_{23}H_{23}O_2N_3$ Benzoin-*δ*-(*α*-phenylethyl)semicarbazone (HOPPER and WILSON), 2485.

$C_{23}H_{33}O_4Cl$ Ethyl (γ-keto-α-phenyl-ε-2-chlorophenyl-Δδ-pentenyl)acetoacetate (Heilbron and Hill), 2868.

$C_{23}H_{23}N_2I$ 1:1′-Diethyl*iso*cyanine iodide (Hamer), 213.

1:1′-Diethyl-ψ-cyanine iodide (Hamer), 212.

1:6:1′:6′-Tetramethyl-ψ-cyanine iodide (Hamer), 211.

$C_{23}H_{25}O_4N$ Acetyltolylacetylthymylacetonitrile (Bell and Henry), 2225.

Benzoyloximino-derivatives of hydroxy-2:2:3:3-tetramethyl*cyclo*pentanones (Shoppee), 1668.

$C_{23}H_{26}O_4N_2$ Brucine, constitution of (Fawcett, Perkin, and Robinson), 3082.

$C_{23}H_{27}O_6N$ 6:7:3′:4′-Tetramethoxy-9-methyl-2′-carbomethoxy-3:4-dihydroprotopapaverine (Koepfli and Perkin), 2999.

23 IV

$C_{23}H_{17}O_2N_2Cl$ 3-Phenyl-2-*p*-chlorophenylacetoxymethylquinoxaline (Bennett and Willis), 1974.

$C_{23}H_{16}O_4N_2S$ 1:2-Naphthaquinone 2′-carboxyphenyl sulphoxide phenylhydrazone (Price and Smiles), 3159.

$C_{23}H_{26}O_4N_2S_2$ *pp*′-Ditoluenesulphonyl-αγ-amino-β-phenylpropane (Jackson and Kenner), 1659.

C_{24} Group.

$C_{24}H_{16}O_5$ Diacetoxy*iso*dinaphthylene oxide (Clemo and Spence), 2817.

$C_{24}H_{16}O_6$ Diacetoxydinaphthaquinone (Clemo and Spence), 2817.

$C_{24}H_{18}N_2$ 2:3-Distyrylquinoxaline (Bennett and Willis), 1968.

$C_{24}H_{20}O_2$ 4-Phenacyl-3-phenyl-2-methyl-1:4-benzopyran (Hill), 258.

$C_{24}H_{22}Cl_2$ 1:5-Dichloro-9-benzyl-10-*iso*propylanthracene (Barnett and Cook), 570.

$C_{24}H_{22}O_6$ ω-Benzoyloxy-4-benzyloxy-3:5-dimethoxyacetophenone (Bradley and Robinson), 1557.

Resorcinolphthalein tetramethyl ether (Lund), 1574.

$C_{24}H_{22}O_{11}$ Triacetylirigenin (Baker), 1028.

$C_{24}H_{24}O_{12}$ Iridin, constitution of (Baker), 1022.

$C_{24}H_{28}O_{12}$ ω-*O*-Tetra-acetyl-β-glucosidoxy-4-acetoxyacetophenone (Robertson and Robinson), 1466.

$C_{24}H_{30}O_3$ Menthyl 2′-methoxydiphenyl-2-carboxylate (Bretscher, Rule, and Spence), 1502.

24 III

$C_{24}H_{14}O_8N_6$ 2:3-Di(2:4-dinitrostyryl)quinoxaline (Bennett and Willis), 1970.

$C_{24}H_{16}O_4N_4$ 2:3-Di(nitrostyryl)quinoxalines (Bennett and Willis), 1969.

$C_{24}H_{16}N_2Cl_2$ 2:3-Di(chlorostyryl)quinoxalines (Bennett and Willis), 1971.

$C_{24}H_{16}N_2I_2$ 2:3-Di(*o*-iodostyryl)quinoxaline (Bennett and Willis), 1971.

$C_{24}H_{16}N_2Br_4$ 2:3-Distyrylquinoxaline tetrabromide (Bennett and Willis), 1968.

$C_{24}H_{19}O_3Cl$ 5-Benzoylmalvidin chloride (Bradley and Robinson), 1561.

$C_{24}H_{21}O_3Al$ Aluminium methyl salicylate (Burrows and Wark), 228.

$C_{24}H_{25}N_2I$ Methyldiethyl-ψ-cyanine iodide (Hamer), 212.

$C_{24}H_{27}N_2I$ 3:3-Dimethyl-1:1′-diethylindo-ψ-cyanine iodide (Hamer), 214.

$C_{24}H_{30}O_4N_4$ 4:4′-Dipiperidino-5:5′-dinitro-3:3′-dimethyldiphenyl (Le Fèvre and Turner), 967.

24 IV

$C_{24}H_{16}N_2Cl_2As_2$ 2:2′-Bis(10-chloro-5:10-dihydrophenarsazine) (Gibson and Johnson), 2208.

$C_{24}H_{16}N_2Br_2As_2$ 2:2′-Bis(10-bromo-5:10-dihydrophenarsazine) (GIBSON and JOHNSON), 2210.
$C_{24}H_{18}O_4N_2As_2$ 2:2′-Bis(phenarsazinic acid), and its salts (GIBSON and JOHNSON), 2209.
$C_{24}H_{22}O_6N_2As_2$ 4:4-Bis(diphenylamine-2′-arsinic acid) (GIBSON and JOHNSON), 2208.
$C_{24}H_{23}N_2BrS_2$ 3-Methyl-2:2′-diallylthiocarbocyanine bromide (HAMER), 3162.

C_{25} Group.

$C_{25}H_{16}N_2$ 2:3-Distyryl-6-methylquinoxaline (BENNETT and WILLIS), 1971.
$C_{25}H_{16}O_3$ 2-Benzoyl-1:7-diacetylanthrapurpurin (PERKIN and STOREY), 236.
$C_{25}H_{18}N_2$ Dibenzylidenequinoxalino*cyclo*pentane (BENNETT and WILLIS), 1973.
$C_{25}H_{20}O_5$ 5-Hydroxy-7:4′-dimethoxy-2-styryl*iso*flavone (BAKER and ROBINSON), 3116.
$C_{25}H_{22}Sn$ Triphenylbenzylstannane (KIPPING), 2368.
Triphenyl-*o*-tolylstannane (KIPPING), 2369.
$C_{25}H_{24}O_5$ Dipiperonylidene-3:3:4:4-tetramethyl*cyclo*pentanone (INGOLD and SHOPPEE), 391.
$C_{25}H_{46}O$ Cholesterol, dry distillation of (HEILBRON and SEATON), 347.

25 III

$C_{25}H_{16}O_4N_4$ Di-*p*-nitrobenzylidenequinoxalino*cyclo*pentane (BENNETT and WILLIS), 1973.
$C_{25}H_{16}O_8N_6$ 2:3-Di(2:4-dinitrostyryl)-6-methylquinoxaline (BENNETT and WILLIS), 1972.
$C_{25}H_{18}O_2N_4$ 2:3-Di(*m*-nitrostyryl)-6-methylquinoxaline (BENNETT and WILLIS), 1972.
$C_{25}H_{19}ON$ Diphenyl-2-carboxylylamide (BELL), 3247.
$C_{25}H_{20}O_2N$ 4-Benzylaminomethyl-1-phenyl-3:4-dihydro*iso*quinoline (JACKSON and KENNER), 1660.
$C_{25}H_{21}O_7Cl$ 7-Hydroxy-5-benzoyloxy-3:3′:5′-trimethoxyflavylium chloride (ROBERTSON, ROBINSON, and SUGIURA), 1536.
$C_{25}H_{21}O_8Cl$ 5:7:4′-Trihydroxy-3:3′:5′-trimethoxyflavylium chloride (BRADLEY and ROBINSON), 1567.
$C_{25}H_{21}N_2I$ Dimethylbenz-ψ-cyanine iodide (HAMER), 212.
$C_{25}H_{22}O_4N_2$ Deoxytrimethylbrazilone (PERKIN, RAY, and ROBINSON), 1508.
$C_{25}H_{22}O_6N_4$ *d*-α-1:4-Di-*m*-nitrobenzoyl-2:3:7-trimethyl-1:2:3:4-tetrahydroquinoxaline (GIBSON, NUTLAND, and SIMONSEN), 113.
$C_{25}H_{24}O_2N_2$ 1-Dibenzyl-2-pyrrolidone-5-carboxyanilide (GRAY), 1266.
$C_{25}H_{25}O_3N$ Benzylidenethebainone (GULLAND), 704.
$C_{25}H_{27}O_3N$ Benzylidenethebainol (GULLAND), 706.
Benzylthebainones (GULLAND), 705.
$C_{25}H_{27}O_5N$ Benzylidenehydroxydihydrothebainone (GULLAND), 704.
$C_{25}H_{28}O_3N_2$ Benzylthebainone oxime (GULLAND), 706.
$C_{25}H_{29}O_7N$ Pyropseudaconine (SHARP), 3098.
$C_{25}H_{41}O_8N$ Pseudaconine (HENRY and SHARP), 1112.

25 IV

$C_{25}H_{23}ON_6S$ 3-Phenylmethylmethyleneamino-2:4-diketo-5-phenyltetrahydrothiazole 2-phenylmethylmethylenehydrazone (STEPHEN and WILSON), 1418.
$C_{25}H_{24}O_2N_2S$ *p*-Toluenesulphonyl-α-*NN*′-dimethyl-2-phenylnaphthylene-1:3-diamine (GIBSON, KENTISH, and SIMONSEN), 2137.

$C_{25}H_{30}O_4N_2S_2$ *NN'*-Dimethyl-*NN'*-di-*p*-toluenesulphonyl-$\alpha\gamma$-diamino-β-phenylpropane (JACKSON and KENNER), 1659.

C_{26} Group.

$C_{26}H_{18}O$ 2-Benzylidene-3-phenyl-Δ^3-β-naphthapyran (DICKINSON, HEILBRON, and O'BRIEN), 2081.

$C_{26}H_{20}O_3$ 4-Hydroxytetraphenylmethane-3-carboxylic acid (BOYD and HARDY), 634.

$C_{26}H_{22}O_5$ 5:7:4'-Trimethoxy-2-styryl*iso*flavone (BAKER and ROBINSON), 3116.

$C_{26}H_{24}O_2$ Substance, from deoxytrimethylbrazilone and perbenzoic acid (PERKIN, RÂY, and ROBINSON), 1509.

$C_{26}H_{26}O_6$ Phloroglucinolphthalein hexamethyl ether (LUND), 1573.

$C_{26}H_{28}O_3$ Hexamethoxytriphenylmethane-4-carboxylic acid (LUND), 1572.

26 III

$C_{26}H_{18}OS_2$ Benzildiphenylene-2:2'-mercaptol (BARBER and SMILES), 1147.

$C_{26}H_{18}O_4N_2$ 2:3-Di(methylenedioxystyryl)quinoxaline (BENNETT and WILLIS) 1968.

$C_{26}H_{19}O_3Br$ 5-Bromo-4-hydroxytetraphenylmethane-3-carboxylic acid (BOYD and HARDY), 635.

$C_{26}H_{20}O_4N_6$ Dinitrobenzilosazone (CHATTAWAY and COULSON), 1087, 1363.

$C_{26}H_{30}O_6N_2$ 4:4''-Diethyloxamidodiphenyl (LE FÈVRE and TURNER), 251.

$C_{26}H_{21}O_2N_5$ 4-Nitrobenzilosazone (CHATTAWAY and COULSON), 1083.

$C_{26}H_{22}O_2N_2$ 2:3-Di(methoxystyryl)quinoxalines (BENNETT and WILLIS), 1969.

$C_{26}H_{24}O_4N_2$ Dianhydro-6-aminopiperonaldihydrocodeinone (GULLAND), 703.

$C_{26}H_{25}O_5N$ Piperonylidenethebainone (GULLAND), 705.

$C_{26}H_{30}O_3N_4$ Benzylthebainone semicarbazones (GULLAND), 705.

$C_{26}H_{31}O_4N$ Diacetylcarvacrylacetonitrile (BELL and HENRY), 2224.

Diacetylthymylacetonitrile (BELL and HENRY), 2224.

Diacetylthymylcarvacrylacetonitrile (BELL and HENRY), 2225.

26 IV

$C_{26}H_{18}O_2N_2Br_2$ 5:4'-Dibromo-3:4-dibenzoylaminodiphenyl (HINKEL and HEY), 1840.

$C_{26}H_{19}NClBr$ 4-Chloro-9-benzylanthracene-ω-pyridinium bromide (COOK), 2809.

$C_{26}H_{20}ON_4Br_2$ Azoxybenzylidene-*p*-bromoanilines (NISBET), 3123.

$C_{26}H_{20}O_2N_2S_2$ 2:2'-Dibenzamidodiphenyl disulphide (CLARK), 2320.

$C_{26}H_{22}N_2Cl_2As_2$ 2:2'-Bis(10-chloro-8-methyl-5:10-dihydrophenarsazine) (GIBSON and JOHNSON), 2210.

$C_{26}H_{22}N_2Br_2As_2$ 2:2'-Bis(10-bromo-8-methyl-5:10-dihydrophenarsazine) (GIBSON and JOHNSON), 2211.

$C_{26}H_{22}N_2I_2As_2$ 2:2'-Bis(10-iodo-8-methyl-5:10-dihydrophenarsazine) (GIBSON and JOHNSON), 2211.

$C_{26}H_{24}O_4N_2As_2$ 2:2'-Bis(8-methylphenarsazinic acid), and its sodium salt (GIBSON and JOHNSON), 2210.

$C_{26}H_{28}O_3NI$ Benzylidenethebainone methiodide (GULLAND), 705.

C_{27} Group.

$C_{27}H_{20}$ 9:9-Diphenyl-10-methylene-9:10-dihydroanthracene (BARNETT and COOK), 570.

$C_{27}H_{46}$ ψ-Cholestene, formation of, from dry distillation of cholesterol (HEILBRON and SEXTON), 347.

27 II

$C_{27}H_{22}O_6$ 5-Acetoxy-7:4′-dimethoxy-2-styryl*iso*flavone (BAKER and ROBINSON), 3116.

$C_{27}H_{22}O_{14}$ Hexa-acetylirigenol (BAKER), 1030.

$C_{27}H_{24}O$ 4-Methoxy-3-methyltetraphenylmethane (BOYD and HARDY), 637.

$C_{27}H_{24}O_5$ 5:7:4′-Trimethoxy-2-styryl-6-methyl*iso*flavone (BAKER and ROBINSON), 3117.

$C_{27}H_{28}Sn$ Phenyldi-*p*-tolylbenzylstannane (KIPPING), 2370.
Phenyltribenzylstannane (KIPPING), 2367.

$C_{27}H_{32}O_3$ *m*-Hydroxyphenyldithymylmethane (BELL and HENRY), 2226.

$C_{27}H_{42}O_2$ Campnospermonol (JONES and SMITH), 65.

$C_{27}H_{44}O$ Cholestenone, preparation of (SEXTON), 2825.

27 III

$C_{27}H_{17}Cl_2Br$ ω-Bromo-1:5-dichloro-9-benzyl-10-phenylanthracene (COOK), 2805.

$C_{27}H_{18}OCl_2$ ω-Hydroxy-1:5-dichloro-9-benzyl-10-phenylanthracene (COOK), 2805.

$C_{27}H_{20}OCl_2$ 1:5-Dichloro-10-phenyl-9-benzyl-9:10-dihydroanthranol (BARNETT and COOK), 569.

$C_{27}H_{20}O_4N_2$ 2:3-Di(methylenedioxystyryl)-6-methylquinoxaline (BENNETT and WILLIS), 1971.

$C_{27}H_{21}ON$ Benzoyl-1:3-diphenyldihydro*iso*indole (BOYD and LADHAMS), 2093.

$C_{27}H_{23}OBr$ 3-Bromo-4-methoxy-5-methyltetraphenylmethane (BOYD and HARDY), 638.

$C_{27}H_{24}O_2N_2$ 2:3-Di(*p*-methoxystyryl)-6-methylquinoxaline (BENNETT and WILLIS), 1971.

$C_{27}H_{25}N_2I$ Diethylbenz-ψ-cyanine iodide (HAMER), 212.

$C_{27}H_{27}O_9Al$ Aluminium ethyl salicylate (BURROWS and WARE), 228.

$C_{27}H_{30}O_6N_2$ αγ-Dibenzoylamino-β-3:4-dibenzoyloxyphenylpropane (JACKSON and KENNER), 1662.

$C_{27}H_{31}O_2Cl$ Chlorophenyldithymylmethanes (BELL and HENRY), 2226.

$C_{27}H_{31}O_4N$ Nitrophenyldithymylmethanes (BELL and HENRY), 2226.

27 IV

$C_{27}H_{27}O_4N_2I$ Dianhydro-6-aminopiperonaldihydrocodeinone methiodide (GULLAND), 703.

C_{28} Group.

$C_{28}H_{20}Cl_2$ 1:5-Dichloro-9-benzyl-10-benzylidene-9:10-dihydroanthracene (BARNETT and COOK), 570.

$C_{28}H_{22}O_4$ 4-Acetoxytetraphenylmethane-3-carboxylic acid (BOYD and HARDY), 635.

$C_{28}H_{24}O_2$ 4-Acetoxy-3-methyltetraphenylmethane (BOYD and HARDY), 637.

$C_{28}H_{28}Si$ Tetrabenzylsilicane, preparation of (STEELE and KIPPING), 1431.

$C_{28}H_{28}Sn$ Tritolyltolylstannanes (KIPPING), 2369.

$C_{28}H_{34}O_8$ Ethyl βγ-diphenylbutane-αaδδ-tetracarboxylates (VOGEL), 1019.

$C_{28}H_{48}O$ Substance, from reduction of campnospermonyl methyl ether (JONES and SMITH), 69.

$C_{28}H_{46}O_2$ Substance, from reduction of campnospermonol (JONES and SMITH), 69.

$C_{28}H_{48}O_2$ Hydrocampnospermonyl methyl ether (JONES and SMITH), 69.

$C_{28}H_{50}O$ Substance, from reduction of campnospermonyl methyl ether (JONES and SMITH), 69.

28 III

$C_{28}H_{21}OCl$ 1-Chloro-10:10-dibenzylanthrone (BARNETT and COOK), 572.

$C_{28}H_{22}OCl_2$ 1:5-Dichloro-9:10-dibenzyl-9:10-dihydroanthranol (BARNETT and COOK), 569.
$C_{28}H_{24}ON_2$ *m*-Azoxybenzylidene-*p*-toluidine (NISBET), 3124.
$C_{28}H_{24}O_3S_2$ Benzil benzyl mercaptol dioxide (CHIVERS and SMILES), 699.
$C_{28}H_{26}O_4N_2$ 2:3-Di(3:4-dimethoxystyryl)quinoxaline (BENNETT and WILLIS), 1969.
$C_{28}H_{27}O_3N_3$ 4-Anilino-3-*o*-carbethoxyphenylmethylcarbamyl-1-methyl-2-methylene-1:2-dihydroquinoline (HEILBRON, HOLT, and KITCHEN), 939.
$C_{28}H_{32}O_8Br$ Ethyl *r*-$a\delta$-dibromo-$\beta\gamma$-diphenylbutane $aa\delta\delta$-tetracarboxylate (VOGEL), 1020.
$C_{28}H_{49}O_2N$ Hydrocampnospermonyl methyl ether oxime (JONES and SMITH), 69.

C_{29} Group.

$C_{29}H_{20}O_2$ 3:3′-Diphenyldibenzo*spiro*pyran (DICKINSON, HEILBRON, and O'BRIEN), 2081.
$C_{29}H_{26}O$ 9:9-Dibenzyl-10-methyl-9:10-dihydroanthranol (BARNETT and COOK), 571.
$C_{29}H_{30}O_{12}$ ω-*O*-Tetra-acetyl-β-glucosidoxy-4-benzoyloxyacetophenone (ROBERTSON and ROBINSON), 1466.
$C_{29}H_{46}O_2$ Campnospermonyl methyl ether (JONES and SMITH), 67.

29 III

$C_{29}H_{22}OCl_2$ ω-Ethoxy-1:5-dichloro-9-benzyl-10-phenylanthracene (COOK), 2805.
$C_{29}H_{22}O_3N_2$ Dibenzoyl derivative of substance $C_{15}H_{14}ON_2$ (KRISHNAMURTI), 416.
$C_{29}H_{28}O_4N_2$ 2:3-Di(3:4-dimethoxystyryl)-6-methylquinoxaline (BENNETT and WILLIS), 1971.
$C_{29}H_{32}ON_2$ *NN′*-Dimethyl-2-phenylnaphthylene-1:3-diamino-*d*-methylenecamphors (GIBSON, KENTISH, and SIMONSEN), 2137.
$C_{29}H_{47}O_2N$ Campnospermonyl methyl ether oxime (JONES and SMITH), 67.

C_{30} Group.

$C_{30}H_{26}O$ Bis-$a\gamma$-diphenylallyl ether (SHOPPEE), 2570.
Bis-$a\gamma$-diphenylpropenyl ether (SHOPPEE), 2570.

30 III

$C_{30}H_{22}O_4Mo$ Molybdyl bisdibenzoylmethane (MORGAN and CASTELL), 3255.
$C_{30}H_{24}OBr_2$ Bis-β-bromo-$a\gamma$-diphenylpropenyl ether (SHOPPEE), 2570.
$C_{30}H_{24}O_2N_2$ *NN′*-Dicinnamoylbenzidine (LE FÈVRE and TURNER), 252.
$C_{30}H_{24}O_3N_2$ Dibenzoyl derivative of substance $C_{16}H_{16}ON_2$ (KRISHNAMURTI), 416.
$C_{30}H_{26}OBr_2$ Bis-$\beta\gamma$-dibromo-$a\gamma$-diphenylpropyl ether (SHOPPEE), 2570.
$C_{30}H_{26}O_4N_2$ $a\gamma$-Dibenzoylamino-β-*p*-benzoyloxyphenylpropane (JACKSON and KENNER), 1661.
$C_{30}H_{27}O_3N_5$ Diketosuccinodibenzylamic acid phenylosazone (CHATTAWAY and HUMPHREY), 1097.
$C_{30}H_{31}O_3P$ Bis-$a\gamma$-diphenoxy*iso*propyl phosphate (BOYD and LADHAMS), 220.

30 IV

$C_{30}H_{28}O_4N_2S_2$ Di-*p*-toluenesulphonyl-2-phenylnaphthylene-1:3-diamines (GIBSON, KENTISH, and SIMONSEN), 2138.
$C_{30}H_{28}O_6N_2S_3$ Diphenylamine-2:4:6-trisulphonanilide (DAVIES and WOOD), 1125.

C_{31} Group.

$C_{31}H_{46}O_2$ Trithymylmethane (BELL and HENRY), 2223.

31 III

$C_{31}H_{45}O_{10}N$ Triacetylpyropseudaconine (SHARP), 3099.

C_{32} Group.

$C_{32}H_{24}O_{10}$ 7:3′-Dibenzoylirigenin (BAKER), 1028.

32 III

$C_{32}H_{24}O_6N_2$ *NN′*-Di-*o*-carbethoxybenzoylbenzidine (LE FÈVRE and TURNER), 251.

$C_{32}H_{28}O_2N_4$ 4-Anilino-3-*o*-anilinophenylmethylcarbamyl-1-methyl-2-methylene-1:2-dihydroquinoline (HEILBRON, HOLT, and KITCHEN), 940.

$C_{32}H_{32}O_2N_6$ Benzildi-*d*-δ-(α-phenylethyl)semicarbazone (HOPPER and WILSON), 2488.

$C_{32}H_{49}O_{11}N$ Triacetylmethylpseudaconine (SHARP), 3102.

32 IV

$C_{32}H_{30}O_4N_2S_2$ Di-*p*-toluenesulphonyl-*NN′*-dimethyl-2-phenylnaphthylene-1:3-diamine (GIBSON, KENTISH, and SIMONSEN), 2139.

C_{33} Group.

$C_{33}H_{24}$ 9:9-Diphenyl-10-benzylidene-9:10-dihydroanthracene (BARNETT and COOK), 571.

33 II

$C_{33}H_{26}O$ 9:9-Diphenyl-10-benzyl-9:10-dihydroanthranol (BARNETT and COOK), 571.

33 III

$C_{33}H_{29}O_3P$ Di-*p*-tolyl triphenylmethylphosphite (BOYD and HARDY), 636.

$C_{33}H_{40}O_{16}N_4$ Substance, from oxidation of pseudaconitine (HENRY and SHARP), 1113.

$C_{33}H_{43}O_4N_3$ 4-Hydroxy-3-aldehydo-5-methyl-2-*iso*propylphenyldicarvacrylmethane (BELL and HENRY), 2221.

$C_{33}H_{49}O_{12}N$ Tetra-acetylpseudaconine (HENRY and SHARP), 1112.

$C_{33}H_{51}O_{11}N$ Triacetylethylpseudaconine (SHARP), 3102.

C_{34} Group.

$C_{34}H_{28}O$ 10-Phenyl-9:9-dibenzyl-9:10-dihydroanthranol (BARNETT and COOK), 571.

34 III

$C_{34}H_{37}OCl$ 1-Chloro-9-phenyl-10:10-dibenzyl-9:10-dihydroanthranol-9 (BARNETT and COOK), 572.

$C_{34}H_{31}N_3Br_2$ Neocyanine methobromide (HAMER), 1477.

$C_{34}H_{37}O_7N$ Demethylpyropseudaconine (SHARP), 3099.

$C_{34}H_{39}O_8P$ Bis-αγ-di-*p*-tolyloxy*iso*propyl phosphate (BOYD and LADHAMS), 219.

$C_{34}H_{43}O_{17}N_3$ Substance, from oxidation of pseudaconitine (HENRY and SHARP), 1117.

$C_{34}H_{45}O_{11}N$ Substance, and its salts, from oxidation of pseudaconitine (HENRY and SHARP), 1117.

$C_{34}H_{47}O_{10}N$ Pyropseudaconitine (SHARP), 3097.

C_{35} Group.

$C_{35}H_{50}O_6N_2$ Batyl *p*-nitrobenzoate (HEILBRON and OWENS), 944.

$C_{35}H_{51}O_{11}N$ Veratroylmethylpseudaconine, and its salts (SHARP), 3100.

$C_{35}H_{54}O_5N_2$ Batyl phenylurethane (HEILBRON and OWENS), 944.

C_{36} Group.

$C_{36}H_{30}O$ 9:9:10-Tribenzyl-9:10-dihydroanthranol (BARNETT and COOK), 571.

36 III

$C_{36}H_{26}O_5N_2$ 2-Azoxystyryl-3-methylchromones (NISBET), 3123.

$C_{36}H_{30}O_7Se_2$ Tri-4-hydroxytriphenylselenonium oxide (MORGAN and BURSTALL), 3265.

$C_{36}H_{50}O_2Cl_2$ Bis-(4-chlorostyryl nonyl ketone) (HEILBRON and IRVING), 2326.

$C_{36}H_{51}O_{12}N$ Pseudaconitine (SHARP), 3094; and its salts (HENRY and SHARP), 1111.

$C_{36}H_{53}O_2N$ Bis(styryl nonyl ketone) oxime (HEILBRON and IRVING), 2324.

36 IV

$C_{36}H_{32}O_{17}S_3Se_3$ Triphenoxselenylium dibisulphate sulphuric acid dihydrate (DREW), 523.

36 V

$C_{36}H_{30}O_6Cl_6Se_2Pb$ Tri-4-hydroxytriphenylselenonium chloroplatinate (MORGAN and BURSTALL), 3265.

C_{37} Group.

$C_{37}H_{24}O_2$ 3:3′-Diphenyldi-β-naphtha*spiro*pyran (DICKINSON, HEILBRON, and O'BRIEN), 2082.

$C_{37}H_{24}O_8$ *O*-Tribenzoylbrazilone (PERKIN, RÂY, and ROBINSON), 1513.

$C_{37}H_{46}O_6$ Triacetylcarvacrylmethane (BELL and HENRY), 2223.
Triacetylthymylmethane (BELL and HENRY), 2223.

37 III

$C_{37}H_{37}N_3Br_2$ Neocyanine ethobromide (HAMER), 1477.

$C_{37}H_{37}N_3I_2$ Neocyanine ethiodide (HAMER), 1476.

$C_{37}H_{45}O_{17}N_3$ Acetyl derivative of substance $C_{28}H_{40}O_{16}N$ (HENRY and SHARP), 1114.

$C_{37}H_{53}O_{12}N$ Acetylveratroylmethylpseudaconine, and its perchlorate (SHARP), 3101.

37 IV

$C_{37}H_{32}O_6N_2S_2$ Tri-*p*-toluenesulphonyl-2-phenylnaphthylene-1:3-diamine (GIBSON, KENTISH, and SIMONSEN), 2139.

C_{38} Group.

$C_{38}H_{52}O_6$ Bis-(3:4-methylenedioxystyryl nonyl ketone) (HEILBRON and IRVING), 2325.

$C_{38}H_{56}O_2$ Bis-(4-methylstyryl nonyl ketone) (HEILBRON and IRVING), 2325.

$C_{38}H_{58}O_4$ Bis-(4-methoxystyryl nonyl ketone) (HEILBRON and IRVING), 2324.

38 III

$C_{38}H_{35}O_{11}Cl$ 3-*O*-Tetra-acetyl-β-glucosidoxy-7-hydroxy-5-benzoyloxy-4′-acetoxyflavylium chloride (ROBERTSON and ROBINSON), 1467.

$C_{38}H_{53}O_{13}N$ Acetylpseudaconitine, and its perchlorate (SHARP), 3105.

C_{39} Group.

$C_{39}H_{51}O_{13}N$ Triacetyldemethylpyropseudaconitine (SHARP), 3098.

$C_{39}H_{55}O_{13}N$ Diacetylveratroylmethylpseudaconine (SHARP), 3102.

C_{40} Group.

$C_{40}H_{40}O_{12}$ Ethyl di(*O*-benzyl syringoylsuccinate) (BRADLEY and ROBINSON), 1558.

$C_{40}H_{60}O_6$ Bis-(3:4-dimethoxystyryl nonyl ketone) (HEILBRON and IRVING), 2325.

40 III

$C_{40}H_{55}O_{14}N$ Diacetylpseudaconitine (SHARP), 3105.

C_{42} Group.

$C_{42}H_{64}O_2$ Bis-(4-*iso*propylstyryl nonyl ketone) (HEILBRON and IRVING), 2325.

42 III

$C_{42}H_{42}OSi_2$ Tetrabenzylsilicyl oxide, preparation of (STEELE and KIPPING), 1431.

$C_{42}H_{42}O_7Se_2$ Trihydroxytrimethyltriphenylselenonium oxides (MORGAN and BURSTALL), 3266.

C_{44} Group.

$C_{44}H_{42}O_6N_4ClI$ 4′-Chloro-3:3′-di(*o*-carbethoxyphenylmethylcarbamyl)-1:2:1′-trimethyl*iso*cyanine iodide (HEILBRON, HOLT, and KITCHEN), 940.

C_{45} Group.

$C_{45}H_{55}O_{12}N$ Benzoylpseudaconitine, and its perchlorate (SHARP), 3104.

C_{57} Group.

$C_{57}H_{104}O_5$ Triolein, heating of, with sulphur (KNIGHT and STAMBERGER), 2791.

PROCEEDINGS

OF THE

CHEMICAL SOCIETY.

Ordinary Scientific Meeting, Thursday, January 19th, 1928, at 8 p.m., Professor H. BRERETON BAKER, C.B.E., D.Sc., F.R.S., President, in the Chair.

The PRESIDENT referred to the loss sustained by the Society, through death, of the following Fellows:

	Elected.	Died.
William H. Darling	May 4th, 1871.	Nov. 18th, 1927.
Alfred M. Hanson	Feb. 21st, 1889.	Dec. 7th, 1926.
Lucy Higginbotham	Dec. 7th, 1922.	Nov. 22nd, 1927
Thomas E. Mackenzie	Feb. 15th, 1900.	Oct. 18th, 1927.
Alfred J. Squires	Feb. 18th, 1892.	Oct. 9th, 1927.

The PRESIDENT announced that:

1. The names of members of Council who retire at the Annual General Meeting on March 22nd, 1928, and who are ineligible for re-election to the same office until after the lapse of one year, are as follows:

President: Prof. H. B. BAKER.
Treasurer: Prof. J. F. THORPE.
Secretary: Dr. T. SLATER PRICE.
Vice-Presidents who have filled the office of President: Prof. H. E. ARMSTRONG, Dr. ALEXANDER SCOTT, Prof. W. P. WYNNE.
Vice-Presidents who have not filled the office of President: Prof. J. B. COHEN, Dr. N. V. SIDGWICK.

Ordinary Members of Council:

(*a*) Town Members: Prof. H. BASSETT, Mr. F. W. GAMBLE, Dr. J. KENYON, Mr. B. D. PORRITT, and Mr. G. STUBBS.
(*b*) Country Members: Dr. F. A. FREETH and Prof. F. J. WILSON.

The following vacant places in the Council fall due to be filled at the Annual General Meeting of the Society, which will be held at Burlington House on Thursday, March 22nd, 1928, at 4 p.m.:

President	One vacancy.
Treasurer	One vacancy.
Secretary	One vacancy.
Vice-Presidents who have filled the office of President	Three vacancies.

(*Note.—Sir William J. Pope was elected last April to fill the vacancy caused by the death of Dr. A. W. Crossley; his election will be confirmed at the next Annual General Meeting.*)

Vice-Presidents who have not filled the office of President	Two vacancies.
Ordinary Members of Council:	
(*a*) Town Members (*i.e.* those living within a radius of 50 miles from London)	Six vacancies.
(*b*) Country Members (*i.e.* those living beyond a radius of 50 miles from London)	Two vacancies.

(*Note.—This year the vacancies in category* (a) *are increased by one owing to the resignation of Dr. R. H. Pickard, who is no longer resident in the London area.*)

The Council has nominated Prof. J. F. THORPE to the office of President; Dr. T. SLATER PRICE to the office of Treasurer; and Prof. T. S. MOORE to the office of Secretary.

2. The following Address of Congratulation had been presented to the Institute of Chemistry on December 15th, 1927, the occasion of the Jubilee Celebrations of the foundation of the Institute:

The Chemical Society
to
The Institute of Chemistry of Great Britain and Ireland.

We, the President and Fellows of the Chemical Society, offer our most cordial congratulations to the President, Fellows, and Associates of the Institute of Chemistry on the auspicious occasion of the Jubilee Celebration of the Foundation of the Institute.

It is with the sincerest pleasure and gratitude that we place on record our deep sense of the eminent services which the Institute of Chemistry has so constantly rendered to the profession of Chemistry. Throughout the fifty years of its existence, the Institute, by means of its examinations, its high ideals of professional conduct, and its watchful guard over the interests of properly qualified chemists, has striven with remarkable success to raise the standard of professional knowledge and practice, and to secure for the profession of chemistry the status in our national life which it so eminently deserves.

The Chemical Society regards with the highest esteem and appreciation the achievements of the Institute. It recalls with a deep sense of gratitude the names not only of that eminent band of men who founded it, but of those who, by their devoted labour during the past fifty years, have contributed so materially to the furtherance of the profession of Chemistry. The Institute of Chemistry may continue to rely on the co-operation of the Chemical Society in the pursuance of the work it has taken in hand.

Signed on behalf of the Chemical Society,

H. B. BAKER,	*President.*
JOCELYN THORPE,	*Treasurer.*
T. SLATER PRICE, C. S. GIBSON,	*Secretaries.*
F. G. DONNAN,	*Foreign Secretary.*

Sealed in Council this fifteenth day of December, One Thousand Nine Hindred and Twenty-Seven.

The following were formally admitted Fellows of the Chemical Society: B. J. Corder, F. G. Kny-Jones, M. P. Oommen, M. J. Wilson-Smith, E. N. Eccott, F. L. Warren, and W. D. Scott.

Certificates were read for the first time in favour of:

Stanley Baker, M.Sc., Ph.D., Holmside, Bedlington, Northumberland.
Ramesh Chandra Banerji, M.Sc., Sainyer Gate, Jhansi, U.P., India.
Harold Hayden Barber, B.Sc., F.I.C., Arch Hill, Arnold, Notts.
Harold Graham Bott, B.Sc., 167, Stratford Road, Sparkbrook, Birmingham.
Reginald Bowsher, B.Sc., 9, Byron Road, Wembley.
Bibhuti Bhuson Chaudhuri, M.Sc., Chemical Inspector's Office, Indian Ordnance Department, Kirkee, India.
William Fraser Donald, 74, Railway Parade, Kogarah, Sydney.
Tom Farrar, 41, Bridget Street, Rugby.
George William Ferguson, 7A, North Road, Highgate, N. 7.
Frank Lathe Gilbert, B.Sc., 23, Guest Road, Cambridge.
Horace Arthur Hampton, B.Sc., 13, Arch Hill Street, Netherton, Dudley.
Clive Whelpton Holman, A.M.I.Mech.E., Clarendon Hotel, Montpelier Road, Blackheath, S.E. 3.
Marshall Holmes, M.Sc., Sudan Club, Khartoum.
James Hood, 21, Dock Street, Dundee.
Arthur Jackson, B.Sc., 66, Taylor Hill Road, Huddersfield.
Anantrao Ramchandra Kagal, B.A., B.Sc., 3/17, Bhagirathi Buildings, Chikalwadi, Grant Road, Bombay.
Herbert Davenport Kay, Ph.D., D.Sc., 7, Victoria Road, Chingford, E. 4.
Frank Eugene Lathe, B.A., M.Sc., National Research Council, Ottawa.
Kenneth Hugh Lauder, B.Sc., St. Andrew's College, The University, Sydney.
Abraham Learner, B.Sc., 509, Bristol Road, Selly Oak, Birmingham.
John Vaughan Loach, B.Sc., 6, Twyning Road, City Road, Birmingham.
John Longwell, M.Sc., A.I.C., 45, Warrington Crescent, Maida Vale, W. 9.
Charles George Lyons, B.A., Trinity Hall, Cambridge.

Birendra Keshary Mandal, Jharia Mines Board of Health, Dhanbad, India.
Hamilton Ryoichi Matsuda, c/o Tokushima Technical College, Shikoku, Japan.
Thomas Henry Morton, B.Sc., 2, Trinity Street, Langley, Birmingham.
Leslie Wallace Mullinger, 149, Fillebrook Road, Leytonstone, E. 11.
William George Painton, B.Sc., A.I.C., 17, Marlborough Road, Gunnersbury, W. 4.
Eric Pascal, M.A., 68, Hadham Road, Bishop's Stortford.
Walter A. Patrick, B.Sc., Ph.D., Johns Hopkins University, Baltimore, Md., U.S.A.
William Arthur Roach, B.Sc., A.R.C.S., A.I.C., Ford House, High Street, West Malling, Kent.
Hans Nicolai Kellermann Rördam, D.Sc., Polyteknisk Læreanstalt, Sölvgade 83, Copenhagen K.
Roland Scott, River View, Middleton-One-Row, Darlington.
Babu Lal Singh, The Shree Krishna Deshi Sugar Works, Jhusi, B.N.W.Ry., Allahabad.
Henry Geoffrey Smith, B.Sc., 39, Headingley Mount, Headingley, Leeds.
James Andrew Buchan Smith, B.Sc., 35, St. John's Road, Selly Park, Birmingham.
Flaxney Percival Stowell, B.Sc., Ph.D., 10, Grosvenor Mansions, Broad Walk, Buxton.
Harold Warris Thompson, Trinity College, Oxford.
Clarence Cyril Tipper, B.Sc., 6, Rochester Road, Southsea.
Robert Stuart Tipson, B.Sc., 111, Allesley Road, Coventry.
Ralph Cuthbert Traill, M.Sc., Clare College, Cambridge.
William Reed Veazey, A.B., Ph.D., Case School of Applied Science, Cleveland, Ohio, U.S.A.
Ahmed Kamel Wahbi, 329, Great Western Street, Rusholme, Manchester.
Angus FitzCharles Henderson Ward, B.A., B.Sc., 7, Manor Street, Cambridge.
John Ivor Webb, B.Sc., 12, Third Avenue, Selly Park, Birmingham.

The following Certificates have been authorised by the Council for presentation to ballot under Bye-Law I (2) in favour of :

George Ernest Barton-Hobbs, 236, Chelmsford Road, Durban, Natal.
Mario Betti, Dr.Chem., R. Universita, Bologna.
Constant Frederik van Duin, Ph.D., 34, Nieuwe Gracht, Utrecht.
Thomas Robert Hughes, 47, Colin Street, West Perth, Australia.
Giorgio Renato Levi, Dr.Chem., Viale Romagna, 37, Milan.
Fritz Lenze, Eisenzahnstrasse 5, Berlin.

The following papers were read :

"*cyclo*Telluropentane." By. G. T. Morgan and H. Burgess.

"Syntheses of cyclic compounds. Part II. Racemic and meso ethyl βγ-diphenylbutane-ααδδ-tetracarboxylate. Synthesis of a truxinic acid." By I. Vogel.

"Properties of conjugated compounds. Part IV. The formation of isomeric additive dibromides from butadiene." By E. H. Farmer, C. D. Lawrence, and J. F. Thorpe.

ORDINARY SCIENTIFIC MEETING, THURSDAY, FEBRUARY 2nd, 1928, AT 8 P.M.

At present the following papers have been received for reading:

"Some experiments on diffusion in solid metals." By J. W. JENKIN and C. H. DESCH.

"The alkaloids of some Indian aconites; *Aconitum rotundifolium*, *A. Balfourii*, and *A. deinorrhizum*." By T. A. HENRY and T. M. SHARP.

"The synthesis of *meso*-alkyl and *meso*-aryl anthracene derivatives. Part III." By E. DE BARRY BARNETT and J. W. COOK.

LECTURE.

Professor A. Fowler, F.R.S., will deliver his Lecture entitled "Spectra and Atoms" in the Rooms of the Society on Thursday, February 23rd, 1928, at 8 p.m.

ANNUAL GENERAL MEETING AND ANNIVERSARY DINNER.

The Annual General Meeting will be held in the Society's Rooms on Thursday, March 22nd, 1928, at 4 p.m., and the Anniversary Dinner will take place the same evening at the Hotel Victoria, Northumberland Avenue, W.C. 2.

List of Papers, or Abstracts thereof, received between December 1st, 1927, and January 19th, 1928. (This List does not include the titles of papers which have appeared in the Journal, or which have been read at a Scientific Meeting.)

"The nitration of benzaldoxime and some of its derivatives." By O. L. BRADY and B. E. M. MILLER.

"The rearrangement of benzyl phenyl ether." By W. F. SHORT.

"The addition of bromine to ethylenic compounds in non-hydroxylic solvents." By D. M. WILLIAMS and T. C. JAMES.

"The effect of catalysts on the speed of explosion, infra-red emission, and ionisation of gaseous explosions of carbon monoxide and oxygen." By W. E. GARNER and C. H. JOHNSON.

"Composition of bleaching powder." By C. T. KINGZETT.

"Syntheses in the phenazine series." By H. MCCOMBIE, H. A. SCARBOROUGH, and W. A. WATERS.

"The oxidation of diphenylamine in concentrated sulphuric acid solution." By S. H. TUCKER.

"Studies on hydrogen cyanide. Part I. Mercury methyl cyanide and the alleged isomerides of hydrogen cyanide." By J. E. COATES, L. E. HINKEL, and T. H. ANGEL.

"*α-iso*Propylglutaconic acid." By K. V. HARIHARAN, K. N. MENON, and J. L. SIMONSEN.

"The constituents of Indian turpentine from *Pinus longifolia*, Roxb. Part IV." By P. P. PILLAY and J. L. SIMONSEN.

"The parachor and chemical constitution. Part VII. Further examples of semipolar double bonds." By A. FREIMAN and S. SUGDEN.

"The nature of the alternating effect in carbon chains. Part XXIII. Anomalous orientation by halogens, and its bearing on the problem of the *ortho–para* ratio, in aromatic substitution." By C. K. INGOLD and C. C. N. VASS.

"The nature of the alternating effect in carbon chains. Part XXIV. The directive action in aromatic substitution of certain groups containing unsaturated linkings." By J. W. BAKER, K. E. COOPER, and C. K. INGOLD.

"The action of alcoholic potassium hydroxide upon *o*-, *m*-, and *p*-nitrophenetoles." By D. H. RICHARDSON and F. W. SMITH.

"The adsorption of hydrogen ions and its effect on the swelling and electrical charge of gelatin." By B. N. GHOSH.

"Nitrosation of phenols. Part V. 5-Chloro-3-hydroxyanisole. An example of an *o*-nitrosophenol." By H. H. HODGSON and J. S. WIGNALL.

"On the possibility of ring-chain valency tautomerism and of a type of mobile-hydrogen tautomerism analogous to the Wagner–Meerwein re-arrangement." By C. K. INGOLD and C. W. SHOPPEE.

"The parachor and chemical constitution. Part VIII. Ring-chain valency tautomerism in phorone derivatives." By S. SUGDEN.

"Some sulphur derivatives of aromatic methyl ethers." By H. H. HODGSON and F. W. HANDLEY.

"The ratio of the heats of combustion of benzoic acid and salicylic acid. (A reply to E. Berner.)" By P. E. VERKADE and J. COOPS.

"Synthetical experiments in the phenanthreno*iso*quinoline alkaloids. Part I. A synthesis of I⁻: 2-dimethoxyaporphine." By J. M. GULLAND and R. D. HAWORTH.

"Optically active derivatives of phenylaminoacetic acid." By A. MCKENZIE and N. WALKER.

"Investigations on the preparation of organic compounds of antimony: *p*-tolyl derivatives." By A. E. GODDARD and V. E. YARSLEY.

"Equilibrium between alcohols and salts. Part II." By E. LLOYD, C. B. BROWN, D. G. R. BONNELL, and W. J. JONES.

"Syntheses in the indole series. Part III. The theory of anhydronium base formation and the constitution of methosulphates with some observations on the fluorescence of 5 : 6-benz-4-carboline and its derivatives." By W. O. KERMACK and R. H. SLATER.

"Note on the nitration of benzylaniline." By J. REILLY and J. J. MOORE.

"The acetoacetic ester condensation." By M. C. FRANKLIN and W. F. SHORT.

"The Budde effect with a mixture of bromine vapour and air." By E. BROWN and D. L. CHAPMAN.

"The chlorination of anilides. Part II. The decomposition of *N*-chloroacetanilide by heat." By A. E. BRADFIELD.

"The solution tension of silver in solvents other than water." By F. K. V. KOCH.

"Caproic and caprylic allyl esters." By V. DEULOFEU.

"The synthesis of *meso*-alkyl and *meso*-aryl anthracene derivatives. Part III." By E. DE B. BARNETT and J. W. COOK.

"Reaction between nitrous acid and hydrogen sulphide." By L. S. BAGSTER.

"Autoxidation during slow combustion." By E. W. J. MARDLES.

"Studies in China wood oil. Part II. The oxidation of β-elæostearic glyceride." By R. S. MORRELL and S. MARKS.

"A chemical method for preparing carbon hydrosol." By E. CHIRNOAGA.

"The electro-deposition of indium with the dropping mercury cathode." By S. TAKAGI.

"Aromatic thionyl and chlorothionyl derivatives. Part IV. The mechanism of the condensation of thionyl-phenols with organic acids. The estimation of phenols in the presence of their acetates." By F. E. JONES and A. GREEN.

"Some experiments on diffusion in solid metals." By J. W. JENKIN and C. H. DESCH.

"The origin of the spectrum of the glow of phosphorus." By H. J. EMELÉUS and R. H. PURCELL.

"Derivatives of γ-xylose. A study of xylosemonoacetone and its conversion into 2 : 3 : 5-trimethyl γ-xylonolactone." By W. N. HAWORTH and C. R. PORTER.

"The absorption spectra of anthracene derivatives. Part I." By E. DE B. BARNETT, J. W. COOK, and T. E. ELLISON.

"Derivatives of 1 : 3-dithiolane and of 1 : 3-dithian." By J. C. A. CHIVERS and S. SMILES.

"The introduction of the triphenylmethyl group into phenols." By D. R. BOYD and D. V. N. HARDY.

"Colloidal platinum. Part III. The natural acidity and the acid coagulation of colloidal platinum." By S. W. PENNYCUICK and R. J. BEST.

"Studies in the sub-atomic structure of the elements. Part I." By L. H. SENSICLE.

"Acid and salt effects in catalysed reactions. Part XII. The water catenary of ($H-H_2O-OH$) in the iodination of acetone." By H. M. DAWSON and A. KEY.

CERTIFICATES OF CANDIDATES FOR ELECTION AT THE BALLOT TO BE HELD AT THE ORDINARY SCIENTIFIC MEETING ON THURSDAY, FEBRUARY 16TH, 1928.

BAKER, STANLEY, Holmside, Bedlington, Northumberland. British. Chemist. M.Sc. (Dunelm). Research student at Armstrong College from 1921 to 1924. Ph.D. (Dunelm) 1925. *J.C.S.*, 1925, **127**, 365. (*Signed by*) W. N. Haworth, W. Charlton, Stanley Peat, Harald Nielsen.

BARBER, HAROLD HAYDEN, Arch Hill, Arnold, Notts. British. Chemical Research and part-time lecturer, University College, Nottingham. B.Sc. Hons. Chemistry, London. Fellow of the Institute of Chemistry. "The Production of Fat by a Species of *Penicillium* grown in Sucrose Solution," *J. Soc. Chem. Ind.*, 1927, 200T. (*Signed by*) F. Stanley Kipping, F. C. Laxton, B. D. Shaw.

BOTT, HAROLD GRAHAM, 167, Stratford Road, Sparkbrook, Birmingham. British. Research Student, University of Birmingham. B.Sc. (Hons. 1st). (*Signed by*) W. N. Haworth, H. D. K. Drew, E. L. Hirst.

BOWSHER, REGINALD, 9, Byron Road, N. Wembley, Middlesex. British. Technologist to E. H. Spicer & Co., Ltd., 72, Wigmore St., W. 1. B.Sc., Pure Chemistry, 2nd Class Hons. (external) (Heidelberg, No. 2714). Consulting Chemist to above firm, also acting in same capacity in Great Britain for the Abbott Laboratories, Chicago, and Chemisch. Pharmaceutische A.-G. Bad., Hamburg. (*Signed by*) John Dall, Thomas Stephenson, William Robson.

BUTTERWORTH, BASIL, 6, Belgrave Road, Wanstead, E. 11. English. Research Student at the East London College. B.Sc. (London). (*Signed by*) W. H. Patterson, D. C. Jones, E. Roberts.

CATTERMOLE, JESSIE, 207, Norbury Crescent, London, S.W. 16. British. A Student in Chemistry. (*Signed by*) James F. Spencer, Mollie Barr, Ernest S. Hedges.

CHAUDHURI, BIBHUTI BHUSON, Chemical Inspector's Office, Indian Ordnance Department, Kirkee, India. Indian. Third Assistant to the Chemical Inspector, I.O.D. M.Sc., Class I, in Applied Chemistry (Calcutta University). Working as the third assistant to the Chemical Inspector, Indian Ordnance Department. (*Signed by*) J. N. Mukherjee, A. Marshall, M. L. Dey.

COHEN, JACOB DAVIS, 24, Alconbury Road, Clapton, London, E. 5. British. Research Student. B.Sc. (Lond.) 1926 (Hons.). A.C.G.F.C. (1926). Neil Arnott Scholarship and Medal, July 1926. Since Oct. 1926 I have been carrying out physical chemistry research at Imperial College—Royal College of Science. (*Signed by*) James C. Philip, H. J. T. Ellingham, J. L. E. Lewkowitsch, M. K. Maitra.

CROSSLEY, MOSES LEVEROCK, 734, Park Avenue, Plainfield, New Jersey. American. Chief Chemist, Calco Chemical Co., Bound Brook, N.J. Prior to 1918 Prof. of Chemistry, Wesleyan University. Author of several technical and non-technical papers, published in American Journals. President, American Institute of Chemists, 1924— . (*Signed by*) A. Clayton, Alan W. C. Menzies, L. W. McCay.

DONALD, WILLIAM FRASER, 74, Railway Parade, Kogarah, Sydney, Australia. Australian. Pharmacist. Certificate of Department of Pharmacy, University of Sydney, late Chief Assistant Chemist, Laboratory of Australian Drug Co., Ltd., Sydney; late Chief Assistant Chemist, Laboratory of Elliott Bros., Ltd., Sydney. Desires to receive the publications of the Society in order to keep in touch with the progress of chemistry. (*Signed by*) John Duncan, Thos. H. Moore, G. F. Merson.

FARRAR, TOM, 41, Bridget Street, Rugby. British. Chief Chemist and Supervisor of Manufacture (Cement). Twenty-five years' experience in the scientific side of cement manufacture, after laboratory training at the Craven Science School, Hull, and the Hull Technical Schools (known to-day as the Hull and Yorkshire Technical College), and then pupil under Dr. Prentice and James Watson, B.Sc., etc. (*Signed by*) Cecil B. O. Jones, Percy G. Lloyd, Jas. H. Edmondson.

FENTON, GEOFFREY WILLIAM, 7, St. John's Avenue, Newsome, Huddersfield, Yorks. British. Research Student of Organic Chemistry, Leeds University. B.Sc. (Hons.), Leeds 1927. Training in the methods of scientific research under the direction of Professor C. K. Ingold, F.R.S. (*Signed by*) C. K. Ingold, C. W. Shoppee, E. Rothstein.

FERGUSON, GEORGE WILLIAM, 7A, North Road, Highgate, N. 7. British. Assistant to Consulting Chemist. Student at Birkbeck College, University of London. (*Signed by*) Ernest J. Parry, C. T. Bennett, Samuel Sugden.

FLINT, CAPTAIN JAMES, M.C., 82, Sunny Gardens, Hendon, London, N.W. 4. British. Manager Scientific and Research Dept., Sandoz Chemical Works. Member of the Pharmaceutical Society. Associated with the manufacture of chlorophyll and alkaloids by special processes. (*Signed by*) F. S. Kipping, J. B. Firth, F. C. Laxton, B. D. Shaw, E. B. R. Prideaux.

GILBERT, FRANK LATHE, 23, Guest Road, Cambridge. British. Research Student. B.Sc. (special), London University. First Class Honours Chemistry. *J.C.S.*, 1927, 2164, 2295. (*Signed by*) T. M. Lowry, G. Jessop, Rose R. Goldstein.

GOODEVE, CHARLES FREDERICK, University College Hall, Ealing, W. 5. British. Research Student. B.Sc. (Manitoba) 1925. M.Sc. (Manitoba) 1927. Publications: "Alternating Current Electrolysis," *Eng. Journ. Can.*, 1927, **10**, 3; *Trans. Am. Electrochem. Soc.*, 1927, **51**, 273; *Trans. Roy. Soc. Can.*, 1927. Assistant Lecturer (Manitoba), 1925–27. 1851 Exhibition Scholar, 1927. (*Signed by*) F. G. Donnan, S. Barratt, B. Topley.

GOSSET, MARION, 17, Queen Anne's Grove, Bedford Park, Chiswick, W. 4. British. Junior Assistant, Science Library, Science Museum, S.W. 7. A.R.C.S. (Chemistry). Hons. B.Sc. (London, Chemistry). Student at the Royal College of Science, Imperial College of Science and Technology, 1921–25. (*Signed by*) H. B. Baker, M. A. Whiteley, James C. Philip, Jocelyn Thorpe.

GRANT, EDGAR BEATTIE, 7, Alexandra Place, Jesmond, Newcastle-on-Tyne. English. Chemist. Member of the Pharmaceutical Society of Great Britain. Have been studying for the major examination at the above Society's College in London, and obtained Ph.C. in April, 1927. (*Signed by*) J. B. Firth, D. Foggan, William Mair.

GROVES, LESLIE GEORGE, 22, Chadway, Chadwell Heath, Essex. British. Research Student. B.Sc. (Hons.) London. (*Signed by*) E. E. Turner, R. J. W. Le Fèvre, H. A. Mayes.

GULL, HERBERT CHARLES, 26, Twyford Road, Ilford, Essex. British. Research Student at East London College. B.Sc. (London, 1st Class Honours in Chemistry). (*Signed by*) E. E. Turner, R. J. W. Le Fèvre, A. Brewin.

HAGYARD, THOMAS, 3, Station Road, Eaglescliffe S.O. Co. Durham. English Technical Chemist. External London B.Sc., special, Chemistry, 1st Class Hons. About four years' Industrial Research at Messrs. Stockton-on-Tees Chemical Works, under the direction of D. Tyrer, D.Sc. Now studying for External London M.Sc. (*Signed by*) Allan E. Mitchell, W. J. V. Ward, R. G. Franklin.

HAMPTON, HORACE ARTHUR, 13, Arch Hill St., Netherton, nr. Dudley. British. Research Chemist at the Birmingham University. First Class Honours B.Sc. in the School of Chemistry at the Birmingham University. (*Signed by*) W. N. Haworth, E. L. Hirst, H. D. K. Drew.

HEY, DONALD HOLROYDE, 14, Grosvenor Road, Sketty, Swansea. British. Research Student. B.Sc. (Lond.). B.Sc. (Wales), 1st Class Hons. in Chemistry, University of Wales Post-graduate Studentship. "The Effect of Electrode Material on Oxidation Potentials," Butler, Hugh, and Hey; *Trans. Faraday Soc.*, 1926, **21**. (*Signed by*) J. E. Coates, L. E. Hinkel, E. E. Ayling, N. H. Hartshorne.

HOLMAN, CLIVE WHELPTON, Fraser and Chalmers Works, Erith, Kent. English. Mechanical Engineer. Graduate and, later, Associate by Examination, of the Institution of Mechanical Engineers. For some years employed by the South Metropolitan Gas Company. Now interested in mining and metallurgical plant, employed at Fraser and Chalmers Works. (*Signed by*) Bernard W. Holman, J. W. Hinchley, J. N. Sugden.

HOLMES, MARSHALL, Sudan Club, Khartoum, The Sudan. British. Lecturer in Chemistry and Physics, The Kitchener Medical School, Khartoum. M.Sc. (Belfast). Lecturer in Chemistry and Physics, The Kitchener School of Medicine, Khartoum. *J.C.S.*, 1926, 1690, 1898. (*Signed by*) A. J. Allmand, Samuel Smiles, E. W. McClelland.

HOLMES, THEODORA MARY, 24, Clifton Gardens, London, W. 9. British. Research Chemist. A.R.C.S. (Chemistry), Hons. B.Sc. London (Chemistry). Student at the Royal College of Science, Imperial College of Science and Technology, 1922–27. (*Signed by*) H. B. Baker, M. A. Whiteley, James C. Philip, Jocelyn Thorpe.

HOOD, JAMES, 21, Dock Street, Dundee, Forfarshire. British. Pharmacist. Member of the Pharmaceutical Society of Great Britain. Chief Pharmacist, Dundee Royal Infirmary. I am interested in practical and theoretical chemistry. (*Signed by*) William McHutchison, Andrew S. Matchet, William Mair.

HORTON, MIRIAM IVY, 59, Ingleby Road, Ilford, Essex. British. Student at East London College since Oct. 1924. (*Signed by*) E. E. Turner, E. Roberts, A. Brewin.

JACKSON, ARTHUR, 66, Taylor Hill Road, Taylor Hill, Huddersfield, Yorkshire. British. B.Sc. (1st Class) Chem. Leeds. Research Student, Organic Chemistry Dept., Leeds University. (*Signed by*) C. K. Ingold, Florence R. Shaw, H. Burton.

JAMES, ROBERT GILBERT, "Belle Vue," Harold Road, Deal, Kent. British. Research in Pure Chemistry, University of Birmingham (D.S.I.R. Research Grant for 1927–28). Ordinary Degree of B.Sc., 1st Division and

Distinction in Chemistry (1924), and Honours Degree, 1st Class (1925), Birmingham University. Elected A.I.C. (1927). Chidlaw Exhibition (1922) to Birmingham University (on Joint Board Higher School Certificate, in which I obtained a Distinction in Chemistry). "Co-ordination Compounds of Quinquevalent Molybdenum," *J.C.S.*, 1927, 2145. (*Signed by*) Wm. Wardlaw, H. M. Spittle, W. J. Hickenbottom, F. W. Pinkard.

KAGAL, ANANTRAO RAMCHANDRA, 3/17, Bhagirathi Buildings, Chikalwadi, Grant Road, Bombay, India. Indian. Factory Inspector (Bombay Government). B.A. B.Sc. (Hons. Chem.) (Bombay University). Four years with The Eastern Chemical Co., Ltd., Bombay, manufacturers of heavy chemicals. (*Signed by*) Harry Sharpe, A. R. Normand, Sadashiv Parashuram Nair.

KAY, HERBERT DAVENPORT, 7, Victoria Road, Chingford, E. 4. British. Beit Memorial Fellow for Medical Research. Ph.D. (Cambridge). D.Sc. (Manchester). Various papers on enzymes, phosphorus metabolism, etc., in *Biochemical Journal* and medical journals. (*Signed by*) Arthur Smithells, F. Gowland Hopkins, Arthur Harden, J. C. Drummond.

LATHE, FRANK EUGENE, National Research Council, Ottawa, Canada. Canadian. Metallurgical Chemist. B.A. (Chem.). B.Sc. and M.Sc. (Metallurgy), McGill University. (*Signed by*) Frank T. Shutt, R. B. Walker, F. G. Wait.

LAUDER, KENNETH HUGH, St. Andrew's College, The University, Sydney, N.S.W., Australia. British. Science Research Scholar, Sydney University. B.Sc. (Hons., Class I, Chemistry), Sydney. Science Research Scholar in Chemistry at Sydney University. Tutor in Chemistry at St. Andrew's College, Sydney University. Paper on Alumini-Oxalates, unpublished as yet, but ready for publication. (*Signed by*) Charles E. Fawsitt, G. J. Burrows, J. Kenner, J. C. Earl, Francis Lions.

LEARNER, ABRAHAM, 509, Bristol Rd., Selly Oak, Birmingham. English. Research Student. B.Sc., Durham, Honours Chemistry. Research under Prof. Haworth, D.Sc., at University of Birmingham since Sept. 1925. Haworth, Hirst, and Learner, *J.C.S.*, 1927, 1040, 2432. (*Signed by*) W. N. Haworth, H. D. K. Drew, S. Peat.

LEONARD, ALFRED WILLIAM, 72, Hatherley Gardens, East Ham, London, E. 6. British. Research Student, East London College. B.Sc. (Hons. Chem.), London University. (*Signed by*) E. E. Turner, H. A. Mayes, A. Brewin.

LOACH, JOHN VAUGHAN, 6, Twyning Road, City Road, Birmingham. British. Research Student, Chemistry Dept., Birmingham University. B.Sc., 1st Class Hons. in Chemistry. University Scholar. McCarthy Exhibitioner. (*Signed by*) W. N. Haworth, Wm. Wardlaw, C. E. Wood, H. D. K. Drew, H. M. Spittle, L. W. Needham, Stanley Peat, W. Charlton.

LONGWELL, JOHN, 45, Warrington Crescent, Maida Vale, London, W. 9. British. Temporary Assistant Chemist, Government Laboratory. B.Sc. (1st Hons.). M.Sc., Queen's University, Belfast. A.I.C. Research (post-graduate) at King's College, London. Science Master at the Academical Institution, Coleraine, North Ireland. Assistant Chemist at the Government Laboratory. *J.C.S.*, 1923, **123**, 3310. (*Signed by*) J. W. A. Woodley, E. H. Nurse, J. J. Fox.

LOVETT, ARTHUR BERTRAM EDMUND, 4, Prior Street, Greenwich, S.E. 10. British. Student. B.Sc. (Lond.), 1st Class Honours, 1927. (*Signed by*) E. E. Turner, D. C. Jones, E. Roberts.

LYONS, CHARLES GEORGE, Trinity Hall, Cambridge. English. Research Student. B.A., 1st Class Part II, Natural Sciences Tripos, Cambridge. Just

starting a course of research at the Physical Chemical Laboratory, Cambridge. (*Signed by*) T. M. Lowry, E. K. Rideal, R. G. W. Norrish.

MANDAL, BIRENDRA KESHARY, Public Analyst, Jharia Mines Board of Health, Dhanbad, Bihar and Orissa, India. Bengalee Hindu. Public Analyst. First Class diploma in Industrial Chemistry, B.E. College, Sibpur, 1914. Tech. Chemist, The Cawnpore Cotton Mills, Ltd., 1914–15. Analytical and Manf. Chemist, Smith Stanistreet Co., Ltd., Calcutta, 1915–22. Public Analyst, Jharia Mines Board of Health, Dhanbad, since 1922. (*Signed by*) Surendra Nath Dey, Charles Forrester, K. N. Bagchi.

MATSUDA, HAMILTON RYOICHI, c/o Tokushima Technical College, Shikoku, Japan. Japanese. Lecturer in Chemistry since April 1923. (*Signed by*) Masumi Chikashigé, Yasuhiko Asahina, Junzo Shinoda.

MORTON, THOMAS HENRY, 2, Trinity Street, Langley, Birmingham. British. Research Student. B.Sc. with Honours in Chemistry. (*Signed by*) W. N. Haworth, H. D. K. Drew, E. L. Hirst.

MULLINGER, LESLIE WALLACE, 149, Fillebrook Road, Leytonstone, E. 11. British. Student at East London College (University of London). Inter B.Sc., London. Desires to receive the publications, to attend the meetings, and use the Library. (*Signed by*) E. E. Turner, R. J. W. Le Fèvre, D. C. Jones.

PAINTON, WILLIAM GEORGE, 17, Marlborough Road, Gunnersbury, London, W. 4. English. Technical Chemist. B.Sc. (Lond.), Hons. Chem. A.I.C. Works Manager and Chemist. Engaged in manufacture of Foods (Infant and Invalid). (*Signed by*) Charles Dorée, F. H. Lowe, J. C. Crocker.

PASCAL, ERIC, 68, Hadham Road, Bishop's Stortford, Herts. British. Assistant Master, Bishop's Stortford College. M.A. Cantab. (Nat. Sci. Tripos). Teaching Chemistry in Bishop's Stortford College since 1921. (*Signed by*) F. S. Young, E. H. Tripp, J. A. Aeschlimann.

PATRICK, WALTER A., Johns Hopkins University, Baltimore, Md., U.S.A. U.S.A. Professor of Chemistry. Ph.D., Göttingen. B.Sc., Syracuse, N.Y., U.S.A. Colloidal Chem., "Adsorption of Vapours," *J. Amer. Chem. Soc.*, **42**, **44**; *J. Phys. Chem.*, **25**, **29**; "Adsorption from Solution," *Trans. Inst. Chem. Eng.*, **15**; "Dielectric Constants, Rates of Gaseous Reactions, Osmotic Pressure," *Z. f. phys. Chem.* (Cohen Festscrift). (*Signed by*) F. G. Donnan, S. Barratt, C. W. Bonniksen.

POLLARD, ALFRED, Hulme Hall, Victoria Park, Manchester. British. Research Student. B.Sc., Honours Chem., 1st Class, m/c 1926. Research in Organic Chemistry under the supervision of Prof. R. Robinson, F.R.S., 1926— . "The Nitration of *s*-Methylthioguaiacol," *J.C.S.*, 1926, 3090; "Nitration of Benzylpiperidine," etc. (in the press). (*Signed by*) R. Robinson, A. Lapworth, E. W. Wignall, H. Raymond Ing.

ROACH, WILLIAM ARTHUR, Ford House, High Street, West Malling, Kent. British. Biochemist to the East Malling Research Station. B.Sc. (Lond.)., A.R.C.S., D.I.C., A.I.C. 1916–18, Assistant Chemist in the Chemical Warfare Dept. of the Ministry of Munitions; 1919–27, Assistant Research Chemist Rothamsted Experimental Station; at present Biochemist to the East Malling Research Station. I have published papers in the *Annals of Applied Biology*, *Biochemical Journal*, etc. (*Signed by*) H. F. Harwood, H. J. T. Ellingham, A. G. Pollard.

RÖRDAM, HANS NICOLAI KELLERMANN, Copenhagen K., Polyteknisk Laereanstalt, Sölvgade 83. Danish. Lecturer in Chemistry at the Royal Military High School. Assistant at the Chem. Laboratory of the Polytechnical Institute, Copenhagen. D.Sc. at the University of Copenhagen.

" Organic Oxonium Compounds," *J. Amer. Chem. Soc.*, 1915, **37**, 557; " Der Einfluss von Substituenten in *ortho-*, *meta-*, und *para*-Stellung auf die Affinität der Benzoësäure," *Z. für phys. Chemie*, 1921, **99**, 474. These two papers have also been published in the " Memoirs of the Royal Danish Society of Sciences." " Studies on Activity " (Dissertation for the degree of D.Sc., Copenhagen, 1925). Textbooks of Physical Chemistry (1925) and of Organic Chemistry (1927) for the senior classes of the Royal Military High School. (*Signed by*) Chr. Winther, Einar Biilmann, H. Baggesgaard Rasmussen.

SCOTT, ROLAND, River View, Middleton-One-Row, nr. Darlington. British. Technical Chemist. Three and a half years' Industrial Chemistry. Three years' Research Work. (*Signed by*) W. J. V. Ward, H. Sim Hirst, R. G. Franklin.

SHARP, GLADYS IRENE, 34, Woodhouse Road, Leytonstone, E. 11. British. Student at East London College from Sept. 1925. (*Signed by*) E. E. Turner, E. Roberts, A. Brewin.

SINGH, BABU LAL, The Shree Krishna Deshi Sugar Works, Jhusi, B. and N.W. Ry. P.O. Jhusi, Dist., Allahabad. Indian, Hindu. Industrial Chemist. Was Science teacher in the National Collegiate School, Chapra, for a year; Assistant Chemist in the Western India Prospecting Syndicate, Ltd., Cawnpore, for a year, where I worked on soap, oil, ink, and gur analysis; Industrial Chemist in several sugar factories in Behar and United Provinces for six years. Contributed several scientific articles in Indian monthly magazines. Associate of Sugar Technologists' Association of India. (*Signed by*) S. Dutt, N. R. Dhar, K. P. Chatterjee.

SMITH, HENRY GEOFFREY, 39, Headingley Mount, Headingley, Leeds. British. Research Student. 2nd Class Honours B.Sc., Leeds. Research Student at Leeds University. (*Signed by*) C. K. Ingold, J. W. Baker, C. W. Shoppee.

SMITH, JAMES ANDREW BUCHAN, 35, St. John's Road, Selly Park, Birmingham. British. Research Student in University of Birmingham, B.Sc., Honours in Chemistry (1st). (*Signed by*) W. N. Haworth, H. D. K. Drew, E. L. Hirst.

STOWELL, FLAXNEY PERCIVAL, 10, Grosvenor Mansions, Broad Walk, Buxton, Derbyshire. British. Research Chemist. B.Sc. (1st Class Hons. Chem.), Liverpool. Ph.D., Liverpool. As Aquarium Research Fellow of the Zoological Society of London, 1925–27: *Proc. Zool. Soc. London*, 1925, **82**, 141; *ibid.*, 1926, 245; *ibid.*, 1927, 19; *Jour. Marine Biological Assoc.*, 1927, **14**, 955; one still in printer's hands. McKeown and Stowell, *J.C.S.*, January, 1927, " The Vapour Pressures of Mixtures of (*a*) Methyl Acetate and Water, (*b*) Methyl Acetate, Sucrose, and Water." (*Signed by*) A. Eric J. Vickers, John W. Corran, A. McKeown.

TAYLOR, JOHN, 120, Hurlingham Road, Fulham, London, S.W. 6. English. Student. Hons. B.Sc. (Durham). Research Student at Armstrong College for one year; at present research student under Professor Bone. (*Signed by*) G. R. Clemo, R. D. Haworth, P. L. Robinson, K. N. Welch, Richard Raper.

THOMERSON, LILIAN GERTRUDE, 134, Colchester Road, Leyton, E. 10. Essex. British. B.Sc., London. Student at East London College 1923 onwards. Research Student in Organic Chemistry from 1927 (Sept.). (*Signed by*) E. E. Turner, E. Roberts, A. Brewin.

THOMPSON, HAROLD WARRIS, Trinity College, Oxford. English. Student in Chemistry, Oxford University. Hopes to take Part I, B.A. in June 1928. (*Signed by*) C. N. Hinshelwood, E. J. Bowen, H. Hartley, H. R. Raikes.

THORN, VERA MILLICENT, 37, Steade Road, Sheffield. British. Research

Student. University of Sheffield [Organic Chemistry Dept.]. B.Sc. (Special) Chemistry Honours II. 1926, Engaged on Research on Derivatives of Piperazine. (*Signed by*) T. S. Moore, M. Boyle, W. P. Wynne.

TIPPER, CLARENCE CYRIL, 6, Rochester Road, Southsea, Portsmouth. British. Certificated Teacher. B.Sc., London University. Reading for Hons. Chemistry (Special Degree, London) at Birkbeck College, London. (*Signed by*) Herbert C. Dane, Walter H. Watson, John Wilson.

TIPSON, ROBERT STUART, 111, Allesley Road, Coventry. British. Research Student. B.Sc., 1st Class Honours Chemistry (Birmingham). (*Signed by*) W. N. Haworth, H. D. K. Drew, E. L. Hirst.

TRAILL, RALPH CUTHBERT, Clare College, Cambridge. British. Student. M.Sc. (Melbourne). Lately Research Student, Melbourne. (*Signed by*) Harold A. Scarborough, W. A. Waters, R. P. Cook.

VEAZEY, WILLIAM REED, Case School of Applied Science, Cleveland, Ohio. United States of America. Professor of Chemical Engineering. A.B., Westminster College (Pa.), 1903. Ph.D., Johns Hopkins University, 1907. Member Board of Directors, Dow Chemical Company, Midland, Michigan. Author of following U.S. Patents on Magnesium and its Alloys and Metallic Sodium: 1,374,968; 1,375,330; 1,377,374; 1,374,968; 1,334,179; 1,334,193; 1,558,066; 1,515,082; 1,476,192. (*Signed by*) Olin F. Tower, J. L. R. Morgan, James Kendall.

WAHBI, AHMED KAMEL, 329, Gt. Western Street, Rusholme, Manchester. Egyptian. Third year (Honours) Chemistry Student, University of Manchester. I desire to receive the publications of the Society in order to keep in touch with the progress of research. (*Signed by*) Arthur Lapworth, Frederick Challenger, L. Klein, Alex. Robertson.

WARD, ANGUS FITZCHARLES HENDERSON, 7, Manor Street, Cambridge. British subject by birth. Research Student. B.A. (1st Class) (Cambridge). B.Sc. (1st Class) (London). Amy Mary Preston Read Scholar in the University of Cambridge and Holder of D.S.I.R. Research Grant. Late Scholar of Jesus College, Cambridge; Fellow of the Cambridge Philosophical Society. "On the Heat of Adsorption of Oxygen on Charcoal" (accepted but not yet published), by Ward and Rideal. (*Signed by*) Eric K. Rideal, W. H. Mills, T. M. Lowry.

WEBB, JOHN IVOR, 12, Third Avenue, Selly Park, Birmingham. British. Research Student, University of Birmingham. B.Sc., Honours in Chemistry (1st). (*Signed by*) W. N. Haworth, H. D. K. Drew, E. L. Hirst.

WHITTAM, RICHARD, 120, Walmersley Road, Bury, Lancashire. British. Research Student. Assistant in Research Dept. of British Dyestuffs Corp., 1920–27. Now doing research work (Chemistry) at Manchester University for Ph.D. Sitting for London External B.Sc. (Hons.), 1928. (*Signed by*) Arthur Lapworth, E. H. Rodd, Percy Chorley.

WILLIAMS, DAVID MATTHEW, "Cranbrooke," Bridge Street, Aberystwyth. British. Assistant Lecturer in Chemistry. B.Sc. (Wales). Ph.D. (Wales). 1924–27, Senior Chemistry Master, Ebbw Vale County School. 1927, Assistant Lecturer in Chemistry, University College of Wales, Aberystwyth. (*Signed by*) T. Campbell James, C. R. Bury, L. J. Hudleston.

The following Certificates have been authorised by the Council for presentation to ballot under Bye-Law I (2):

BARTON-HOBBS, GEORGE ERNEST, "Braemar," 236, Chelmsford Road, Durban, Natal, South Africa. English. Analytical Chemist, Natal Cane By-Products, Ltd., Merebank, Natal, South Africa. I.C.S. Diploma,

"Chemistry and Chemical Technology," in Durban, South Africa. Lab. Asst. Govt. Natal Herb. and Physiological Laboratory, Durban. Special sugar, soil, and general analysis, general laboratory and photography work, etc. Asst. Chem. Amatikulu Sugar Mill, Zululand. General Sugar and Mill. Post seven years, Chemist, Natal Cane By-Products, Ltd. Manufacturer, Natalite motor fuel, Alc., Abs., etc. Research work in fermentation, fertilizer from still refuse, motor fuels, etc. General analysis, etc. (*Signed by*) Chas. D. Golding.

BETTI, MARIO, Istituto di Chimica generale, R. Università, Bologna (Italy). Italian. Prof. of General Chemistry. Director of the Chem. Inst. Chem. Doctor (R. Univers., Pisa, 1897). Researches on general, physical and organic chemistry, published in *Gazzetta chimica italiana, Rendiconti R. Accad. Lincei*, etc., from 1897 to 1927. *J.C.S.*, 1916, **109**, 424–28. (*Signed by*) Arnaldo Piutti.

VAN DUIN, CONSTANT FREDERIK, 34, Nieuwe Gracht, Utrecht, Holland. Dutch. Ph.D., Utrecht (Holland), 1918. Formerly assistant for Organic Chemistry at the University of Utrecht, chemist at the munition factory at Zaandam, chief chemist of the chemical factory "Naarden" at Naarden, and Dutch Ramsay Fellow. Author of 35 papers in *Rec. trav. chim., Chemisch Weekblad, J. Chem. Soc., J. Amer. Chem. Soc., Z. physik. Chemie*, and *Verslagen Kon. Akad. van Wetenschappen Amsterdam*. (*Signed by*) Ernest Cohen.

HUGHES, THOMAS ROBERT, 47, Colin St., West Perth, Australia. British. Industrial Chemist. Student Member Australian Chemical Institute. Four years Chemical Student, Perth Technical School. Five years Chief Chemist and Works Manager of Messrs. Plaimar, Ltd., Essential Oil Distillers, Perth, West Australia. Research work has been, and is being done, in connection with the above Firm on the chemical composition and commercial production of Australian Essential Oils, particularly Sandalwood Oil. (*Signed by*) Edward S. Simpson, Albert J. Simons.

LENZE, FRITZ, Berlin, Wilmersdorf, Eisenzahnstrasse No. 5. German (Deutsch). Director of the Chemisch-Technischen Reichsanstalt, Berlin, Jungfernheide, Postamt Plötzensee. Professor Dr. Besides the function of Director of the Chemisch-Technischen Reichsanstalt, author of several treatises, chiefly on explosives and on cellulose, all published in German scientific papers, viz.: (1) *Berichte der Deutschen chemischen Gesellschaft*, 1898, **31**, 68–90; (2) *Zeitschrift für das gesamte Schiess- u. Sprengstoffwesen*, **14**, 297, 315, 331, 346, 377, and 395; (3) *Journal für praktische Chemie*, **101**. (1) *J.C.S.*, 1898, **74**, i, 227; (2) (No reference to be found.); (3) 1921, **119**, i, 163. (*Signed by*) Robert Robertson.

LEVI, GIORGIO RENATO, Viale Romagna 37, Milano, Italy. Italian. Prof. of Physical Chemistry, University of Milan. Dr.chem. (Padova). Researches in physical, inorganic, and organic chemistry (Chemical applications of *X*-Rays, Chlorites, Dyestuffs). (*Signed by*) Giuseppe Bruni.

PROCEEDINGS

OF THE

CHEMICAL SOCIETY.

Ordinary Scientific Meeting, Thursday, February 2nd, 1928, at 8 p.m., Professor H. BRERETON BAKER, C.B.E., D.Sc., F.R.S., President, in the Chair.

Certificates were read for the first time in favour of:

George Wilson Patton, B.Sc., 36, Arlington Street, Anlaby Road, Hull.
Donald Henry Richardson, Ph.D., M.Sc., A.I.C., 4, The Crossways, Onslow Village, Guildford.
Tiruvenkata Rajendra Seshadri, M.A., Chemical Department, The University, Manchester.
Alfred Tingle, B.Sc., Ph.D., Department of National Revenue, Ottawa.
Leonard Arthur Warren, 16, Bourne Hill, Palmers Green, N. 13.
Roy Basil Waters, 124, Kingsland Road, Plaistow, E. 13.
William Leonard Whiteley, B.Sc., 87, St. Mark's Road, Mitcham.
Richard Llewelyn Wilson, M.Sc., Gorphwysfa, Caersws, Montgomery.
Reginald Joseph Winterton, 30, Austin Street, King's Lynn.

The following papers were read:

"Some experiments on diffusion in solid metals." By J. W. JENKIN and C. H. DESCH.

"The alkaloids of some Indian aconites: *Aconitum rotundifolium*, A. Balfourii, and *A. deinorrhizum*." By T. A. HENRY and T. M. SHARP.

"The synthesis of *meso*-alkyl and *meso*-aryl anthracene derivatives. Part III." By E. DE B. BARNETT and J. W. COOK.

Ordinary Scientific Meeting, Thursday, February 16th, 1928, at 8 p.m., Professor H. BRERETON BAKER, C.B.E., D.Sc., F.R.S., President, in the Chair.

The PRESIDENT referred to the loss sustained by the Society, through death, of the following Fellows:

	Elected.	Died.
Herbert Edward Burgess	Feb. 15th, 1894.	Oct. 24th, 1927.
Richard Oxley Burland	Dec. 2nd, 1897.	Jan. 27th, 1928.
Henry Couldrey.....	June 16th, 1892.	Aug. 13th, 1927.

Mr. C. A. Waters was formally admitted a Fellow of the Chemical Society.

Certificates were read for the first time in favour of :

Sudhir Chandra Basu, M.Sc., 21, Cromwell Road, South Kensington, S.W. 7.
Frederick Frank Glasspool, B.Sc., Victoria College, Bath.
Alice Corfield Kellett, B.Sc., 103, Claremont Road, Pendleton, Manchester.
Spencer Claude Gascoine Moon, Medway, Amiens Street, Gladesville, N.S.W.
Edward William James Moore, B.Sc., A.I.C., 307, Blackburn Road, Haslingden, Rossendale, Lancs.
Charles Earl Mullin, M.Sc., Clemson College, South Carolina, U.S.A.
Walter Weston Webb, Ph.D., B.Sc., A.I.C., Fairmead Cottage, Spring Grove, Loughton.

A certificate has been authorised by the Council for presentation to ballot under Bye-Law I (2) in favour of :

Edward Charles Haddon, Medical Research Laboratories, Entebbe, Uganda.

Dr. J. G. F. Druce and Dr. J. L. Simonsen were elected Scrutators, and a ballot for the election of Fellows was held. The following were subsequently declared elected as Fellows :

Stanley Baker, M.Sc., Ph.D.
Harold Hayden Barber, B.Sc., F.I.C.
George Ernest Barton-Hobbs.
Mario Betti, Dr.Chem.
Harold Graham Bott, B.Sc.
Reginald Bowsher, B.Sc.
Basil Butterworth, B.Sc.
Jessie Cattermole.
Bibhuti Bhuson Chaudhuri, M.Sc.
Jacob Davis Cohen, B.Sc., A.C.G.F.C.
Moses Leverock Crossley.
William Fraser Donald.
Constant Frederick Van Duin, Ph.D.
Tom Farrar.
Geoffrey William Fenton, B.Sc.
George William Ferguson.
James Flint, M.C.
Frank Lathe Gilbert, B.Sc.
Charles Frederick Goodeve, M.Sc.
Marion Gosset, B.Sc., A.R.C.S.
Edgar Beattie Grant.
Leslie George Groves, B.Sc.
Herbert Charles Gull, B.Sc.
Thomas Hagyard, B.Sc.
Horace Arthur Hampton, B.Sc.
Donald Holroyde Hay, B.Sc.
Clive Whelpton Holman, A.M.I.Mech.E.
Marshall Holmes, M.Sc.
Theodora Mary Holmes, B.Sc., A.R.C.S.
James Hood.
Miriam Ivy Horton.
Thomas Robert Hughes.
Arthur Jackson, B.Sc.
Robert Gilbert James, B.Sc., A.I.C.
Anantrao Ramchandra Kagal, B.A., B.Sc.
Herbert Davenport Kay, Ph.D., D.Sc.
Frank Eugene Lathe, B.A., M.Sc.
Kenneth Hugh Lauder, B.Sc.
Abraham Learner, B.Sc.
Fritz Lenze.
Alfred William Leonard, B.Sc.
Giorgio Renato Levi, Dr.Chem.
John Vaughan Loach, B.Sc.
John Longwell, M.Sc., A.I.C.
Arthur Bertram Edmund Lovett, B.Sc.
Charles George Lyons, B.A.
Birendra Keshary Mandal.
Hamilton Ryoichi Matsuda.
Thomas Henry Morton, B.Sc.
Leslie Wallace Mullinger.
William George Painton, B.Sc., A.I.C.
Eric Pascal, M.A.
Walter A. Patrick, B.S., Ph.D.
Alfred Pollard, B.Sc.

William Arthur Roach, B.Sc., A.R.C.S., A.I.C.
Hans Nicolai Kellermann Rördam, D.Sc.
Roland Scott.
Gladys Irene Sharp.
Babu Lal Singh.
Henry Geoffrey Smith, B.Sc.
James Andrew Buchan Smith, B.Sc.
Flaxney Percival Stowell, B.Sc., Ph.D.
John Taylor, B.Sc.
Lilian Gertrude Thomerson, B.Sc.
Harold Warris Thompson.
Vera Millicent Thorn, B.Sc.
Clarence Cyril Tipper, B.Sc.
Robert Stuart Tipson, B.Sc.
Ralph Cuthbert Traill, M.Sc.
William Reed Veazey, A.B., Ph.D.
Ahmed Kamel Wahbi.
Angus Fitzcharles Henderson Ward, B.A., B.Sc.
John Ivor Webb, B.Sc.
Richard Whittam.
David Matthew Williams, B.Sc., Ph.D.

The following papers were read :

"Studies in China wood oil. Part II. The oxidation of β-elæostearic glyceride." By R. S. Morrell and S. Marks.

"Cryoscopic evidence of compound formation in mixtures of organic liquids." By W. M. Madgin, J. B. Peel, and H. V. A. Briscoe.

"The preparation and properties of selenophene and certain halogen derivatives of selenophene." By H. V. A. Briscoe and J. B. Peel.

"A further case of the spontaneous resolution of externally compensated mixtures." By L. Anderson and D. W. Hill.

ANNUAL GENERAL MEETING.

The Annual General Meeting will take place on Thursday, March 22nd, 1928, at 4 p.m., when the retiring President, Professor H. Brereton Baker, C.B.E., D.Sc., F.R.S., will deliver his address.

ANNIVERSARY DINNER.

The Anniversary Dinner of the Society will be held at the Hotel Victoria, King Edward VIIth Rooms, Northumberland Avenue, W.C. 2, on Thursday, March 22nd, 1928 (the day of the Annual General Meeting) at Seven for Half-past Seven o'clock.

The Presidents of the Belgian, Danish, Dutch, Finnish, Norwegian, and Swedish Chemical Societies, the President of the Union Internationale, and other distinguished guests have been invited by the Council to the Dinner, and it is hoped that there will be a large and representative gathering of Fellows present.

Tickets, price Twelve Shillings and Sixpence (12*s.* 6*d.*) each, including gratuities to waiters, can be obtained from the Assistant

Secretary, Chemical Society, Burlington House, Piccadilly, W. 1. A remittance for the number of tickets required, made payable to S. E. Carr, must accompany each application.

List of Papers, or Abstracts thereof, received between January 19th and February 16th, 1928. (This List does not include the titles of papers, or abstracts thereof, which have been read at an Ordinary Scientific Meeting, or which have appeared in the Journal.)

"Polysaccharides. Part I. The structure of inulin." By W. N. HAWORTH and A. LEARNER.

"A new pipette." By H. N. RIDYARD.

"Silver nitrate concentration cells in acetonitrile and benzonitrile." By F. K. V. KOCH.

"The burning of carbon disulphide. Part II. The velocity of the uniform movement of flame in carbon disulphide–second combustible–air mixtures." By A. G. WHITE.

"The precipitation of cadmium sulphide from aqueous solutions of cadmium chloride in the presence of hydrochloric acid and other chlorides. Part II. Neutral salt effect." By S. KRISHNAMURTI.

"Some miscibility relations of acetic anhydride." By D. C. JONES and H. F. BETTS.

"Molecular volumes at absolute zero." By W. BILTZ.

"Proteolytic enzymes in brewers' yeast." By D. A. RUDDLE.

"Lead subacetate solution ('Goulard's extract') and its reaction with phenols." By C. S. GIBSON and E. MATTHEWS.

"The intermolecular condensation of acetylmethylanthranilic acid by means of phosphorus pentachloride and the formation of a complex *iso*cyanine dye." By I. M. HEILBRON, S. L. HOLT, and F. N. KITCHEN.

"Stereoisomerism in polycyclic systems. Part IV. Two stereoisomerides of 2 : 3 : 4 : 5 : 12 : 13-hexahydroquinindene." By W. H. PERKIN and S. G. P. PLANT.

"A new synthesis of 4-amino-3-hydroxyphenylarsinic acid." By I. E. BALABAN.

"Some properties and reactions of β-chloroethyl, β-cyanoethyl, and β-carbethoxyethyl toluene-*p*-sulphonates, and an extension of the Friedel–Crafts reaction." By G. R. CLEMO and E. WALTON.

"Equilibrium in binary systems composed of ethylenediamine and phenols." By N. A. PUSHIN and L. SLADOVICH.

"Benzoic esters and electronic affinities of radicals. Part I." By A. ZAKI.

"Constituents of *Myoporum lætum*, Forst. (The "Ngaio"). Part III. The oxide rings of ngaione, an isomeride of ngaiol, and a sesquiterpene monoxide." By F. H. MCDOWALL.

"The influence of groups and associated rings on the stability of certain heterocyclic systems. Part IV. The substituted butyro- and valero-lactones." By S. S. G. SIRCAR.

"Selenium oxyfluoride." By E. B. R. PRIDEAUX and C. B. COX.

"The nitration of mixed *m*-dihalogenobenzenes." By H. A. MAYES and E. E. TURNER.

"The competitive interaction of alkyl and aryl halides with magnesium." By H. W. RUDD and E. E. TURNER.

"The isomerism of the styryl alkyl ketones. Part IV. 4-Hydroxy- and some derivatives of 2-hydroxy-styryl alkyl ketones." By A. MCGOOKIN and D. J. SINCLAIR.

"The isomerism of the styryl alkyl ketones. Part V. 2-Hydroxy-styryl *tert.*-butyl, *iso*butenyl, and phenyl ketones." By A. MCGOOKIN and D. J. SINCLAIR.

"The constitution of irigenin and iridin. Part I." By W. BAKER.

"The condensation of certain aldehydes with ketones of the morphine group." By J. M. GULLAND.

"The mechanism of the degradation of fatty acids by mould fungi. Part I." By T. K. WALKER and P. D. COPPOCK.

"Nature of the alternating effect in carbon chains. Part XXV. Activation of extended conjugated systems." By J. W. BAKER.

"A test for caryophyllene." By D. T. GIBSON.

"The action of bromine water on certain olefinic acids." By J. READ and W. G. REID.

"Mobile-anion tautomerism. Part I. A preliminary study of the conditions of activation of the three-carbon system, and a discussion of the results in relation to the modes of addition to conjugated systems." By H. BURTON and C. K. INGOLD.

"Equilibrium in solutions. A note on 'the activity theory of reaction velocity.'" By W. F. K. WYNNE-JONES.

"The nature of the hydroxyl groups of hydroxyanthraquinones." By A. GREEN.

"The complex salts of bivalent platinum with $\alpha\beta\gamma$-triaminopropane." By F. G. MANN.

"On the chemical individuality of humulene." By A. C. CHAPMAN.

"Chloroamines as halogenating agents. Iodination by a chloroamine and an iodide." By A. E. BRADFIELD, K. J. P. ORTON, and I. C. ROBERTS.

"The action of cuprous cyanide and methyl iodide." By E. G. J. HARTLEY.

"The constitution of thebenine." By J. M. GULLAND and C. J. VIRDEN.

"The unsaponifiable matter from the oils of Elasmobranch fish. Part IV. The establishment of the structure of selachyl and batyl alcohols as monoglyceryl ethers." By I. M. HEILBRON and W. M. OWENS.

"Note on a volatile platinum compound." By R. C. MENZIES.

"Orientation effects in the diphenyl series. Part VI. The supposed isomerism of the dinitrotolidines." By R. J. W. LE FÈVRE and E. E. TURNER.

"Synthetical experiments in the aporphine group. Part II. A synthesis of bulbocapnine methyl ether." By J. M. GULLAND and R. D. HAWORTH.

"The system sodium–tin." By W. HUME-ROTHERY.

PROCEEDINGS

OF THE

CHEMICAL SOCIETY.

Extra Meeting held on Thursday, February 23rd, 1928, at 8 p.m., Professor H. BRERETON BAKER, C.B.E., D.Sc., F.R.S., President, in the Chair.

Professor A. Fowler, F.R.S., delivered his Lecture entitled "Spectra and Atoms." A vote of thanks to the Lecturer, proposed by the Rt. Hon. Lord Rayleigh, F.R.S., and seconded by Professor H. E. Armstrong, F.R.S., was carried with acclamation, Professor Fowler making acknowledgment.

Ordinary Scientific Meeting, Thursday, March 1st, 1928, at 8 p.m., Professor H. BRERETON BAKER, C.B.E., D.Sc., F.R.S., President, in the Chair.

The PRESIDENT referred to the loss, sustained by the Society, through death on December 28th, 1927, of Mr. Charles James Waterfall, who was elected a Fellow on November 16th, 1882.

The following list of nominations for vacant places on the Council was read from the Chair:

President (one vacancy): JOCELYN F. THORPE.
Treasurer (one vacancy): T. SLATER PRICE.
Secretary (one vacancy): T. S. MOORE.
Vice-Presidents who have filled the office of President (three vacancies): H. BRERETON BAKER, WILLIAM H. PERKIN, and SIR JAMES WALKER.
Vice-Presidents who have not filled the office of President (two vacancies): WILLIAM H. MILLS, JAMES C. PHILIP.

Ordinary Members of Council:

(*a*) Town Members, *i.e.* those resident within 50 miles of Charing Cross (six vacancies): WILLIAM A. BONE, HAROLD KING, JOHN L. SIMONSEN, SAMUEL SUGDEN, HENRY TERREY, and MARTHA A. WHITELEY.

(*b*) Country Members, *i.e.* those resident beyond 50 miles from Charing Cross (two vacancies): WILLIAM M. CUMMING, NEVIL V. SIDGWICK.

The following were formally admitted Fellows of the Chemical Society: J. Masson Gulland, L. W. Mullinger, T. M. Holmes, M. Gosset, J. W. T. Jones.

Certificates were read for the first time in favour of:

Frank Bryans, M.Sc.Tech., 14, Church Street, Pendlebury, Manchester.
Julian Paul Fraser, c/o The Burmah Oil Co., Ltd., Syriam, Burma.
John Gaius Ashwell Griffiths, B.A., A.I.C., Gable Beach, Coppice Avenue, Great Shelford, Cambridge.
Chuan-Ling Liang, B.A., M.Sc., 17, West Compound, Tsing Hua University, Peking.
Charles Edward Leslie Lucas, A.I.C., 27, Park Hill, Ealing, W. 5.
Glyn Owen, M.Sc., Dalton Hall, Victoria Park, Manchester.
Alex Rae, The Trees, Thingwall Road, Wavertree, Liverpool.
Reginald Harvey Spiller, A.R.C.S., A.I.C., Stonewall, Limpsfield, Surrey.

The following papers were read:

"The complex salts of bivalent platinum with $\alpha\beta\gamma$-triaminopropane." By F. G. MANN.

"The constitution of thebenine." By J. M. GULLAND and C. J. VIRDEN.

"Properties of conjugated compounds. Part V. The constitution of the sodio-esters derived by the Michael reaction as related to the additive process." By E. H. FARMER and C. D. LANGFORD.

"Properties of conjugated compounds. Part VI. The hydrogenation of certain extended heterogeneous systems." By J. T. EVANS and E. H. FARMER.

Ordinary Scientific Meeting, Thursday, March 15th, 1928, at 8 p.m., Professor H. BRERETON BAKER, C.B.E., D.Sc., F.R.S., President, in the Chair.

The PRESIDENT referred to the loss sustained by the Society, through death, of the following Fellows:

	Elected.	Died.
John F. V. Isaac	Dec. 15th, 1892.	Dec. 21st, 1927.
James Taylor	June 17th, 1880.	Dec. 14th, 1927.

The following were formally admitted Fellows of the Chemical Society: Wm. G. Painton, J. Cattermole, R. A. Morton.

Certificates were read for the first time in favour of :

Alfred Ernest Barratt, White House, Hawthorn Drive, Evington, Leicester.
Henry Scott Buckland, Jesus College, Cambridge.
Bertrand Stockdale Clarke, 62, Algers Road, Loughton.
Donald Vernon Ivins, No. 208 Squadron, Royal Air Force, H.Q. Cairo Brigade, Helwân, Cairo.
Ralph Oliver Phillips, M.Sc., Forestal Central Laboratories, Harpenden.
Vaidyanathier Ramaswami, M.Sc., 18, Luxembourg Gardens, W. 6.
Devanahalli Krishna Rao, B.Sc., c/o The Commonwealth Trust Ltd., Calicut P.O., India.

Certificates have been authorised by the Council for presentation to ballot under Bye-Law I (2) in favour of :

Yuoh Fong Chi, Yale University, New Haven, U.S.A.
Frederick Hardy, Windyridge, Curepe, Trinidad.

The following papers were read :

" Mobile-anion tautomerism. Part I. A preliminary study of the conditions of activation of the three-carbon system, and a discussion of the results in relation to the modes of addition to conjugated systems." By H. BURTON and C. K. INGOLD.

" Studies of dynamic isomerism. Part XXVII. The absorption-spectra of prototropic compounds. Physical properties of the enolic and ketonic forms of benzoylcamphor." By T. M. LOWRY, C. A. H. MACCONKEY, and H. BURGESS.

" The parachor and chemical constitution. Part IX. Boron compounds." By J. J. ETRIDGE and S. SUGDEN.

" Observations on the passivity of metals." By E. S. HEDGES.

List of Papers, or Abstracts thereof, received between February 16th and March 15th, 1928. (This List does not include the titles of papers, or abstracts thereof, which have been read at an Ordinary Scientific Meeting, or which have appeared in the Journal.)

" Internal equilibrium in liquid sulphur. Part I." By D. L. HAMMICK, W. R. COUSINS, and E. J. LANGFORD.

" The ring structure of sugars. The isolation of a new form of lyxose." By W. N. HAWORTH and E. L. HIRST.

" The condensation of chloral with substituted phenols." By F. D. CHATTAWAY and F. CALVET.

" The reduction of selenious acid." By L. M. CLARK.

" Some dinitroethylbenzenes." By O. L. BRADY, J. N. E. DAY, and P. S. ALLAM.

" Imide ring closure in derivatives of diketosuccinic acid phenylosazone." By F. D. CHATTAWAY and W. G. HUMPHREY.

"The chlorination of anilides. *N*-Chlorination and *C*-chlorination as simultaneous side reactions." By K. J. P. Orton, F. G. Soper, and G. Williams.

"The photodecomposition of triphenylmethyl." By S. T. Bowden and W. J. Jones.

"Cyclic disulphides derived from diphenyl." By H. J. Barber and S. Smiles.

"A method for the photographic examination of moving flames." By A. G. White.

"Conversion of hydroaromatic into aromatic compounds. Part II. Action of bromine on 5-chloro- and 5-bromo-1-phenyl-Δ^4-*cyclo*hexen-3-one." By L. E. Hinkel and D. H. Hey.

"Equilibrium in electrolyte solutions and the reaction velocity equation." By F. G. Soper.

"The action of nitrous acid on amino-compounds. Part I. Methylamine and ammonia." By T. W. J. Taylor.

"Equilibrium diagram of the system antimony–arsenic." By Q. A. Mansuri.

"The influence of structure on the keto-enol change. Part I. The velocity of enolisation of some substituted amides of aceto-acetic acid." By R. H. Spiller and R. W. West.

"On the oxidation of *n*-hexane." By M. Brunner and E. K. Rideal.

"Some experiments in intensive drying." By R. H. Purcell.

"The action of aniline on *d*-glutamic acid." By W. H. Gray.

"The tautomerism of *cyclo*pentadienes. Part I. Some derivatives of methyl*cyclo*pentadiene." By F. R. Goss and C. K. Ingold.

"Acid and salt effects in catalysed reactions. Part XIII. Inert salt effects in the catalytic action of acids." By H. M. Dawson and A. Key.

"Reactions of carbohydrazide. Part II." By A. M. Munro and F. J. Wilson.

"The determination of volatile matter in coke." By F. J. Eaton and S. Pexton.

"The chlorination of anilides. Part IV. The significance of velocity measurements in relation to the problem of benzene substitution." By A. E. Bradfield and B. Jones.

"The constitution of phenolphthalein. Part I. Preparation of some compounds of the phthalein type." By H. Lund.

"The hypothesis of valency-deflection." By C. K. Ingold and J. F. Thorpe.

"Ionic equilibrium in colloidal solutions." By H. D. Murray.

"The conductivity of copper hydrosols." By H. D. Murray.

"The pectin and hemicelluloses of the flax plant." By S. T. HENDERSON.

"The preparation of 4 : 4'-dinitrobenzil." By F. D. CHATTAWAY and E. A. COULSON.

"On active nitrogen. Part V. The decay of the nitrogen afterglow." By E. J. B. WILLEY.

"The chemistry of polycyclic structures in relation to their homocyclic unsaturated isomerides. Part IX. The effect of the *spirocyclo*pentane grouping on the five-carbon intra-annular tautomeric nucleus." By F. R. GOSS.

"Some thiazole derivatives. Part II." By H. W. STEPHEN and F. J. WILSON.

"A quantitative study of the oxidation of methyl oleate and elaidate by hydrogen peroxide in presence of acetic acid." By T. P. HILDITCH and C. H. LEA.

"Optical activity and the polarity of substituent groups. Part VIII. Growing chain effects and the ortho-effect in benzoic esters." By H. G. RULE, W. HAY, and J. PAUL.

"The mechanism of tautomeric interchange and the effect of structure on mobility and equilibrium. Part II. Ring-chain tautomerism in its relation to the mutarotation of the sugars." By J. W. BAKER.

"The reaction of bromine with aliphatic acids. Part II. The relative speeds of bromination of acetyl bromide and acetyl chloride." By H. B. WATSON.

"The condensation of ketones with ethyl acetoacetate." By L. G. JUPP, G. A. R. KON, and E. H. LOCKTON.

PROCEEDINGS

OF THE

CHEMICAL SOCIETY.

THE Anniversary Dinner of the Chemical Society was held at the Hotel Victoria (Edward VII Rooms) on Thursday, 22nd March, 1928, at 7 for 7.30 p.m.; the President, Professor J. F. THORPE, C.B.E., D.Sc., F.R.S., was in the Chair, and the following Fellows and guests, numbering 234, were present:

Abbott, Miss A.
Armstrong, Miss N.
Ashby, E.
Austin, Bertram.
Austin, Mrs. Bertram.
Baker, Miss Audrey.
Baker, H. Brereton, C.B.E., F.R.S., *Past-President.*
Baker, Mrs. H. Brereton.
Baker, S.
Bedson, P. Phillips.
Bedson, Mrs. S. Phillips.
Bennett, Miss D. M.
Bolton, E. R.
Bolton, Mrs. E. R.
Bowsher, R.
Bramley, A.
Brewer, F. M.
Briggs, Frank R.
Briggs, Mrs. Frank R.
Briggs, Harold, M.P.
Briggs, Mrs. Harold.
Burch, W. J. N.
Cain, Miss E.
Caney, Mrs. J. G.
Carlton, Miss M.
Carr, Francis H., C.B.E., *President, The Society of Chemical Industry.*
Carr, Mrs. F. H.
Carr, S. E., *Assistant Secretary.*
Carr, Mrs. S. E.
Chapman, A. W.
Chapman, Mrs. A. W.
Chattaway, F. D., F.R.S.
Chelmsford, The Rt. Hon. Viscount, G.C.S.I., G.C.M.G., G.C.I.E., G.B.E.
Clifford, F. W., *Librarian.*
Coates, J. E., O.B.E.
Cohen, Ernst, For.Mem.R.S., *President, Union Internationale de la Chimie Pure et Appliquée, and also representing the Nederlandsche Chemische Vereeniging.*
Cooper, C. J. A.
Corder, B. J.
Corder, Mrs. B. J.
Crowther, E. M.
Crowther, Mrs. E. M.
Daily Telegraph.
Desch, C. H., F.R.S., *President, The Faraday Society*
Dicksee, Sir Frank, K.C.V.O., *President, The Royal Academy of Arts.*
Donald, Miss G. H.
Donnan, F. G., C.B.E., F.R.S., *Foreign Secretary.*
Donnan, Miss J. E.
Drummond, J. C.
Drummond, Mrs. J. C.
Dyer, B.
Dyer, Mrs. B.
Eccott, E. N.
Edgerton, P.
Edgerton, Mrs. P.
Ehrhardt, Ernest F.
Ehrhardt, Mrs. Ernest.
Eldridge, A. A.

Eldridge, Mrs. A. A.
Ellingham, H. J. T.
Emeléus, H. J.
Ende, C. L. von.
Ewbank, Miss E. K.
Farmer, E. H.
Fass, E.
Findlay, A.
Fitzmaurice, R., R.N., D.S.O., *Vice-President, Chemical Warfare Committee.*
Forbes, C. M., R.N., D.S.O., *Director of Naval Ordnance.*
Forster, Miss E.
Fox, J. J., O.B.E.
Freeth, F. A., O.B.E., F.R.S.
Gamble, F. W.
Gibb, Sir Alexander, G.B.E., C.B., *President, The Institution of Chemical Engineers.*
Gibson, C. S., O.B.E., *Secretary.*
Gilling, C.
Gillman, Lt.-Gen. Sir Webb, K.C.B., K.C.M.G., D.S.O., *Master-General of the Ordnance.*
Goggs, A. B.
Gray, W. H.
Gregory, Sir Richard.
Gulland, J. Masson.
Gulland, Mrs. J. Masson.
Hamer, F. E.
Hamer, Miss F. M.
Hamer, J. C.
Hamer, S. H.
Haworth, W. N.
Henry, T. A.
Henry, Mrs. T. A.
Hewitt, J. T., F.R.S.
Hill, Charles A., *Chairman, The Association of British Chemical Manufacturers.*
Hinchley, J. W.
Hinks, E., M.B.E., *President, Society of Public Analysts.*
Hodgkin, A. E., M.C.
Hodgkin, Mrs. A. E.
Holland, Sir Thomas H., K.C.S.I., K.C.I.E., F.R.S., *Rector, The Imperial College of Science and Technology.*
Holmberg, Bror A. L., *President, Kemistsamfundet, Stockholm.*
Hooker, A. H.
Hooper, D.
Hope, E.
Hunter, R. F.
Ingold, C. K., F.R.S.
James, T. Campbell.
Jarmay, Sir John G., K.B.E.
Jones, Miss E. Cecil.
Jones, G. Cecil.
Jowett, H. A. D.
Keen, W. B.
Kenyon, J.
King, H.
King, Mrs. H.
Kitasato, Z.
Komppa, Gustav, *President, Soumalaisten Kemistien Seura, Helsingfors.*
Kon, G. A. R.
Kon, Mrs. G. A. R.
Lapworth, A., F.R.S.
Lawrence, Sir William, Bart., J.P.
Lefebure, Victor.
Lefebure, Mrs. Victor.
Le Pla, Miss M.
Lessing, R.
Lowndes, J.
Lowry, T. M., C.B.E., F.R.S.
McCombie, H., D.S.O., M.C.
Maclean, Mrs. I. S.
Marlow, G. S. W.
Menzies, R. C.
Menzies, Mrs. R. C.
Micklethwait, Miss F. M. G., M.B.E.
Micklethwait, R. G.
Mitchell, A. D., *Assistant Editor.*
Mitchell, Mrs. A. D.
Mitchell, F. G.
Moller, Miss N.
Mond, The Rt. Hon. Sir Alfred M., Bart., M.P., *President, The Institute of Fuel.*
Mond, Émile.
Moore, T. S., *Secretary.*
Moore, Mrs. T. S.
Morgan, G. T., O.B.E., F.R.S.
Morris, H. J.
Murakami, S.
Nielsen, Harald.
Nielsen, Mrs. Harald.
Nodzu, R.
Page, H. J., M.B.E.
Palmer, R.E., O.B.E., *President, The Institution of Mining and Metallurgy.*

Paravicini, C. R., *Minister for Switzerland.*
Pearson, G. E.
Peel, W. R., D.S.O.
Perkin, A. G., F.R.S.
Perkin, W. H., F.R.S., *Past-President.*
Philip, J. C., O.B.E., F.R.S., *Vice-President.*
Philip, Mrs. J. C.
Philip, W. E.
Phillips, H.
Plenderleith, H. J., M.C.
Plenderleith, Mrs. H. J.
Plimmer, R. H. A.
Pollitt, G. P., D.S.O.
Pope, Sir William J., K.B.E., F.R.S., *Past-President.*
Powell, Mrs.
Press Association.
Price, T. Slater, O.B.E., F.R.S., *Treasurer.*
Price, Mrs. T. Slater.
Purves, T. F., O.B.E., *Vice-President, The Institution of Electrical Engineers.*
Pyman, F. L., F.R.S.
Pyman, Mrs. F. L.
Randerson, W.
Randerson, Mrs. W.
Rideal, E. K., M.B.E.
Rintoul, W., O.B.E.
Rippon, C., J.P.
Rippon, Mrs. C.
Rippon, Miss D. M. L.
Robertson, Sir Robert, K.B.E., *Vice-President.*
Robinson, R., F.R.S., *Vice-President.*
Robinson, Mrs. R.
Rowe, F. M., *Representative of the Society of Dyers and Colourists.*
Rowlands, M. J.
Rutherford, Sir Ernest, O.M., *President, The Royal Society.*
Saastamoinen, A. H., *Minister for Finland.*
Scott, Alexander, F.R.S., *Past-President.*
Scott, Henderson.
Scott, Mrs. Henderson.
Scott, W. D.

Tinkler, Mrs. C. K.
Tizard, H. T., C.B., F.R.S., *Secretary, Department of Scientific and Industrial Research.*
Treadwell, W. D., *President, Société Suisse de Chimie.*
Treadwell, Mrs. W. D.
Trench, E. F. C., C.B.E., *President, The Institution of Civil Engineers.*
Troup, Sir Edward, K.C.B., K.C.V.O., *Chairman, Safety in Mines Research Board.*
Tunstall-Behrens, B.
Tunstall-Behrens, Mrs. B.
Turner, Miss E. G.
Wahl, W., *Vice-President, Finska Kemistsamfundet, Helsingfors.*
Warren, F. L.
Warren, H. Gordon.
Warren, Mrs. H. Gordon.
Waechter, Lady.
Whiteley, Miss M. A., O.B.E.
Widdows, Miss S. T.
Williams, G.

Williams, W. J.
Wood, Miss F. M.
Wynne, Miss D. P.
Wynne, W. P., F.R.S., *Past-President.*
Yeoman, E. W.

The following is a list of the Toasts proposed :—

1. The King.

2. The Queen, the Prince of Wales, and the other Members of the Royal Family.

By The Right Honourable VISCOUNT CHELMSFORD, G.C.S.I., G.C.M.G., G.C.I.E., G.B.E. :—

3. "The Chemical Society," coupled with the name of the President.

By SIR WILLIAM J. POPE, K.B.E., D.Sc., F.R.S., Past-President :—

4. "International Chemistry," coupled with the names of :

(*a*) Professor DR. ERNST COHEN, For.Mem.R.S., President, Union Internationale de la Chimie Pure et Appliquée, and representing the Nederlandsche Chemische Vereeniging.
(*b*) Professor DR. BROR A. L. HOLMBERG, President, Kemistsamfundet, Stockholm.
(*c*) Professor DR. W. D. TREADWELL, President, La Société Suisse de Chimie.
(*d*) Professor W. WAHL, Vice-President, Finska Kemistsamfundet, Helsingfors.

By Professor F. G. DONNAN, C.B.E., D.Sc., F.R.S., Foreign Secretary :—

5. "The Guests," coupled with the names of :

(*a*) SIR FRANK DICKSEE, K.C.V.O., D.C.L., President of the Royal Academy of Arts.
(*b*) Monsieur C. R. PARAVICINI, Minister for Switzerland.
(*c*) The Right Honourable SIR ALFRED M. MOND, Bart., M.P.

After the Loyal Toasts had been honoured, VISCOUNT CHELMSFORD proposed the toast of "The Chemical Society," and said that he belonged to the unfortunate age when the place of science in a liberal education was not sufficiently appreciated and the Science master was a figure of fun. When he went to Winchester in 1881 there was no laboratory in the College, nor did he remember any practical instruction in science. The forty or more years which had passed since then had produced a complete revolution

in the outlook towards scientific teaching. That revolution was due to constant pressure exerted by such a Society as the Chemical Society on public opinion.

Viscount Chelmsford referred to the fact that he was President of the Miners' Welfare Fund, which had contributed so much towards the endowment of research. The achievements of chemistry afforded that benefit to the common life which he who runs might read.

The PRESIDENT, Professor J. F. THORPE, responding, thanked Lord Chelmsford on behalf of the Society for the way in which he had proposed the toast. The Fellows knew Lord Chelmsford as a great viceroy and a great statesman, but he was probably best known to them in his capacity as Chairman of the Miners' Welfare Committee, to which he had referred.

The Miners' Welfare Committee dealt not only with the improvement of the social conditions of the mine workers, but expended a large sum yearly on the prosecution of research into safety conditions in mines. He was therefore glad to see the Chairman of the Safety in Mines Research Board, Sir Edward Troup, here this evening.

During recent years the Society had altered its procedure at the anniversary dinner. Hitherto it had been the custom for the retiring President, although displaced at the meeting during the afternoon, to take the chair at the evening function. The custom had this advantage—that it enabled the outgoing President to give an account of the changes that had been effected during his term of office. Under the existing procedure it devolved upon the new President to do this, and he was glad to have the opportunity of assuring Fellows that all was well with the Society, and that he was sure that all Fellows would agree in expressing their gratitude and regard to his predecessor for the able manner in which he had carried out the duties of his office. Financially, the Society had just turned a difficult corner, but it seemed as if conditions were now stabilised. Nevertheless, it would still be necessary for his successor as Treasurer to keep a watchful eye on the expenditure. The aim and object of the Society should be to increase its capital reserve, because it was only in this way that the subscription could be reduced. It was probably impossible to accumulate sufficient funds to warrant a general reduction in the subscription, but it was quite possible to build up a reserve fund which would enable the Council to lower the subscriptions of the younger Fellows, say for the first five years of their membership.

A Society renewed its youth by the infusion of new blood, and they must see that everything was done to help the infusion of

that new blood, without which the Society must inevitably die of old age.

Sir William Pope, in proposing the toast of "International Chemistry," said that they welcomed at their board many foreign friends. It was appropriate that the English Chemical Society was the first Society to drink the toast of "International Chemistry," because they were the oldest chemical society in the world, and during the last eighty-seven years they had seen grow up a large number of chemical societies all over the world; it was a privilege to invite their friends from the Continent to meet them at dinner.

They were honoured in having with them Professor Cohen, one of the greatest men in the chemical world, and one to whom they looked for many years to come to forward the interests of international chemistry, and to join the chemical societies of the world together in one great brotherhood for the development of chemical science. They had also with them distinguished gentlemen known to them by repute for many years, Professor Holmberg, from Stockholm, Professor Treadwell, from Switzerland, and Professor Wahl and Professor Komppa, from Helsingfors.

Professor Ernst Cohen in responding said :—

"Mr. President, Ladies, and Gentlemen, there exists a German adage : 'Steh' frisch auf, Tu's Maul auf, Hör' bald auf'; that is, in plain English, 'Rise briskly, open your mouth, be brief.' I generally follow this most practical advice but am sorry to say it will be impossible to do so to-night. I am invited, as you see on the menu, to respond to the toast of International Chemistry, on behalf of the Union Internationale and also the Nederlandsche Chemische Vereeniging. So I am standing before you Janus-faced. This implies that my toast cannot be as brief as it should be.

"Now there exists a very simple scheme for those who have to make a speech about old venerable Societies (as the Chemical Society is) when these are celebrating their anniversary. The man to whom we owe that scheme is Stephen Leacock. As you know, he is a Professor of Political Economy in MacGill University at Montreal, well known by his wit and his 'Discovery of England.' Leacock's model of such an anniversary speech would run as follows: 'Mr. Chairman, Ladies, and Gentlemen, If there is one thing I abominate more than another, it is turning out on a cold night like this to eat a huge dinner of twelve courses and know that I have to make a speech on top of it. Ladies and Gentlemen, I just feel stuffed. That is the plain truth of it. By the time we had finished that fish I could have gone home satisfied. Honestly I could. That's as much as I usually eat. And by the time I had finished the rest of the food I felt simply waterlogged, and so

I do still. More than that. The knowledge that I had to make a speech congratulating this Society of yours on its anniversary has haunted me all through the meal. I am not, in plain truth, the ready and brilliant speaker you take me for. That is a pure myth. If you could see the desperate home scene that goes on in my family when I am working up a speech, your mind would be at rest on that point. I'll go further, and be frank with you. How this Society has lived eighty-seven years I don't know. If all your dinners are like this, Heaven help you! I've only the vaguest idea of what this Society is, anyway, and what it does. I tried to get a Constitution this afternoon, but failed. . . .

"'It will be thirteen years before, please Heaven, you will celebrate the hundredth anniversary of this Society. I hope—I earnestly hope—that I shall be safely under the ground.'

"Now if you turn all this into the negative, it is exactly what I wanted to say. Not only on behalf of the International Union of Pure and Applied Chemistry, but also of my countrymen who deeply regret to be prevented from accepting your kind invitation to this dinner.

"It is long ago since Shakespeare put the question, 'What's in a name?' My reply is: There may be lots in a name! Look at the name of the International Union of Pure and Applied Chemistry I.U.P.A.C.—In this name you find condensed all the good wishes—and these are many—we bring to-night to the Chemical Society on behalf of the International Union:—

"I. means *Increase* of members and strength, in *Importance* and *Influence*.

"U. means *Unanimity*, wanted for the achievement of great deeds.

"P. not only means that we wish you in the future as good *Presidents* as the retiring one, but also that we hope that the Society will *Participate* more than ever in the work of the International Union.

"A. means the *Activity* of this Society and its *Achievements* in Chemistry, known all over the world, but equally its *Anniversary* we are celebrating to-day.

"C. means that we wish you *Concord: Concordia* res parvae crescunt! But C. also means the *Collaboration* with the Ladies in *Conventions*, such as we are enjoying at this very moment.

"I request my fellow-foreign guests to drink to the health and future of the Chemical Society."

Professor Dr. Bror A. L. Holmberg said:—

"Mr. President, Ladies and Gentlemen, on behalf of the Kemist-samfundet, Stockholm, I beg first to take the opportunity of

assuring the Chemical Society of our deepest gratitude for the invitation to this dinner and for the kindly way in which I have been treated here. As President of our Swedish Society I was very delighted to have this opportunity of coming here and thus of becoming acquainted with some of those distinguished chemists of whom I had read and heard so much. Then although it is true that chemistry is international, I nevertheless think that each country possesses some special characteristics, and though there is quantitatively a great difference between English and Swedish chemistry, it is easy to find many resemblances. I suppose this may be ascribed to that independent manner of thinking which the English as well as the Swedish people have in common, and which, especially here in England, has given, and is giving, birth to so many revolutionary and epoch-making theories and discoveries. I could say much more to you this evening, but considering the short time at my disposal I will limit myself to declaring my fullest agreement with the sentiments so ably expressed by Professor Cohen and on behalf of Swedish chemistry beg you to drink with me to the prosperity of British chemistry."

Prof. W. D. TREADWELL said that he had the great privilege and honour to convey to the Chemical Society heartiest greetings from the Société Suisse de Chimie.

He congratulated Prof. Cohen on his successful work as President of the International Union of Pure and Applied Chemistry and mentioned that the leading men in chemistry of his country were convinced that a continuous contact between the national chemical organisations would prove more and more to be a necessity. He expressed the hope that the International Union, which had for its object the internationalisation of chemistry in all its aspects, would continue to carry out its important and necessary work.

He recommended the exchange of talented students as a most important means for cultivating international relations, emphasising how important it was for young men to become acquainted with the chemistry of foreign countries, and mentioning that a knowledge of languages was a great help in this connection. Concluding, he expressed the hope that chemistry would prove one of the means towards the successful cultivation of happy international relations.

Professor WAHL said how greatly the members of the Chemical Societies in Finland, and both Professor Komppa and himself, had appreciated the invitation to be present at the Anniversary Meeting and at the Dinner. He stated that his colleague, Professor Komppa, had asked him to speak for both Societies, and referred to the debt his countrymen owed to the work of British chemists. He directed particular attention to the very high level at which

experimental work had ever stood and still stands in England. An outstanding feature of British chemistry is its excellent organisation.

He stated that the Society which he represented, the "Finska Kemistsamfundet," had about 200 members, and the "Soumalaisten Kemistien Seura," which Professor Komppa represented, 100; that most of these were employed in the pulp and paper industries of the country, and that about 80 per cent. of the whole export trade of Finland consisted of pulp and paper products.

In conclusion, Professor Wahl expressed thanks on behalf of Professor Komppa and himself for the hearty welcome they had received.

Professor F. G. DONNAN, submitting the toast of "The Guests," said that in addition to eminent foreign chemists from Finland, Holland, and Sweden, the Society had the pleasure of welcoming the Ministers for Switzerland and Finland. In the minds of most Englishmen, Switzerland was associated with Edelweiss, mountains, and winter sports, but he himself associated it with the beautiful cheeses which came from that country. Few Englishmen knew the lovely country of Finland, but he had once had the privilege of spending a holiday on an island in the Saima Sea, and could never forget the sunsets in that wonderful land of trees and lakes. Sir Frank Dicksee, no doubt, found himself, as an artist, amongst strange company, but he could assure him that chemists were not as bad as they were painted. He could assure Sir Frank that chemists were simply the honest brokers between the Almighty and His molecules. He would not say much about the atoms, since he, as a chemist, felt that the Devil had had something to do with the atom; or if it were not the Devil, then it was a syndicate of mathematical physicists, and that was pretty much the same thing. He hoped Sir Ernest Rutherford would forgive him for these apparently irreverent allusions.

They welcomed, last but not least, Sir Alfred Mond, whom they were glad to see safe home again from his adventures in the Near East. He understood, from references in the Press, that whilst all the fuss was going on, Sir Alfred was quietly growing bananas on his farm by the Sea of Galilee. He would have thought that oranges would do better, but no doubt it was a question of sulphate of ammonia.

Sir Alfred was a man of vision and imagination. The Universities were not able to produce chemists fast enough to satisfy his demands. At present there was a splendid breeze blowing through chemical industry, which was largely due to Sir Alfred Mond and his magnificent lieutenants, amongst whom he was specially glad to welcome

Lt.-Colonel Pollitt, the creator of Billingham. He would also like to refer to the extremely valuable work which Sir Alfred was doing in bringing about a closer and more intimate association between Labour and the Employer. The development of the chemical industry of Great Britain could be divided roughly into three periods. The first dated from about 1830, when the salt tax was removed, and was associated with the names of Muspratt, Allhusen, Gaskell, Deacon, Tennant and many others, who created the great heavy chemical industries of this country and ruined the amenities of Liverpool and the pleasant brooks of Lancashire. The second period dated from the eighteen-seventies, when Sir Alfred's very distinguished father, Dr. Ludwig Mond, created the great Solvay-Mond ammonia-soda works at Winnington in Cheshire. The third great period began with the magnificent developments at Billingham-on-Tees, where the firm of Brunner Mond and Company (and now Imperial Chemical Industries, Ltd.) had established the most marvellous and gigantic scientific industry that the British Empire had ever seen.

The Swiss Minister, in replying, said that it was always a source of satisfaction for anybody to have something in common with great men, even if such quality is of a negative nature. In this instance he could say, like Lord Chelmsford (if he was to take literally the words his Lordship had just used), that he knew nothing about chemistry. Nobody surely expected him to give a discourse on science in the presence of so many illustrious persons, for everybody knew that his activity lay in quite a different direction. The only contact he could possibly have with chemistry would be the occasional drafting of a diplomatic note or protest against the traffic of illicit drugs, or the use of poisonous gas in warfare.

In responding he would have to be content to express thanks on behalf of those whose chemical experience and observation were confined to the daily use of instruments originally the result of researches of great chemists; but as far as those guests were concerned, who were themselves pillars of art and science, he must leave it to such distinguished speakers as Sir Frank Dicksee and Sir Alfred Mond to take charge of them in a manner worthy of their merits.

Sir Frank Dicksee said that if he found himself in strange company, it was strange only in that it was seldom so pleasant. He had to reply not only for himself, but also for the ladies, and he somewhat regretted that one of the ladies present had not been invited to make one of the responses to the toast of the guests. Among other achievements he supposed that it was due to the

chemists that the silkworm had been outvied in its own product, and that an industry had been thus created which was more successful in this country than in any other. That industry might be the means of enabling them to pay their income tax; it might fill the empty ships to take this artificial silk to the distant parts of the world, and perhaps the shipping industry might revive as a consequence. So the fertile chemist had outdone the silkworm on its own ground, and had given employment to the people and wealth to the nation.

Sir Alfred Mond recalled that at the annual dinner in 1891 it was a matter of interest that a very distinguished statesman, who was also a considerable scientist, the late Marquis of Salisbury, made an interesting speech in which he suggested that there was no need for the world to go to Chili for its fertilisers, and that they could be got from the air. That prophecy had been fulfilled, and it was possible to obtain nitrogen from the air to-day. In the last few months he had been carrying out an investigation on the soil conditions in the Near East, and the need for nitrogen was apparent. The production of the world could be developed immensely by the co-operation of the chemist and the engineer, as had been combined so ably in this country in the works established at Billingham. Some of the problems that had haunted Malthus, the growth of the population and many of the speculations as to how the world was going to feed its people, would be temporarily solved by artificial chemical fertilisers. The future held no terror if they were able to produce cellulose, sugar, and other foods for themselves, and in another fifty years' time, and even sooner, synthetic food might be made, and with the action of soil nitration and soil bacteria it would be unnecessary to use the labours of the husbandman. He had seen these things on a small scale in the laboratory. He had seen synthetic vitamins, and soon it would be possible to synthesise all the food supplies we wanted, and we need be frightened no longer in war or peace that we would be starved out in isolation, but we would be able to support ourselves so long as we put up a few more factories. He was certain we could produce an infinite variety of flavours and more colours.

There were also a number of applications of the science of chemistry to the needs of the ladies. What would the colour of the lips of the female sex be to-day if it had not been for the perpetual thought of great scientists upon the consideration of what new shades of lip-stick they should have? There would not be any use for artificial silk if it could not be dyed. They had Mavis, a new shade, which would charm them in clothes that were coming to them in the near future. The monotonous colour of men's dress

would not keep going a single chemical factory. The ladies owed much to chemists, and chemists much more to them. If there were no women in the world, there would be no dye industry.

The chemical industry, through the Chemical Society, should be one of the civilising influences throughout the world.

Sir ERNEST RUTHERFORD, who spoke at the request of the President, said that in reading the history of chemistry he was impressed by the incredible industry of chemists throughout the ages, and one result of the enormous work of the chemists had been to produce the present civilisation. At the same time, he wondered whether the chemist would not have accomplished more if he had worked less and thought more. Chemists to-day were not trying sufficiently to understand the compounds they were making, and he thought that the chemists of the future would be superior to those of the past. He looked forward with the greatest hope that the slight line dividing physics and chemistry would disappear in the next decade and the two would become one great subject.

Ordinary Scientific Meeting, Thursday, March 29th, 1928, at 8 p.m., Professor J. F. THORPE, C.B.E., D.Sc., F.R.S., President, in the Chair.

The PRESIDENT referred to the loss sustained by the Society, through death, of the following Fellows:

	Elected.	Died.
Byron B. Goldsmith	May 16th, 1889.	Sept. 8th, 1927.
Mysore G. Srinivasa Rao	Feb. 17th, 1927.	Jan. 16th, 1928.

The PRESIDENT announced that:

1. The Council, at its meeting held that afternoon, had considered the advisability of altering the hour at which the Ordinary Scientific Meetings are held, and had decided that, as an experiment, the meetings arranged for May 3rd and 17th and June 7th and 21st, 1928, should be held at 5.30 p.m. instead of at 8 p.m.

2. The following Committees for 1928–1929 had been appointed by the Council:

Finance Committee: J. L. Baker, F. P. Dunn, C. A. Hill, G. T. Moody, J. C. Philip, R. H. Pickard, W. P. Wynne, and the Officers (Treasurer as Chairman), with the Assistant Secretary as Secretary.

House Committee: J. L. Baker, Sir Herbert Jackson, Sir William J. Pope, Sir Robert Robertson, Alexander Scott, J. M. Thomson, and the Officers, with the Assistant Secretary as Secretary.

Library Committee: T. A. Henry, J. R. Partington (Chairman),

Alexander Scott, N. V. Sidgwick, S. W. Smith, J. F. Spencer, and the Officers, together with representatives of contributing Societies, with the Librarian as Secretary.

Publication Committee: M. P. Applebey, H. Bassett, H. V. A. Briscoe, W. M. Cumming, H. W. Dudley, U. R. Evans, J. J. Fox, R. Whytlaw Gray, A. J. Greenaway, T. A. Henry, C. K. Ingold, J. Kenyon, H. King, G. T. Morgan, K. J. P. Orton, J. R. Partington, J. C. Philip, F. L. Pyman, E. K. Rideal, R. Robinson, N. V. Sidgwick (Chairman), J. L. Simonsen, S. Sugden, and the Officers, with the Editor as Secretary.

Research Fund Committee: A. J. Allmand, E. C. C. Baly, F. E. Francis, W. N. Haworth, C. K. Ingold, A. Lapworth, W. H. Mills, Sir Robert Robertson, N. V. Sidgwick, Sir James Walker, and the Officers, with the Assistant Secretary as Secretary.

3. Replicas of the Emil Fischer and the Carl Graebe Medals had been presented to the Society by Dr. Otto Rosenheim.

4. The following Address of Congratulation had been sealed and will be presented to the Sociedad Española de Fisica y Quimica on the occasion of the Silver Jubilee Celebrations of its foundation to be held in Madrid from April 9th to 15th, 1928. The Society will be represented at the functions by the President.

The Chemical Society
to the
Sociedad Española de Fisica y Quimica.

We, the President and Fellows of the Chemical Society, offer to you, the President and Members of the Sociedad Española de Fisica y Quimica, our sincere congratulations on the occasion of the Silver Jubilee of the foundation of your Society.

Twenty-five years have now elapsed since the first meeting of your Society was held, on the twenty-third day of March, 1903, under the Presidency of the distinguished Engineer, Don Jose Echegaray. During that period the published annals of the Sociedad Española de Fisica y Quimica have appeared year by year, and bear witness to the continuous development of scientific research in your country. Your land is the mother of the great Spanish family of nations, the leader and the *fons et origo* of that noble and dignified Spanish culture which is destined in the future, as in the past, to transmit to the nations of the world the great civilisation of Rome. With that ancient tradition you combine such an active and successful participation in the scientific research work of the modern world that with your resources an era of great happiness and prosperity lies before you—an era in which the

scientific work and influence of the Sociedad Española de Fisica y Quimica will be of the greatest importance. *Semper sit in flore!*

Signed on behalf of the Chemical Society,

L.S.

JOCELYN THORPE, *President.*
T. SLATER PRICE, *Treasurer.*
C. S. GIBSON, T. S. MOORE, } *Secretaries.*
F. G. DONNAN, *Foreign Secretary.*

Sealed in Council this Twenty-ninth day of March, One Thousand Nine Hundred and Twenty-eight.

The following were formally admitted Fellows of the Chemical Society: A. H. Dickins, T. Mitchell, W. E. Hugh, R. D. Satchell, R. Bowsher, and C. W. Holman.

Certificates were read for the first time in favour of:

Thomas Ballantyne Clerk, B.Sc., 111/112, Hatton Garden, E.C. 1.
Bertram Lionel Nicol, M.A., 40, Lawn Road, Exmouth.
John Poinier Rogers, 70, Warren Avenue, Nottingham.
Leonard Alfred Sayce, M.Sc., Ph.D., A.I.C., 5, Toward Terrace, Sunderland.

The following Certificate has been authorised by the Council for presentation to ballot under Bye-Law I (2) in favour of:

Peter Mar, M.A., M.Sc., 296, Ellen Street, Winnipeg, Canada.

The following papers were read:

"The chemistry of the three-carbon system. Part XVII. *α-cyclo*-Hexylideneacetone and -methylethyl ketone." By A. H. DICKINS, W. E. HUGH, and G. A. R. KON.

"The nitration of aromatic thiocyanates and selenocyanates." By F. CHALLENGER and A. T. PETERS.

"Effects induced by the phenyl group. Part I. The addition of polar reagents to styrene and the behaviour of the halogenated ethylbenzenes." By F. ASHWORTH and G. N. BURKHARDT.

"On selenium tetrafluoride." By E. B. R. PRIDEAUX and C. B. COX.

"The laws of aromatic substitution. Part VIII." By B. FLÜRSCHEIM and E. L. HOLMES.

ARRHENIUS MEMORIAL LECTURE.

The Arrhenius Memorial Lecture will be delivered by Sir James Walker, F.R.S., in the Theatre of the Royal Institution, Albemarle

Street, W. 1 (by the courtesy of the Managers), on Thursday, May 10th, 1928, at 5.30 p.m.

Admission will be by ticket only. Each Fellow of the Society is entitled to two tickets, application for which should be made as early as possible to the Assistant Secretary, Chemical Society, Burlington House, W. 1.

RESEARCH FUND COMMITTEE.

A meeting of the Research Fund Committee will be held in June next. Applications for Grants, to be made on forms which can be obtained from the Assistant Secretary, Chemical Society, Burlington House, W. 1, must be received on or before Friday, June 1st, 1928.

All persons who received grants in June, 1927, or in June of any previous year, whose accounts have not been declared closed by the Council, are reminded that reports must be returned by June 1st.

List of Papers, or Abstracts thereof, received between March 15th and March 29th, 1928. (This List does not include the titles of papers which have been read at an Ordinary Scientific Meeting, or which have appeared in the Journal.)

"The action of phosphorus pentachloride on homophthalic acid." By W. DAVIES and H. G. POOLE.

"Acid and salt effects in catalysed reactions. Part XIV. The influence of inert salts on the catalytic catenary for acetic acid–acetate mixtures." By H. M. DAWSON and A. KEY.

"The inhibition of esterification by pyridine." By K. C. BAILEY.

"The interaction of benzoyl chloride and diazomethane together with a discussion of the reactions of the diazenes." By W. BRADLEY and R. ROBINSON.

"Mobile hydrogen tautomerism analogous to the Wagner–Meerwein re-arrangement. Part II. The tautomerism of 1-(5)-hydroxy-2 : 2 : 3 : 3-tetramethyl*cyclo*pentan-5-(1)-one and its derivatives." By C. W. SHOPPEE.

"The nature of the alternating effect in carbon chains. Part XXVI. The mechanism of aromatic side-chain substitution." By C. K. INGOLD and E. ROTHSTEIN.

"The mechanism of the degradation of fatty acids by mould fungi. Part II." By P. D. COPPOCK, V. SUBRAMANIAM, and T. K. WALKER.

" The complex salts of β-methyltrimethylenediamine with bivalent platinum." By F. G. MANN.

" Mobile anion tautomerism. Part II. A complementary study of the mechanism of anionotropic change with special reference to the fate of the mobile anion." By H. BURTON.

" The occurrence of titanium tetrachloride in commercial disilicon hexachloride." By F. S. KIPPING and R. A. THOMPSON.

" Organic derivatives of silicon. Part XXXVI. Highly complex condensation products of diphenyl- and di-*p*-tolyl-silicanediol. Fission of the Si–Ph link." By F. S. KIPPING and A. G. MURRAY.

" Organic derivatives of silicon. Part XXXVII. The production of tetrabenzylsilicane oxide and other products by the action of sodium on dibenzylsilicon dichloride." By A. R. STEELE and F. S. KIPPING.

" Experiments on the synthesis of anthocyanins. Part IV. The constitution of *o*-benzoylphloroglucinaldehyde." By A. ROBERTSON, R. ROBINSON, and A. M. STRUTHERS.

" Experiments on the synthesis of anthocyanins. Part V. A synthesis of 3-β-glucosidylpelargonidin chloride, which is believed to be identical with callistephin chloride." By A. ROBERTSON and R. ROBINSON.

" The phosphorescent flame of sulphur." By H. J. EMELÉUS.

" The catalytic oxidation of nitro- and halogeno-derivatives of toluene by means of air." By E. B. MAXTED and A. N. DUNSBY.

CERTIFICATES OF CANDIDATES FOR ELECTION AT THE BALLOT TO BE HELD AT THE ORDINARY SCIENTIFIC MEETING ON THURSDAY, MAY 3rd, 1928.

BANERJI, RAMESH CHANDRA, Sainyer Gate, Jhansi, U.P. (India). Indian. Teaching. M.Sc. (Chemistry, First division), University of Allahabad. I have been teaching in the Government Inter. College, Jhansi, since 1922, and have been carrying on research work on the action of sunlight on some chemical changes, have submitted papers in some meetings of the Indian Science Congress, and in the *Zeitschrift für anorganische und allgemeine Chemie* in Germany. (*Signed by*) N. R. Dhar, K. P. Chatterjee, N. G. Chatterji.

BARRATT, ALFRED ERNEST, White House, Hawthorn Drive, Evington, Leicester. British. Brewer. I am interested in general and applied chemistry and would like to have the advantage of having the Journal. (*Signed by*) Chas. Geo. Matthews, S. F. Burford, F. C. Bullock.

BASU, SUDHIR CHANDRA, 21, Cromwell Road, South Kensington, London, S.W. 7. Hindu (Indian). Student of City and Guilds Engineering College. M.Sc. (Tech.), Calcutta University (Applied Chemistry). Worked in the

analytical department of the University College of Science, University of Calcutta. (*Signed by*) E. H. Farmer, M. Qudrati-Khuda, R. F. Hunter.

BRYANS, FRANK, 14, Church St., Pendlebury, Manchester. English. Chemist. B.Sc. (Tech.), M.Sc. (Tech.), Manchester. British Dyestuffs Corporation, 1921–22. 2½ Years' research experience, College of Technology, Manchester. "Electrolytic Reduction of Vat Dyes," *Chemistry and Industry*, Aug. 10, 1927. Present position: Chemist, British Dyestuffs Corp., Ltd. (*Signed by*) J. Kenner, F. A. Mason, John K. Wood.

BUCKLAND, HENRY SCOTT, Jesus College, Cambridge. British. Student. Being desirous to avail myself of the advantages of Fellowship of the Chemical Society. (*Signed by*) W. J. Pope, F. Gowland Hopkins, W. H. Mills.

CLARKE, BERTRAND STOCKDALE, Abbéville, 62, Algers Road, Loughton, Essex. British. Chief Pharmacist, Royal London Ophthalmic Hospital Dispensary, City Road, E.C. 1. Member of the Pharmaceutical Society (obtained at 17, Bloomsbury Square, W.C. 1). Lecturer in Chemistry and Pharmacy to Medical School, Royal London Ophthalmic Hospital, City Road, E.C. 1. Paper in preparation to be given on April 11, 1928, to Student Associates of the Pharmaceutical Society (Sheffield Branch). (*Signed by*) Ernest T. Neathercoat, W. A. Berry, V. H. Legg.

FRASER, JULIAN PAUL, c/o The Burmah Oil Co., Ltd., Syriam, Burma. British Subject. Chemist, Research Dept., The Burmah Oil Co. Inventor of process for extraction of aromatics and unsaturateds from mineral oils (Eng. Pat. 273,351), adopted by the Burmah Oil Co. Inventor of process for manufacturing lithopone without use of $ZnSO_4$ (Indian Pat. 1919). Process being worked in India. (*Signed by*) D. H. Peacock, M. Maung, M. G. Thein Kin.

GLASSPOOL, FREDERICK FRANK, Victoria College, Bath, Somerset. English. Senior Science Master, Victoria College, Bath. B.Sc. (Lond.). Senior Science Master (Chemistry, Physics, Botany), Victoria College, Bath, since 1924. Student at University College, Southampton, of Chemistry for London University B.Sc. Degree. (*Signed by*) D. R. Boyd, D. V. N. Hardy, H. H. Hatt, A. E. Clarence Smith.

GRIFFITHS, JOHN GAIUS ASHWELL, Gable Beach, Coppice Avenue, Great Shelford, Cambridge. English. Research Student. B.A., Cambridge, June 1927. A.I.C., October 1927. Research Student at Cambridge University Physical Chemical Laboratory since July 1927. (*Signed by*) T. M. Lowry, Eric K. Rideal, R. G. W. Norrish.

IVINS, DONALD VERNON, No. 208 (A.C.) Squadron, Royal Air Force, Egypt. British. R.A.F. officer and pilot. Past full-time student of Industrial Chemistry. (*Signed by*) Harry W. Webb, Ernest A. Rudge, W. J. Jones.

KELLETT, ALICE CORFIELD, Briarfield, 103, Claremont Road, Pendleton, Manchester. English. Student of University of London, taking the course for the London Trades' Diploma. B.Sc. (Chemistry Honours), at Manchester University, June 1927. Training to become a Chemistry Mistress in a High School. (*Signed by*) Arthur Lapworth, R. Robinson, Frederick Challenger, Arnold T. Peters.

LIANG, CHUAN-LING, 17, West Compound, Tsing Hua University, Peking, China. Chinese. Teacher. B.A., University of Wisconsin (1917). M.Sc., University of Chicago (1918). Teacher of Inorganic Chem. in Peking Academy (1919–22). Lecturer of Inorganic Chem. in Tsing Hua University (1922–27). (*Signed by*) John K. Wood, Arthur M. Morley, Thomas Kennedy Walker.

LUCAS, CHARLES EDWARD LESLIE, 27, Park Hill, Ealing, W. 5. British. Chemist. Associate of the Institute of Chemistry. Analytical Chemist

and Assistant to Works Manager, John Bell, Hills, & Lucas, Ltd., Manufacturing Chemists and Druggists, from 1922 to present date. (*Signed by*) H. B. Baker, James C. Philip, J. Stuart Hills.

MOON, SPENCER CLAUDE GASCOINE, "Medway," Amiens St., Gladesville, N.S.W., Australia. British Subject. Analytical Chemist. Studied chemistry for 3 years at Sydney Technical High School, passing Intermediate Exam. with "A's" in Chemistry and Physics. Five years pupil and later Assistant Analyst in laboratory of W. M. Hamlet, Sydney (late Government Analyst for 32 years, formerly a Fellow of Chemical Society). (*Signed by*) W. M. Doherty, C. E. Fawsitt, Thomas Iredale, Francis Lions.

MOORE, EDWARD WILLIAM JAMES, 307, Blackburn Road, Haslingden, Rossendale, Lancashire. English. Science Master. B.Sc., London. Hons. in Chemistry, 1910. A.I.C., 1918. Science Master, Haslingden Secondary School. (*Signed by*) E. C. C. Baly, T. P. Hilditch, C. Edward Sage.

MULLIN, CHARLES EARL, Clemson College, Box 157, Clemson College P.O., South Carolina, U.S.A. American. Professor of Textile Chemistry and Dyeing. M.Sc. (Natl.). Fellow Amer. Inst. of Chem. Fellow Textile Inst. (England). "Acetate Silk and its Dyes" (book, 1927); on staff of "Chemical Abstracts" about 8 years; Yearbook Amer. Pharmaceutical Assn., 1924, see p. 1; many papers upon "Wool" and related subjects since 1925 in *American Dyestuff Reporter*; see index of "Chemical Abstracts" for references to numerous papers in the literature since about 1924. Book on "Constitution of Wool" now in preparation. (*Signed by*) Albert Parsons Sachs, Austin M. Patterson, James Kendall.

OWEN, GLYN, Dalton Hall, Victoria Park, Manchester. British. University Assistant Lecturer. B.Sc., 1st Class Hons. Chem. (Wales). M.Sc. (Wales). Late Fellow of the University of Wales. J.C.S., 1923, **123**, 3392; 1924, **125**, 766 (joint publication with Prof. K. J. P. Orton, F.R.S.); 1926, **126**, 606 (joint publication with Prof. T. M. Lowry, F.R.S.). (*Signed by*) Kennedy Orton, H. B. Watson, F. G. Soper.

PATTON, GEORGE WILSON, 36, Arlington Street, Anlaby Road, Hull. British. Works Chemist. B.Sc., Leeds. Four years chemistry student at Leeds University. Now Chemical Assistant with Appleby Iron Co., Ltd., Scunthorpe, Lincs. Wish to join Society because of the privileges and value of the literature. (*Signed by*) Frederick William Richardson, Adolph Jaffé, H. M. Dawson, M. S. Burr.

PHILLIPS, RALPH OLIVER, 1A, North Gate, Regent's Park, London, N.W. 8 (business address, Forestal Central Laboratories, Harpenden, Herts.). American. Chief Chemist, Forestal Land, Timber, & Railways Co., Ltd. B.Sc., M.Sc., Tufts College, Massachusetts, U.S.A. Instructor, Analytical Chemistry, Tufts College, 1915–16; Chemist, Pittsburgh Plate Glass Co., Boston; Chemist, Picatinny Arsenal, N.J.; Chief Inspector smokeless powder and high explosives plant, Picatinny Arsenal, N.J.; Instructor in charge U.S. Army School for Inspectors of Powder and Explosives; Assistant Inspector of Powder and Explosives, U.S. Navy; Chemist and Development Engineer, The Barrett Co., New York; Chief Chemist, The Tannin Corporation, New York; Technical Consultant, The Forestal Land, Timber, & Railways Co., Ltd., London and Buenos Aires, The Natal Tanning Extract Co., Natal, S. Africa. Have written several articles which have appeared in *Journal of the American Leather Chemists' Association*, *Journal of Chemical and Metallurgical Engineering*, etc. (*Signed by*) Andrew Turnbull, M. C. Lamb, F. M. Rowe.

RAE, ALEC, The Trees, Thingwall Road, Wavertree, Liverpool. British.

Pharmacist. Pharmaceutical Society's Qualifying Examination, London, 1925. Pharmacist to the Liverpool Hospital for Consumption. I wish to receive the Chemical Society's Journals and have the use of the Library. (*Signed by*) Prosper H. Marsden, A. C. Abraham, H. Humphreys Jones.

RAMASWAMI, VAIDYANATHIER, 18, Luxemburg Gardens, Hammersmith, W. 6. British (Indian). Student. M.Sc. (Allahabad), 1st Class. Post-graduate research student at the Imperial College of Science, South Kensington. (*Signed by*) James C. Philip, H. J. T. Ellingham, M. K. Maitra, Jacob D. Cohen.

RAO, DEVANAHALLI KRISHNA, c/o The Commonwealth Trust, Ltd. (Late Basel Mission Industrials), Calicut, P.O., Malabar, S. India. Hindu. Chemist and Textile Colourist. B.Sc., Mysore University, Central College, Bangalore. Lecturer in Chemistry in the Government Collegiate High School, Bangalore (1921–22). Mysore Government Technical Scholar. Textile Colourist and Chemist to Messrs. The Commonwealth Trust, Ltd., Calicut, Malabar, South India, and in charge of their Dyeing and Bleaching and Soap Works and Laboratory since 1924. Senior member of the Society of Dyers and Colourists, London. (*Signed by*) V. G. Nair, A. Kesava Menon, V. M. Mascarenhas.

RICHARDSON, DONALD HENRY, 4, The Crossways, Onslow Village, Guildford. British. University Lecturer. Ph.D., M.Sc. (London). A.I.C. Senior Lecturer in Chemistry, Northern Polytechnic, London. Recognised teacher in the University of London. J.C.S., 1926, **129**, 522. (*Signed by*) H. J. S. King, T. J. Drakeley, G. J. Avey.

SESHADRI, TIRUVENKATA RAJENDRA, Chemical Department, University, Manchester. Indian. Research Student. M.A. (Chemistry) of the University of Madras, India. I have been engaged in chemical research for the past 5 years. Three of my papers have been published in the *Journal of the Indian Chemical Society* and one will soon appear in the *Journal of the Chemical Society*. A paper on "The Activity of the Double Bond in Coumarins and Related α-β-Unsaturated Carbonyl Compounds" will soon be published. (*Signed by*) John K. Wood, J. D. Fulton, W. Bradley, Z. Kitasato.

SPILLER, REGINALD HARVEY, Stonewall, Limpsfield, Surrey. British. Industrial Chemist (Imperial Chemical Industries, Ltd.). Associate Royal College of Science (A.R.C.S.). Associate Institute of Chemistry (A.I.C.). Diploma of Membership of the Imperial College (D.I.C.). Three years' research (1924–27) at the Royal College of Science, the results of which it is hoped will be published at once. (*Signed by*) H. B. Baker, Jocelyn Thorpe, James C. Philip, M. A. Whiteley.

TINGLE, ALFRED, Department of National Revenue, Ottawa, Canada. British. Chemist. B.Sc. (Aberdeen). B.Sc. (London). Ph.D. (Univ. of Pennsylvania). A variety of publications in *Journ. Soc. Chem. Ind.*, *Amer. Chem. Journ.*, *Journ. Amer. Chem. Soc.*, *Fuel. and Eng. Chem.*, *Science*, *Trans. Roy. Soc. Canada*, *Amer. Journ. Pharm.*, etc., from 1897 to date. *Trans.*, 1897, 1138–1148 (with F. R. Japp, F.R.S.). (*Signed by*) F. G. Wait, Alfred E. Macintyre, Frank T. Shutt.

WARREN, LEONARD ARTHUR, 16, Bourne Hill, Palmers' Green, London, N. 13. English. Research Student. B.Sc. (London) (not officially recognised till next year). I am engaged on my first year's research work (inorganic chemistry) at King's College, London, where I studied for the degree, and where I hold the position of Layton Research Student. (*Signed by*) Samuel Smiles, E. W. McClelland, W. B. Price.

WATERS, ROY BASIL, 124, Kingsland Road, Plaistow, E. 13. English.

Student. In order to keep abreast of contemporary work in pure chemistry. (*Signed by*) J. R. Partington, E. Roberts, E. E. Turner.

WEBB, WALTER WESTON, Fairmead Cottage, Spring Grove, Loughton, Essex. British born Subject. Chemist. Ph.D. (London). B.Sc. (London). A.I.C. Company Chemist, Cellactite Works, Ltd., Higham, Kent. Published work, in collaboration with Prof. A. J. Allmand, see "The Photolysis of Soda Hypochlorite Solutions," *Zeitsch. Phys. Chem.*, 131, 3/4, 189. (*Signed by*) A. J. Allmand, Samuel Smiles, E. W. McClelland, L. G. F. Dolley.

WHITELEY, WILLIAM LEONARD, 87, St. Mark's Road, Mitcham, Surrey. British. Schoolmaster. B.Sc. (London), 1st Class Hons. Chemistry. Teacher of Chemistry in Secondary Schools since 1915. (*Signed by*) P. C. Austin, R. T. Shepherd, Gerald Druce.

WILSON, RICHARD LLEWELYN, Gorphwysfa, Caersws, Montgomeryshire. British. Research Chemist. B.Sc. (Wales), Hons. in Chemistry, 1923. M.Sc. (Wales), 1925. Thesis on "The Vapour Pressures of Aqueous Solutions of Hydrofluoric Acid." Holding the position of Chief Research Chemist and Head of the Research Laboratory of The Phoenix Oil & Transport Co., Ltd., in Roumania since 1926. (*Signed by*) T. Campbell James, L. J. Hudleston, C. R. Bury, C. W. Davies.

WINTERTON, REGINALD JOSEPH, 30, Austin Street, King's Lynn, Norfolk. English. Student at East London College. In order to keep up with the latest work in chemistry. (*Signed by*) J. R. Partington, E. Roberts, E. E. Turner.

The following Certificates have been authorised by the Council for presentation to ballot under Bye-Law I (2):

CHI, YUOH FONG, Sterling Chemical Laboratory, Yale University, New Haven, Connecticut, U.S.A. Chinese. Graduate Student of the Department of Chemistry at Yale University. B.S. (Shanghai College, 1921). M.S. (University of Chicago, 1922). Prof. of Chemistry at National Wuchang University, Wuchang, China, in 1923–26. Lecture Assistant in the Department of Chemistry at University of Chicago in 1922–23. (*Signed by*) Richard H. F. Manske.

HARDY, FREDERICK, Windyridge, Curepe, Trinidad, B.W.I. English Professor of Chemistry and Soil Science. M.A. (Cambridge). Dip. Agric. Parts I and II (Cambridge). Soil papers in *J. Agric. Sci.*, XI, 1921, 1; XIII, 1923, 243, 340, 355; XV, 1925, 420, 434; XVI, 1926, 616. In *Soil Science*, XXIV, 1927, 71. In *J. Phys. Chem.*, XXX, 1926, 254. Chemical papers in *I.E.C.* XVII, 1925, 48, 1283. In *Bioch. J.*, XVIII, 1924, 283. In *J.S.C.I.*, XLIV, 1925, 305T. (*Signed by*) James P. Ogilvie.

HADDON, EDWARD CHARLES, Medical Research Laboratories, Entebbe, Uganda, Africa. English. Research Assistant. Matriculated, London 1920. Assistant and Student, Clinical Research Association, London 1908–15. Chemical Assistant, Military Service, R.A.M.C., France and Italy, 1915–18. Assistant, Clinical Research Assoc., 1919–20. Biochemical Research Assistant. Uganda Medical Service, 1920 to date. Two papers, "Apparatus for Continual Bacterial Growth" and "Observations on the Biochemistry of *B. abortus* and *melitensis*," *Roy. Soc. of Trop. Med. and Hyg.*, 1927. (*Signed by*) F. Mollwo Perkin, A. Prideaux Davson.

PROCEEDINGS

OF THE

CHEMICAL SOCIETY.

Ordinary Scientific Meeting, Thursday, May 3rd, 1928, at 5.30 p.m., Professor J. F. THORPE, C.B.E., D.Sc., F.R.S., President, in the Chair.

The PRESIDENT referred to the loss sustained by the Society, through death, on April 2nd, 1928, of Professor Theodore William Richards, who was elected an Honorary Fellow on February 6th, 1908.

The following were formally admitted Fellows of the Chemical Society: P. D. Coppock, J. D. Cohen, J. Lewkowitsch, A. G. White, and F. L. Gilbert.

Certificates were read for the first time in favour of:

Leslie Charles Baker, M.Sc., 14, Solna Road, Winchmore Hill, N. 21.
Charles Edwin Burnett, 51, Grasmere Crescent, Monton, Eccles.
Kanai Lal Dey, M.Sc.Tech., 21, Cromwell Road, S. Kensington, S.W. 7.
John Gordon Green, Downlands, Hove Park Road, Hove.
Ram Jiban Ghose, B.Sc., 42, Chaulpatty Road, Bhowanipore, Calcutta.
Edgar Henley Hecker, B.Sc., Oficinas, North Lagunas, Iquique, Chile.
William Deacon Jarvis, 6, Belle Vue Street, Healey, Batley.
Robert Haynes Jeffers, 87, Kyrle Road, Clapham Common, S.W. 11.
Albert William Kent, B.Sc., 104, Langdale Road, Thornton Heath.
Frederic Barry Kipping, B.A., Ph.D., 45, Fulbrooke Road, Cambridge.
Charles Bernard Maddocks, A.I.C., 102, Moor Street, Burton-on-Trent.
Spencer Mort, M.D., Ch.B., M.S., F.R.C.S., North Middlesex Hospital, Edmonton, N. 18.
Victor Harold Perkoff, c/o Curaçao Trading Co., Curaçao, Dutch West Indies.
Edwin Arnold Piper, 428, Aigburth Road, Aigburth, Liverpool.
Robert Anthony Robinson, M.Sc., c/o The Commonwealth Fund, 1 East 57th Street, New York.
Gerald Rex Shutt, M.A., 57, Westwood Avenue, Blackpool.
Laurence James Summerbell, B.Sc., 192, Holland Road, W. Kensington, W. 14.
Vernon Thorpe Tadman, A.I.C., Wissington Sugar Factory, Nr. Stoke Ferry, Norfolk.

Miss M. Carlton and Dr. J. N. Sugden were elected Scrutators, and a ballot for the election of Fellows was held. The following were subsequently declared elected as Fellows:

Ramesh Chandra Banerji, M.Sc.
Alfred Ernest Barratt.
Sudhir Chandra Basu, M.Sc.
Frank Bryans, M.Sc.
Henry Scott Buckland.
Yuoh Fong Chi, M.S.
Bertrand Stockdale Clarke.
Julian Paul Fraser.
Frederick Frank Glasspool, B.Sc.
John Gaius Ashwell Griffiths, B.A., A.I.C.
Edward Charles Haddon.
Frederick Hardy, M.A.
Donald Vernon Ivins.
Alice Corfield Kellett, B.Sc.
Chuan-Ling Liang, B.A., M.Sc.
Charles Edward Leslie Lucas, A.I.C.
Spencer Claude Gascoine Moon.
Edward William James Moore, B.Sc., A.I.C.
Charles Earl Mullin, M.Sc.
Glyn Owen, M.Sc.
George Wilson Patton, B.Sc.
Ralph Oliver Phillips, M.Sc.
Alec Rae.
Vaidyanathier Ramaswami, M.Sc.
Devanahalli Krishna Rao, B.Sc.
Donald Henry Richardson, Ph.D., M.Sc., A.I.C.
Tiruvenkata Rajendra Seshadri, M.A.
Reginald Harvey Spiller, A.R.C.S., A.I.C., D.I.C.
Alfred Tingle, B.Sc., Ph.D.
Leonard Arthur Warren, B.Sc.
Roy Basil Waters.
Walter Weston Webb, Ph.D., B.Sc., A.I.C.
William Leonard Whiteley, B.Sc.
Richard Llewelyn Wilson, M.Sc.
Reginald Joseph Winterton.

The following papers were read:

"The mechanism of the degradation of fatty acids by mould fungi. Part II." By P. D. Coppock, V. Subramaniam, and T. K. Walker.

"Experiments on the synthesis of anthocyanins. Part V. A synthesis of 3-β-glucosidylpelargonidin chloride, which is believed to be identical with callistephin chloride." By A. Robertson and R. Robinson.

"The phosphorescent flame of sulphur." By H. J. Emeléus.

"Studies of valency. Part IX. Molecular structure of thallium salts. (*a*) Thallium tri-iodide [with Mrs. R. R. Goldstein], (*b*) Alkyl derivatives [with F. L. Gilbert]." By A. J. Berry and T. M. Lowry.

Extra meeting held on Thursday, May 10th, 1928, at 5.30 p.m., in the theatre of the Royal Institution, Professor J. F. Thorpe, C.B.E., D.Sc., F.R.S., President, in the Chair.

Sir James Walker, LL.D., F.R.S., delivered the Arrhenius Memorial Lecture. A vote of thanks to the Lecturer, proposed by Professor F. G. Donnan, C.B.E., F.R.S., and seconded by Professor H. Brereton Baker, C.B.E., F.R.S., was carried with acclamation.

Ordinary Scientific Meeting, Thursday, May 17th, 1928, at 5.30 p.m., the President, Professor J. F. THORPE, C.B.E., D.Sc., F.R.S., in the Chair.

Reference was made to the loss sustained by the Society, through death on May 7th, 1928, of Walter Bezant Lowe, who was elected a Fellow on the 21st February, 1878.

The PRESIDENT announced:

1. That the following Address of Congratulation had been sealed and sent to the President and Members of the Mendeléeff Committee on the occasion of the Fifth Mendeléeff Congress at Kazan, June 15th to 21st, in honour of the centenary of Butleroff:

The Chemical Society
to the
President and Members of the
Mendeléeff Committee.

We, the President, Council, and Fellows of the Chemical Society, send to the President and Members of the Mendeléeff Committee our cordial greetings on the occasion of the Fifth Mendeléeff Congress at Kazan in honour of the memory of Professor A. M. Butleroff.

We recall the outstanding and fundamental investigations in the field of Organic Chemistry carried out by Butleroff, amongst which we would mention his important work on the tertiary alcohols, pinacoline, trimethylacetic acid, and more particularly on the unsaturated hydrocarbons.

We desire to associate ourselves with our Russian scientific colleagues and with chemists throughout the world in paying homage to the memory of Butleroff on the occasion of the Centenary of his birth, and we send cordial greetings, and best wishes for a most successful meeting at Kazan.

Signed on behalf of the Chemical Society,

LS

JOCELYN THORPE, *President.*
T. SLATER PRICE, *Treasurer.*
C. S. GIBSON, T. S. MOORE, } *Secretaries.*
F. G. DONNAN, *Foreign Secretary.*

Sealed in Council this Seventeenth Day of May, One Thousand Nine Hundred and Twenty-eight.

2. That a meeting of the Faraday Society would be held in the laboratory of Physical Chemistry, University of Cambridge, on

September 28th and 29th, 1928, when a general discussion would take place on the catalysis of homogeneous reactions, such as isomeric change, hydrolysis and esterification, association and dissociation, thermal decomposition, slow oxidation, etc. under the following headings:

1. Uncatalysed homogeneous reactions and negative catalysis.
2. Intermediate addition-compounds in homogeneous catalysis.
3. Neutral salt and activity effects in homogeneous catalysis.
4. Ionisation as factor in homogeneous catalysis.

Members and guests will be accommodated by the courtesy of the college authorities at Pembroke College during the two days of the meeting, and the attendance of Fellows of the Chemical Society will be heartily welcomed by the Council of the Faraday Society.

Miss A. C. Kellett was formally admitted a Fellow of the Chemical Society.

Certificates were read for the first time in favour of:

Margaret Ethel Birt, B.Sc., 20, Longton Avenue, Sydenham, S.E. 26.
Julian K. Dale, M.A., Ph.D., 2000 16th Street, N.W., Washington.
John Chaldecott Everett, Emmanuel College, Cambridge.
Percy James Fay, M.A., 8, Wilberforce Road, N. 4.
John Arthur Greene, 34, Dorset Square, N.W. 1.
Hedley Harrison, 4, Dorset Gardens, Hull.
Geoffrey Starkey Ward, 16, Haslemere Avenue, Bridlington.

The following Certificates have been authorised by the Council for presentation to ballot under Bye-Law I (2) in favour of:

Heinrich Hubert Maria Josef Houben, Dr.Phil., Hauptstrasse 29, Berlin.
Pokiarath K. Kurup, B.A., Calicut Soaps & Candles Co., Ltd., P.O. Box 52, Calicut.
Nicholas Francis Lovasz, 42, Engelwold Drive, Saxonwold, Johannesburg.

The following papers were read:

"The action of fluorine upon aqueous solutions of chromium and manganese salts." By F. Fichter and E. Brunner.

"Neocyanine." By F. M. Hamer.

"Syntheses of cyclic compounds. Part III. The reduction of some unsaturated cyano-esters with moist aluminium amalgam. A new synthesis of mono-substituted malonic acids and of ββ$\beta'\beta'$-tetramethyladipic acid. Further evidence for the multiplanar configuration of the *cyclo*heptane ring." By I. Vogel.

List of Papers, or abstracts thereof, received between March 29th and May 17th, 1928. (This List does not include the titles of papers which have been read at an Ordinary Scientific Meeting, or which have appeared in the Journal.)

"The heat of crystallisation of the normal long-chain hydrocarbons." By K. VAN BIBBER.

"Conditions of formation of rings attached to the *o*-, *m*-, and *p*-positions of the benzene nucleus. Part III." By A. F. TITLEY.

"A phase-rule investigation of cupric bromide in aqueous and hydrobromic acid solutions." By S. R. CARTER and N. J. L. MEGSON.

"Striated photographic records of explosion waves. Part II. An explanation of the striae." By C. CAMPBELL and A. C. FINCH.

"Electrometric titration curves of dibasic acids. Part I. Normal acids." By R. GANE and C. K. INGOLD.

"The lupin alkaloids. Part I." By G. R. CLEMO and G. C. LEITCH.

"The dilution and neutral salt errors of buffer mixtures." By C. MORTON.

"Dichloro-*o*-xylenes." By L. E. HINKEL, E. E. AYLING, and L. C. BEVAN.

"The isomeric α-aryl-2-aminocinnamic acids." By J. M. GULLAND and C. J. VIRDEN.

"The alkaline hydrolysis of esters in aqueous alcoholic solution. Part II. The interaction of phenoxides and aliphatic esters." By E. S. GYNGELL.

"The complete optical resolution of chloroiodomethanesulphonic acid." By J. READ and A. M. MCMATH.

"The action of bromine water on certain olefinic hydrocarbons and ethers." By J. READ and W. G. REID.

"The reaction between acetylene and sulphur at temperatures up to 650°." By J. B. PEEL and P. L. ROBINSON.

"The action of chlorine on jute fibre." By H. W. STRONG.

"Studies on the substituted quaternary azonium iodides. Part V. The molecular state of phenyldimethylazonium, phenylmethylethylazonium, phenyldiethylazonium, phenylmethylbenzylazonium, and phenylpropylbenzylazonium iodides in solution." By B. K. SINGH and M. R. SUD.

"The action of certain dibromotetracarboxylic esters on the sodium derivatives of ethyl malonate, ethyl ethanetetracarboxylate, and analogous substances." By J. J. LENNON and W. H. PERKIN.

"Experiments on the synthesis of brazilin and hæmatoxylin and their derivatives. Part III." By W. H. PERKIN, J. N. RÂY, and R. ROBINSON.

"Derivatives of 7 : 8 : 9 : 10-tetrahydro-αβ-naphthacarbazole and of 8 : 9 : 10 : 11-tetrahydro-α'β'-naphthacarbazole." By S. H. OAKESHOTT and S. G. P. PLANT.

"The influence of arsenic on the catalytic activity of platinum for the oxidation of sulphur dioxide." By E. B. MAXTED and A. N. DUNSBY.

"Optical activity and the polarity of substituent groups. Part IX. Menthyl esters of methoxynaphthoic and of diphenyl-2-carboxylic acids." By E. BRETSCHER, H. G. RULE, and J. SPENCE.

"An alternative formulation of the dilution law." By H. M. DAWSON.

"The nitration of *m*-fluorophenol." By H. H. HODGSON and J. NIXON.

"The condensation of hexahydrocarbazole and of tetrahydropentindole with *cyclo*pentanone cyanohydrin." By S. G. P. PLANT and D. M. L. RIPPON.

"2-Phenyl-1 : 3-diaminopropane and related compounds." By J. G. JACKSON and J. KENNER.

"The influence of constitution on the stability of racemates." By A. FINDLAY and A. N. CAMPBELL.

"Colloidal platinum. Part IV. The existence of hexahydroxyplatinic acid in colloidal platinum solutions." By S. W. PENNYCUICK.

"The influence of the intensity of illumination on the velocity of the photochemical union of bromine and hydrogen, and the determination of the mean life of a postulated catalyst." By F. BRIERS and D. L. CHAPMAN.

"A synthesis of pyrylium salts of anthocyanidin type. Part XV. The synthesis of cyanidin chloride by means of *o*-benzoylphloroglucinaldehyde." By A. ROBERTSON and R. ROBINSON.

"A synthesis of pyrylium salts of anthocyanidin type. Part XVI. The synthesis of pelargonidin chloride by means of *o*-benzoylphloroglucinaldehyde." By A. ROBERTSON, R. ROBINSON, and J. SUGIURA.

"A synthesis of pyrylium salts of anthocyanidin type. Part XVII. The synthesis of peonidin chloride by means of *o*-benzoylphloroglucinaldehyde." By S. MURAKAMI and R. ROBINSON.

"A synthesis of pyrylium salts of anthocyanidin type. Part XVIII. A synthesis of malvidin chloride." By W. BRADLEY and R. ROBINSON.

"Equilibrium in binary systems composed of cresols and amines." By N. A. PUSHIN and L. SLADOVITCH.

"The influence of intensive drying on the system nitrogen peroxide–nitric oxide–oxygen." By J. W. SMITH.

"The apparent hydration of ions. Part I. The densities and viscosities of saturated solutions of sodium and potassium chlorides in hydrochloric acid." By J. W. INGHAM.

"The synthesis of *meso*-alkyl and *meso*-aryl anthracene derivatives. Part IV." By E. DE B. BARNETT and J. L. WILTSHIRE.

"The electrokinetic potential between the solid and liquid states of a single substance." By F. FAIRBROTHER and F. WORMWELL.

"The interaction of cuprous chloride and the chromates of potassium in a solution of sodium chloride." By H. J. P. VENN and V. EDGE.

"Studies in colour and constitution. Part III. The influence of the methylthiol, methoxy-, and chlorine groups on the colours of the nitrobenzaldehydephenylhydrazones." By H. H. HODGSON and F. W. HANDLEY.

"Studies of valency. Part X. Electrometric titration of Vernon's α- and β-dimethyltelluronium bases." By F. L. GILBERT and T. M. LOWRY.

"Studies of valency. Part XI. Molecular conductivities and extinction-coefficients of derivatives of *cyclo*telluropentane." By F. L. GILBERT and T. M. LOWRY.

"The addition of halogens to unsaturated acids and esters. Part I. The addition of equimolecular mixtures of bromine and chlorine to cinnamic acid and its derivatives in non-hydroxylic solvents." By N. W. HANSON and T. C. JAMES.

"Cryoscopic irregularities with phenols." By G. M. RICHARDSON and P. W. ROBERTSON.

"The thermal decomposition of thiobenzanilide." By A. W. CHAPMAN.

"The action of substituted aromatic amines on camphoric anhydride-bromo- and iodo-camphoranilic acids and camphorobromo- and iodo-phenylimides." By M. SINGH, R. SINGH, and K. LAL.

"Steric hindrance in reactions of substituted quinoxalines." By G. M. BENNETT and G. H. WILLIS.

"*N* : *N*′-Diphenyl-*o*-phenylenediamine." By C. S. GIBSON and J. D. A. JOHNSON.

"Synthetical experiments on the aporphine alkaloids. Part III. A synthesis of corytuberine dimethyl ether." By J. M. GULLAND and R. D. HAWORTH.

"The relative reactivity of methylene groups in 1 : 3-diketones." By A. B. E. LOVETT and E. ROBERTS.

"Syntheses of cyclic compounds. Part IV. The catalytic decomposition of suberic acid and the preparation of suberone directly from mixtures of suberic and azelaic acids." By I. VOGEL.

"The adsorption of vapours on an amalgamated platinum surface." By J. W. SMITH.

"Resolution of racemic chlorobromoacetic acid." By H. J. BACKER and H. W. MOOK.

"Pseudo-ternary systems containing sulphur. Part III. Sulphur–sulphur monochloride." By D. L. HAMMICK and M. ZVEGINTZOV.

"The mechanism of tautomeric interchange and the effect of structure on mobility and equilibrium. Part III. The function of alkaline and acid catalysts in the mutarotation of some derivatives of tetramethyl glucose." By J. W. BAKER.

"On the nature of the deposit formed during the electrolysis of neutral and alkaline solutions with an antimony cathode." By J. GRANT.

"The molecular configurations of polynuclear aromatic compounds. Part VIII. 5 : 5-Dichlorodiphenyl-3 : 3′-dicarboxylic acid." By F. B. MCALISTER and J. KENNER.

CERTIFICATES OF CANDIDATES FOR ELECTION AT THE BALLOT TO BE HELD AT THE ORDINARY SCIENTIFIC MEETING ON THURSDAY, JUNE 21st, 1928.

BAKER, LESLIE CHARLES, 14, Solna Road, Winchmore Hill, N. 21. British. Assistant, Dept. of Biochemistry, University College, W.C. 1. B.Sc., M.Sc., London. Papers (with G. F. Marrian) *Biochem. J.*, 1927, **21**, 1005; (with G. F. Marrian, J. C. Drummond, and H. Woollard), *ibid.*, 1336; (with O. L. Brady, R. F. Goldstein, and S. Harris) *J.C.S.*, 1928, 529. (*Signed by*) J. C. Drummond, O. L. Brady, W. K. Slater.

BIRT, MARGARET ETHEL, 20, Longton Avenue, Sydenham, S.E. 26. British. Schoolmistress. B.Sc. London. Bedford College, London. Head of the Chemical Department (for last seven years), St. Paul's Girls' School, Hammersmith, W. 6. Hon. Sec. Association of Women Science Teachers. (*Signed by*) James F. Spencer, Ernest S. Hedges, Robert N. Kerr.

BURNETT, CHARLES EDWIN, 51, Grasmere Crescent, Monton, Eccles, Lancs. British. Chemist. Assoc. Manchester College of Technology. Full Technological Certificate, City and Guilds of London Institute, Oils and Fats. Painters' Oils, Colours, and Varnishes (First Class). For the last twenty years have studied pure and applied chemistry at Tottenham Polytechnic, Borough Polytechnic, Regent Street Polytechnic, and Manchester College of Technology. (*Signed by*) E. L. Rhead, Geo. Johnson, Charles Hy. Martin.

CLERK, THOMAS BALLANTYNE, 111/112, Hatton Garden, London, E.C. 1. British-born British subject. Chartered Patent Agent. B.Sc. of Glasgow

University. Studied pure and applied chemistry at Glasgow University and Royal Technical College, Glasgow. Chemistry and Metallurgy were taken as subjects in my B.Sc. examination. Have been a partner in the firm of Boult, Wade, & Tennant, Chartered Patent Agents, since March 1927, and have sole responsibility for my portion, largely chemical, of the firm's technical and legal business in connection with patent applications and patent litigation and advice to the firm's clients concerning their patents. (*Signed by*) Horatio Ballantyne, Robert Robertson, Dugald Clerk, J. N. Goldsmith, William H. Ballantyne.

DALE, JULIAN K., 2000, 16th Street, N.W., Washington D.C. U.S.A. American. Research Chemist. A.B., M.A., Ph.D., Princeton University. Member American Chemical Society. Publications in *J.A.C.S.* (*Signed by*) John Read, Geo. J. Robertson, J. Oldham.

DEY, KANAI LAL, 21, Cromwell Road, South Kensington, S.W. 7. Indian, Hindu. Student of City and Guilds Engineering College. M.Sc. (Tech.), Calcutta University (Applied Chemistry). Worked in the Analytical Department of the University College of Science. (*Signed by*) E. H. Farmer, M. Qudrati-Khuda, R. F. Hunter.

EVERETT, JOHN CHALDECOTT, The Brambles, Freshwater, Isle of Wight. English. Student. Honours Student in Chemistry (Cambridge). (*Signed by*) R. G. W. Norrish, F. G. Mann, R. E. D. Clark.

FAY, PERCY JAMES, 8, Wilberforce Road, London, N. 4. English. Research Chemist, Messrs. A. Sanderson & Sons, Ltd. M.A. (Cantab.), Int. B.Sc. (Lond.), late Exhibitioner of Christ's College, Cambridge. On leaving Cambridge, studied at Berlin University under Nernst (five semesters), and was afterwards an Assistant Chemist to Messrs. Mander Bros., Ltd., Wolverhampton. Have done a considerable amount of abstracting and reading through proof-sheets (paints and varnishes). Member Society of Chemical Industry and of Oil and Colour Chemists' Association. (*Signed by*) W. J. Pope, F. W. Dootson, A. J. Berry.

GHOSE, RAMJIBAN, 42, Chaulpatty Road, Bhowanipore, Calcutta, India. Indian, Hindu. Analytical and Technical Chemist. B.Sc., with "distinction" of the Calcutta University from the Presidency College, Calcutta. Eight years' experience as Analyst and Manufacturing Chemist in the Chemical Works of Messrs. Smith, Stanistreet & Co., Ltd., 18, Convent Road, Entally, Calcutta. (*Signed by*) H. Cooper, R. L. Datta, H. W. Thomas.

GREEN, JOHN GORDON, Downlands, Hove Park Road, Hove, Sussex. British. Analytical Chemist in Food Manufacturing. Five years' part-time student in Laboratory of Public Analyst and Manufacturing Chemist. Three years' practical experience in Food Manufacturer's Laboratory, and during greater part of this time have had full charge. (*Signed by*) William Jago, C. Edwd. Sage, F. W. F. Arnaud.

GREENE, JOHN ARTHUR, 34, Dorset Square, N.W. 1. British. Consultant Chemical Engineer to Bindphast Products, Ltd., Zambesin Mining Development Co., Ltd., late H.M. Petroleum Research Dept. (Admiralty). Editor, "Treatise on British Mineral Oils" (Griffin). Author, "Patent, Smokeless and Semi-Smokeless Fuels" (Pitman). (*Signed by*) Percy E. Spielmann, F. Mollwo Perkin, J. E. Hackford.

HARRISON, HEDLEY, 4, Dorset Gardens, Brunswick Avenue, Hull. British. Analyst for the past seven and a half years to Messrs. H. F. & Lee Smith, and also to the branches of Barkers & Lee Smith, Ltd., Hull. (*Signed by*) Geo. H. Appleyard, Harry Thompson, Thos. A. Nightscales.

HECKER, EDGAR HENLEY, Oficinas, North Lagunas, Iquique, Chile.

United States citizen. Chemist. B.Sc. (Lond.). (*Signed by*) F. G. Donnan, C. S. Gibson, Eric K. Rideal.

JARVIS, WILLIAM DEACON, 6, Belle Vue Street, Healey, Batley, Yorkshire. British. Power Station Chemist. Diploma Chemistry and Dyeing, Technical College, Bradford. (*Signed by*) F. W. Richardson, A. Jaffé, Leonard Seal.

JEFFERS, ROBERT HAYNES, 87, Kyrle Road, Clapham Common, London, S.W. 11. British. Botanist and Student of Chemistry. N.D. Hort., F.R.H.S. Diploma of the Wisley School of Horticulture, Student of Agricultural Chemistry at Wisley School of Horticulture, Edinburgh, and East of Scotland College of Agriculture, and Royal Botanic Garden, Edinburgh. Three months Organic Chemistry, Robert Gordon's Technical College, Aberdeen. (*Signed by*) Russell G. Thin, Francis V. Darbishire, H. J. Page.

KENT, ALBERT WILLIAM, 104, Langdale Road, Thornton Heath, Surrey. British. Schoolmaster. B.Sc. (2nd Hons. Chemistry), King's College, London. Hons. School Chemistry, King's College, London, 1922–24. Science Master, The Ingram School, Croydon, 1925–27, John Ruskin School, Croydon, 1927 to date. Paper on "Development of Theory of Chemical Effects of Electric Current," in preparation for M.Sc. (Hist. of Science). (*Signed by*) A. J. Allmand, Samuel Smiles, C. S. Salmon, L. T. M. Gray, H. W. Cremer.

KIPPING, FREDERIC BARRY, 45, Fulbrooke Rd., Cambridge. British. Demonstrator in Chemistry. B.A., Ph.D. (Cambridge). *J.C.S.*, 1924, **125**, 2396; 1926, 494, 1076; 1927, 528. (*Signed by*) W. J. Pope, H. McCombie, F. G. Mann.

MADDOCKS, CHARLES BERNARD, 102, Moor Street, Burton-on-Trent. British. Research Student. A.I.C. (*Signed by*) F. S. Kipping, E. B. R. Prideaux, B. D. Shaw.

MORT, SPENCER, Lt.-Colonel, North Middlesex Hospital, Edmonton, London, N. 18. British. Medical Superintendent and Surgical Director. M.B., Ch.B. (Hons.), M.D., M.S. (Glasgow), F.R.C.S., F.R.S. (Edin.). Trained Glasgow and West of Scotland Royal Tech. College, Glasgow (Student). Univ. Glasgow, Univ. Paris, Pasteur Institute, Paris (Research Fellow). Also Dresden and Institut du Radium, Univ. Paris (Research Fellow). (*Signed by*) A. M. Low, John Glaister, W. Lester, St. J. Alton.

NICOL, BERTRAM LIONEL, 40, Lawn Road, Exmouth, Devon. British. Schoolmaster. M.A. Cambridge. Senior Science Master, King's School, Rochester, since September 1924. (*Signed by*) W. G. Palmer, W. H. Mills, A. F. H. Ward, F. W. Dootson.

PERKOFF, VICTOR HAROLD, 37, Lea Bridge Rd., Clapton, E. 5 (present address, c/o Curaçao Trading Co., Curaçao, Dutch West Indies). British. Petroleum Chemist. Junior Chemist, W. J. Bush & Co., Hackney, E. 8, two years. Junior Works Chemist, English Oilfields, Ltd., Norfolk, two years. Chemist, J. E. Hackford, B.Sc., F.C.S., Research Laboratories, three years. Chemist, British Controlled Oilfields, Ltd., Curaçao, D.W.I. (*Signed by*) J. E. Hackford, Percy E. Spielmann, Otto L. Shaw.

PIPER, EDWIN ARNOLD, Moorland Villa, 428, Aigburth Road, Aigburth, Liverpool. British. Student of Analytical and Manufacturing Chemistry. Served as a Chemist in H.M. Forces throughout the entire period of War. Specially desire to receive the privileges accorded to Fellows of the Chemical Society. Specialising in Actinotherapy and Manufacturing Chemistry. (*Signed by*) Eric S. Brooks, Alex. W. McLaren, Francis Comer Savage.

ROBINSON, ROBERT ANTHONY, Rokeby, St. Bernards Road, Olton, Warwickshire (c/o The Commonwealth Fund, 1 East 57th Street, New York, U.S.A.). British. American Commonwealth Fellow. B.Sc. (Honours),

Birmingham, 1925. Qualified for M.Sc., Birmingham, 1926. Priestley Research Scholarship, Birmingham, 1925–26. D.S.I.R. Grant, 1925–27. American Commonwealth Fund Fellowship, 1927–29. *J.C.S.*, 1927, 267, 1906, 1912. (*Signed by*) W. N. Haworth, S. R. Carter, Wm. Wardlaw, E. Ashley Cooper.

ROGERS, JOHN POINIER, 70, Warren Avenue, Haydn Rd., Nottingham. British. Senior Assistant in Chemist and Pharmaceutical Laboratories. Senior Assistant for past eight years in laboratories of Messrs. Newball & Mason, Ltd., Manufacturing Chemists, Nottingham, and late student of the Nottingham University College. I desire to keep in touch with developments of Pure Chemistry and to use the publications in the Library for purposes of research. (*Signed by*) E. B. R. Prideaux, F. C. Laxton, F. Wilson Moulds.

SAYCE, LEONARD ALFRED, 5, Toward Terrace, Sunderland, Co. Durham. British. Lecturer in Chemistry, Armstrong College (University of Durham). M.Sc., Ph.D. (Dunelm). Associate of the Institute of Chemistry. Associate of the Institute of Physics. Formerly Chemist to Sunderland Gas Co.; Lecturer (part-time) in Chemistry, Physics, etc., at the Sunderland Technical College; Investigator under the Dept. of Scientific and Industrial Research. Publications: *Phil. Mag.*, 1925, **50**, 916; *J. Sci. Instr.*, 1925, **2**, 289; 1926, **3**, 20, 116; *J. Soc. Chem. Ind.*, 1921, **40**, R466; *Proc. Dur. Univ. Phil. Soc.*, 1924, **7**, 30; *Exptl. Wireless*, 1923, **1**, 70; 1924, **1**, 721; **2**, 9; 1926, **3**, 69, 144, 243, etc.; *J.C.S.*, 1925, **127**, 315; 1926, 957, 2623. (*Signed by*) H. V. A. Briscoe, G. R. Clemo, P. L. Robinson, R. D. Haworth.

SHUTT, GERALD REX, 57, Westwood Avenue, Blackpool, Lancashire. British. Chemistry Master, Blackpool Secondary School. M.A. (Cantab.), 2 Nat. Sci., Trip. I, 3 Nat. Sci., Trip. II. 1924–26, Chemistry Master, Tiffin Boys' School, Kingston-on-Thames. 1926 to date, Chemistry Master, Blackpool Boys' Secondary School. Since 1926 Teacher responsible for Chemical Trades Course, Blackpool Technical School. (*Signed by*) Charles T. Heycock, W. G. Palmer, W. H. Mills.

SUMMERBELL, LAURENCE JAMES, 192, Holland Rd., Kensington, W. 14. British. Science Master. B.Sc. (Lond.). Engaged on research work in Physical Chemistry for the past three years under Dr. J. Codrington Crocker at Chelsea Polytechnic with a view to taking the Ph.D. degree (Lond.). (*Signed by*) J. C. Crocker, Francis Arnall, Francis W. Hodges.

TADMAN, VERNON THORPE, Wissington Sugar Factory, nr. Stoke Ferry, Norfolk. British. Chemist. Associate of the Institute of Chemistry. Head Chemist, British Sugar Manufacturers, Ltd., Wissington Sugar Factory. (*Signed by*) H. Baines, G. Taylor, A. G. Crossley.

WARD, GEOFFREY STARKEY, 16, Haslemere Avenue, Bridlington, Yorkshire. English. Chemist and Druggist, M.P.S. Keenly interested in all new developments and discoveries. Student of Organic Chemistry. (*Signed by*) George A. Medley, H. England, H. C. Roberts.

The following Certificates have been authorised by the Council for presentation to ballot under Bye-Law I (2):

HOUBEN, HEINRICH HUBERT MARIA JOSEF, Berlin-Zehlendorf, Hauptstrasse 29. Deutschland. Ober-Regierungsrat und Mitglied der Biologischen Reichsanstalt Berlin-Dahlem, ausserordentlicher Professor der Chemie an der Universität Berlin. Magister artium liberalium und Dr.phil. (Bonn, 1898). Verfasser von etwa 100 Original-Mitteilungen in "Berichte der Deutschen chemischen Gesellschaft," *Journal für praktische Chemie, Chemiker-Zeitung,*

Arbeiten aus der Biologischen Reichs-Anstalt Berlin-Dahlem, etc., "Herausgeber der Methoden der organischen Chemie," 4 Bände (Leipzig, 2 Aufl., 1921–24, 3 Aufl. 1 u. 2 Bd., 1925–26), der "Fortschritte der Heilstoff-Chemie," 9 Bände, Bd. 1–4 erschienen (Berlin, 1926–28). (*Signed by*) Alex. McKenzie.

KURUP, POKIARATH KANNA, B.A., 2nd Lieutenant, Calicut (Malabar, India). British Indian. Managing Director, The Calicut Soaps and Candles Company, Ltd., Post Box 52, Calicut. B.A. (Madras University). Chemistry Lecturer. Asst. Supt. Govt. Soap Factory, Calicut. Three years' work on Oil Technology at the Ind. Inst. of Science, Bangalore. Joint author of a brochure on "Malabar Sardine Oil," with Dr. J. J. Sudborough and Dr. H. E. Watson as collaborators. 2nd Lieut. in His Majesty's Land Forces in India. (*Signed by*) J. L. Simonsen, V. M. Mascarenhas.

LOVASZ, NICHOLAS FRANCIS, 42, Engelwold Drive, Saxonwold, Johannesburg. British. Chemist. M.P.S. Chemist and Druggist, South Africa. Proprietor N. F. Lovasz & Co., Manufacturing and Analytical Chemists, Johannesburg. Manager, E. L. Ralling & Co., Pharmaceutical Chemists, Johannesburg. Manager, African Manufacturers & Importers, Ltd., Johannesburg. Manager, African Galenical & Research Laboratories, Johannesburg. Manager, African Mineral Products Co., Ltd., Johannesburg. Technical adviser to African Chemical Manufacturing Co., Ltd., Johannesburg. Now with Petersen, Ltd., Johannesburg. I am studying for a B.Sc. degree at University of South Africa. (*Signed by*) Max Rubin, Eugene Sachs.

PROCEEDINGS

OF THE

CHEMICAL SOCIETY.

Ordinary Scientific Meeting, Thursday, June 7th, 1928, at 5.30 p.m., Professor J. F. THORPE, C.B.E., D.Sc., F.R.S., President, in the Chair.

The PRESIDENT referred to the loss sustained by the Society, through death, of the following Fellows:

	Elected.	Died.
Walter Johnson Cooper	May 7th, 1891.	May 27th.
Frederick Mollwo Perkin	June 18th, 1891.	May 24th.

Angus F. H. Ward was formally admitted a Fellow of the Chemical Society.

Certificates were read for the first time in favour of:

William Robert Hardy Hurtley, B.Sc., Ph.D., 28, Chestnut Road, West Norwood, S.E. 27.

Kolar Ramakrishnaiyer Krishnaswami, B.A., 21, Cromwell Road, South Kensington, S.W. 7.

John William Smith, B.Sc., 70, Verdant Lane, S.E. 6.

The following papers were read:

"Studies of valency. Part X. Electrometric titration of Vernon's α- and β-dimethyltelluronium bases." By F. L. GILBERT and T. M. LOWRY.

"Studies of valency. Part XI. Molecular conductivities and extinction coefficients of derivatives of *cyclo*telluropentane." By F. L. GILBERT and T. M. LOWRY.

"The action of diazo-salts on aromatic sulphonamides. Part II. The mechanism of the reaction and the constitution of the diazosulphonamides." By A. KEY and P. K. DUTT.

Ordinary Scientific Meeting, Thursday, June 21st, 1928, at 5.30 p.m., Professor J. F. THORPE, C.B.E., D.Sc., F.R.S., President, in the Chair.

Reference was made to the loss sustained by the Society through

the death of Madyar Gopal Rau on May 21st, 1928, who was elected a Fellow on June 20th, 1918, and the PRESIDENT then called upon Professor J. R. Partington to make a statement.

Professor Partington said that the present month completed the twenty-fifth anniversary of Mr. Clifford's tenure of office as Librarian, and that it was unnecessary for him to explain to Fellows the many excellent qualities possessed by their Librarian. Many virtues went to the making of a good Librarian, and Mr. Clifford had them all. He was tactful, energetic and professionally efficient. The way in which he had organised the Library was worthy of great praise, especially when regard was paid to the fact that the books were distributed all over the building, for a large proportion of the books was in the basement, and they had now invaded the Council Room. That a book could be obtained so quickly from this scattered store was very creditable. In recent years increased demands had been made upon the services of the Librarian by reason of the availability of the Library to members of contributing Societies, but these demands had been met. He was sure that all Fellows who had had occasion to use the Library, either by personal visits or through the post, must have been assisted many times in obtaining information as to the literature of any particular subject in which they were interested. Professor Partington said he was sure all Fellows would associate themselves with him in expressing their appreciation of the services of their courteous and efficient Librarian.

The President conveyed to Mr. Clifford the thanks of the Council and Fellows for the able and efficient manner in which he had carried out the duties of his office during the past twenty-five years, and handed him a cheque from the Council and one from the Fellows, who had also given a clock.

In acknowledging these gifts, Mr. Clifford said he found it almost impossible to express in words his grateful thanks to the Council and Fellows for their generous recognition of his past services: his work as custodian of the Library had always been a pleasure, for there was joy in the chase after the ambiguous reference, and many a thrill in the pursuit of the elusive fact. Many of the inquiries received referred to matters of great variety and interest.

Mr. Clifford recalled that during the past twenty-five years the Library Committee had had but three Chairmen: Prof. Henry McLeod, who retired in 1904, Prof. J. Millar Thomson, who held the office for twenty years, and to whom he owed a great debt of gratitude for wise counsel and friendly advice, and Prof. Partington, who had been Chairman during the last four years. In acknowledging the friendly relations which had existed between Prof.

Partington and himself, Mr. Clifford thanked him most sincerely for the great amount of time and trouble he had so generously taken with regard to the presentation.

The PRESIDENT announced that

1. The following Address of Congratulation had been sealed in Council that afternoon, and would be presented by himself on the occasion of the Liebig-Wöhler Celebrations to be held at Darmstadt on July 7th, 1928 :—

The Chemical Society

to

the German Chemical Society, the Association of German Chemists, the Bunsen Society, and the Darmstadt Liebig House Committee

We, the President, Council, and Fellows of the Chemical Society, offer to our German Colleagues our sincerest congratulations on the auspicious occasion of the Liebig-Wöhler celebrations at Darmstadt and Giessen.

The great names of Liebig and Wöhler are known and revered throughout the civilised world as the founders of Organic Chemistry. The debt which humanity owes to Justus Liebig, the pioneer of agricultural chemistry and of the employment of artificial fertilisers in the cultivation of the soil, cannot be over-estimated. We in England owe to him the ideas which inspired the great work of Lawes and Gilbert at Rothamsted. The labours of the chemist in supplying artificial fertilisers to the farmers are of fundamental importance to-day, since without them prosperity would decline and famine soon face the vast and ever-growing population of the world.

We welcome with the liveliest satisfaction the preservation and restoration of the house in Darmstadt where Liebig was born. It will become one of the holy places of our science, which all chemists will visit.

Who can think of Liebig without recalling the name of his great collaborator, Wöhler? And who can think of Wöhler without recalling that it was he who first demonstrated the power of man to rival the operations of nature? Physiology, Biochemistry, Chemotherapy, and Medicine, as we understand these sciences to-day, became possible only after the work of Wöhler, who thus transcended Hippocrates and Galen and made Chemical Science the corner stone of the edifice of Life.

The co-operation of Liebig and Wöhler, who, beginning as rivals, soon became friends and collaborators, forms one of the happiest examples of good sense and just partnership known in science. In common with chemists throughout the world we of the Chemical

Society unite in wishing our German fellow scientists a very happy and successful meeting in Darmstadt.

Signed on behalf of the Chemical Society,

L.S.

JOCELYN THORPE,	*President.*
T. SLATER PRICE,	*Treasurer.*
C. S. GIBSON	*Secretaries.*
T. S. MOORE,	
F. G. DONNAN,	*Foreign Secretary.*

Sealed in Council this Twenty-first Day of June, One Thousand Nine Hundred and Twenty-eight.

2. The Council had decided that the Ordinary Scientific Meetings next Session should be held at 8.0 p.m.

J. G. A. Griffiths was formally admitted a Fellow of the Chemical Society.

Certificates were read for the first time in favour of:

Alfred Aaron Levi, M.Sc., 2, Ormonde Terrace, Regent's Park, N.W. 8.
Catherine Eleanor Mallen, M.A., The Red House, Beechwood Terrace, Sunderland.
Martha Elizabeth Murray, B.Sc., A.I.C., 90, Channel Street, Galashiels, Selkirkshire.

Dr. E. H. Farmer and Dr. E. E. Turner were elected Scrutators, and a ballot for the election of Fellows was held. The following were subsequently declared elected as Fellows:

Leslie Charles Baker, M.Sc.
Margaret Ethel Birt, B.Sc.
Charles Edwin Burnett.
Thomas Ballantyne Clerk, B.Sc.
Julian K. Dale, A.B., M.A., Ph.D.
Kanai Lal Dey, M.Sc.Tech.
John Chaldecott Everett.
Percy James Fay, M.A.
Ramjiban Ghose, B.Sc.
John Gordon Green.
John Arthur Greene.
Hedley Harrison.
Edgar Henley Hecker, B.Sc.
Heinrich Hubert Maria Josef Houben, Dr.Phil.
William Deacon Jarvis.
Robert Haynes Jeffers.
Albert William Kent, B.Sc.
Frederic Barry Kipping, B.A., Ph.D.
Pokiarath Kanna Kurup, B.A.
Nicholas Francis Lovasz.
Charles Bernard Maddocks, A.I.C.
Spencer Mort, M.D., M.S., F.R.C.S.
Bertram Lionel Nicol, M.A.
Victor Harold Perkoff.
Edwin Arnold Piper.
Robert Anthony Robinson, M.Sc.
John Poinier Rogers.
Leonard Alfred Sayce, M.Sc., Ph.D., A.I.C.
Gerald Rex Shutt, M.A.
Laurence James Summerbell, B.Sc.
Vernon Thorpe Tadman, A.I.C.
Geoffrey Starkey Ward.

The following papers were read :

"Acid and salt effects in catalysed reactions. Part XV. The catalytic activity of hydrochloric acid in the hydrolysis of ethyl acetate." By H. M. DAWSON and W. LOWSON.

"The chemistry of the three-carbon system. Part XVIII. Quantitative investigations on the $\alpha\beta$–$\beta\gamma$ change in unsaturated acids; observations on the reduction of sorbic acid and a new synthesis of pyroterebic acid." By A. A. GOLDBERG and R. P. LINSTEAD.

"The influence of structure on the solubilities of ethers. Part I. Aliphatic ethers." By G. M. BENNETT and W. G. PHILIP.

"The influence of structure on the solubilities of ethers. Part II. Some cyclic ethers." By G. M. BENNETT and W. G. PHILIP.

The Council has made the following Grants from the Research Fund :

	£	s.	d.
Aromatic substitution. J. W. Baker. (Leeds Univ.)	8	0	0
Production of fat from carbohydrates by fermentation. H. H. Barber. (Univ. Coll., Nottingham)	8	0	0
Aliphatic and cyclic sulphides (*contd.*). G. M. Bennett. (Sheffield Univ.)	8	0	0
Synthesis of some β-benziminazolylethylamines. B. C. Chatterjee. (Manchester Univ.)	12	0	0
$\alpha\beta$-Dicyano esters of aliphatic acids (*contd.*). P. K. Dutt. (Leeds Univ.)	8	0	0
Effect of substituents on the inhibition of organic reactions. G. M. Dyson. (Loughborough Coll.)	8	0	0
Simple unsaturated aliphatic ketones. E. N. Eccott. (Imperial Coll.)	8	0	0
Introduction of the triphenylmethyl group into phenols. D. V. N. Hardy. (Univ. Coll., Southampton)	8	0	0
The structure of the Grignard reagent. H. H. Hatt. (Univ. Coll., Southampton)	5	0	0
Experiments on the *iso*quinoline series. R. D. Haworth. (Armstrong Coll.)	8	0	0
Effect of polar and steric factors on the mobility of semicyclic triad systems. J. W. T. Jones. (Imperial Coll.)	8	0	0
Condensation of aldehydes with glycine anhydride (*contd.*). P. G. Marshall and W. P. Dickinson. (Leeds Univ. and Watford Grammar School)	5	0	0
Orientation of substituent groups in 5-hydroxyhydrindene. I. G. Nixon. (Cambridge Univ.)	8	0	0
Substituted adipic acids and their derivatives. (Miss) M. P. Oommen. (Imperial Coll.)	10	0	0
Effect of the so-called "strainless" rings on the carbon tetrahedral angle (*contd.*). K. A. N. Rao. (Imperial Coll.) ...	12	0	0
Constitution of Sparteine. R. Raper. (Armstrong Coll.) ...	8	0	0

Equilibrium mixtures of unsaturated methyl ketones (*contd.*). R. D. Satchell. (Imperial Coll.)	8	0	0
Synthesis of glucosides of pelargonidin. T. R. Seshadri. (Manchester Univ. and Univ. Coll., London)	20	0	0
The condensation product of fluorene with acetone. S. H. Tucker and J. W. Nicol. (Glasgow Univ.)	5	0	0
Synthesis of cyclic compounds (*contd.*). I. Vogel. (Imperial Coll.)	10	0	0
Mechanism of the oxidation of fatty acids by enzymes secreted by mould fungi (*contd.*). T. K. Walker. (Tech. Coll., Manchester)	8	0	0
Additive properties of conjugated compounds. F. L. Warren. (Imperial Coll.)	8	0	0
Spatial structure of *cyclo*paraffins. W. A. Wightman. (Leeds Univ.)	16	0	0
	£207	0	0

THE LIBRARY.

The Library will be closed for Stocktaking from Monday, August 6th, until Saturday, August 18th (inclusive). During the following four weeks (August 20th to September 15th), the Library will close daily at 5 p.m.

List of Papers, or Abstracts thereof, received between May 17th and June 21st, 1928. (This List does not include the titles of papers which have been read at an Ordinary Scientific Meeting, or which have appeared in the Journal.)

"The preparation and properties of pure phosphorus trioxide." By C. C. Miller.

"The rotatory dispersion of derivatives of tartaric acid. Part III. Diacetyltartaric acid and its esters." By P. C. Austin.

"The rotatory dispersion of derivatives of tartaric acid. Part IV. Dipropyl and dibutyl tartrates." By P. C. Austin.

"The decomposition of acetyl peroxide and the mechanism of Kolbe's electrosynthesis." By O. J. Walker.

"An electronic theory of catalytic oxidation and reduction." By A. W. Wellings.

"Syntheses in the diphenyl series." By L. E. Hinkel and D. H. Hey.

"The velocity of the acid hydrolysis of cotton cellulose by hydrochloric acid, alone and in presence of alkali chloride." By E. Hunter.

"Neodymium selenate." By J. A. N. Friend and A. A. Round.

"On the possibility of ring-chain valency tautomerism, and of a type of mobile-hydrogen tautomerism analogous to the Wagner–Meerwein re-arrangement. Part III. Orientation of some cyclic derivatives of phorone." By C. K. Ingold and C. W. Shoppee.

"The production of fat by a species of *penicillium* from carbohydrate and similar media. Part I. Glucose and sucrose." By H. H. Barber.

"Halogen derivatives of *o*- and *p*-azophenol." By L. Hunter and R. S. Barnes.

"The decomposition of bornyl benzene- and naphthalene-sulphonates by heat. The products of hydrolysis of bornyl and menthyl benzene- and naphthalene-sulphonates. The influence of solvents on the temperature of decomposition of these bornyl and menthyl sulphonates." By T. S. Patterson and I. M. McAlpine.

"The influence of solvents on the rotation of optically active compounds. Part XXV. Bornyl benzenesulphonate, bornyl naphthalene-α-sulphonate, and bornyl naphthalene-β-sulphonate in various solvents." By T. S. Patterson and I. M. McAlpine.

"The catalytic hydrogenation of different types of unsaturated compounds. Part III. The hydrogenation of conjugated systems." By S. V. Lebedev and A. O. Yakubchik.

"The action of nitrous acid on amino-compounds. Part II. Aliphatic amino-acids." By T. W. J. Taylor.

"A contribution to the chemistry and chemotherapy of aryl arsenoxides and dichloroarsines." By G. Newbery and M. A. Phillips.

"Studies of dynamic isomerism. Part XXVIII. Absorption spectra of the ketonic and enolic forms of an α-diketone." By T. M. Lowry and H. Moureu.

"Acid and salt effects in catalysed reactions. Part XVI. Catalytic effects in the iodination of mesityl oxide." By H. M. Dawson and A. Key.

"Styrylpyrylium salts. Part X. Anhydropyrylium bases and *spiro*pyrans derived from dibenzyl ketone." By R. Dickinson, I. M. Heilbron, and F. O'Brien.

"The hydrolysis of guanidine carbonate." By J. Bell.

"The Walden inversion." By H. N. K. Rördam.

"The preparation of some halogenoaminophenols. Part I. Mixed tetrahalogen derivatives of *o*-azophenol. Part II. Halogen

derivatives of *p*-hydroxyazobenzene." By L. HUNTER and R. S. BARNES.

"Studies in the pyrazole series. Part I. Anilopyrine and antipyrine and the relative migration of the hydroxyl group in anilopyrine alkylhydroxides." By P. K. DUTT.

"Derivatives of *ψ*-indoxyl*spirocyclo*hexane." By R. L. BETTS and S. G. P. PLANT.

"The action of disilicon hexachloride on ether." By F. S. KIPPING and R. A. THOMPSON.

"The constitution of magnesium acetate solutions. Part II. Evidence from vapour pressures." By E. A. GOODE, N. S. BAYLISS, and A. C. D. RIVETT.

"Note on the spectrum of the chemiluminescence accompanying the oxidation of ether, acetaldehyde, propaldehyde, and hexane." By H. J. EMELÉUS.

"*N*-Methyl derivatives of 2-phenylnaphthalene-1 : 3-diamine." By C. S. GIBSON, W. S. KENTISH, and J. L. SIMONSEN.

"10-Chloro-5 : 10-dihydrophenarsazine and its derivatives. Part VI. Compounds containing two nitrogen and two arsenic atoms in six- and five-ringed systems." By C. S. GIBSON and J. D. A. JOHNSON.

"By-products of the Gattermann aldehyde reaction." By F. BELL and T. A. HENRY.

"2 : 4 : 7-Trinitrofluorenone." By F. BELL.

"The photochemical decomposition of glyoxal vapour." By R. G. W. NORRISH and J. G. A. GRIFFITHS.

"Cobalt allylamines: a supposed co-ordination number of eight for cobalt." By W. R. BUCKNALL and W. WARDLAW.

"A resolution of benzoin." By I. V. HOPPER and F. J. WILSON.

"Synthetical experiments on the aporphine alkaloids. Part IV. A synthesis of morphothebaine dimethyl ether." By J. M. GULLAND and R. D. HAWORTH.

"Hydrolysis in solutions of potassium laurate as measured by extraction with benzene." By J. W. MCBAIN and M. EATON.

"Per-iodide equilibria in aqueous and salt solutions." By J. S. CARTER.

"The vacuum stability test: calculation of gas volume." By E. J. VAUGHAN.

"The action of magnesium phenyl bromide on methyl *o*-cyanobenzoate. 1 : 3-Diphenyldihydro*iso*indole." By D. R. BOYD and D. E. LADHAMS.

"The rotatory dispersion of certain isomeric butyl esters of *l*-mandelic acid." By C. E. Wood, A. E. Chrisman, and S. D. Nicholas.

"The nature of the alternating effect in carbon chains. Part XXVIII. The preparation and some properties of benzyl fluoride." By C. K. Ingold and E. H. Ingold.

"The nature of the alternating effect in carbon chains. Part XXIX. Further experiments bearing on the problem of the *ortho–para* ratio in aromatic substitution." By C. K. Ingold and C. C. N. Vass.

"Electrometric titration curves of dibasic acids. Part II. β-Substituted glutaric acids." By R. Gane and C. K. Ingold.

"Aminobenzthiazoles. Part X. The mobility of the 1-amino-3-methylbenzthiazole system." By R. F. Hunter and E. R. Styles.

"Nitration of 4-halogeno-2-hydroxy- and 2-halogeno-4-hydroxybenzaldehydes." By H. H. Hodgson and T. A. Jenkinson.

"The formation of 2-substituted benziminazoles." By M. A. Phillips.

"The quadrivalency of selenium. Part I. 4-Carboxydiphenyl- and *p*-carboxyphenyl methyl selenoxides." By W. R. Gaythwaite, J. Kenyon, and H. Phillips.

"The quadrivalency of selenium. Part II. The simple halogen derivatives and the dihydroxide of 4-acetamidodiphenyl selenide." By W. R. Gaythwaite, J. Kenyon, and H. Phillips.

"The quadrivalency of selenium. Part III. The instability of the compounds of quadrivalent selenium derived from phenyl methyl and phenyl ethyl selenides and phenyl- and *p*-tolyl-selenoglycollic acids." By O. K. Edwards, W. R. Gaythwaite, J. Kenyon, and H. Phillips.

"The solubility of potassium ferricyanide in water between 0° and 100°." By J. A. N. Friend and W. N. Smirles.

"The effects of the spatial position of substituent groups on acidic strength." By D. H. Hey.

"The conditions determining the thermodynamic stability of cyanohydrins of carbonyl compounds. Part I. Some effects of (*a*) substitution in aromatic aldehydes and (*b*) ring formation." By A. Lapworth and R. H. F. Manske.

ADDITIONS TO THE LIBRARY.

I. *Donations.*

BECK, CONRAD. The microscope. 2 vols. London 1923–24. pp. 144, 232. ill. (*Recd.* 11/6/28.) From Messrs. R. & J. Beck.

COLLOID SYMPOSIUM MONOGRAPH. Papers presented at the fifth National Symposium on Colloid Chemistry. New York 1928. pp. 394. ill. 27*s.* net. (Second copy.) (*Recd.* 15/6/28.) From Mr. E. Hatschek.

HOLMES, HARRY N. Laboratory manual of colloid chemistry. 2nd edition. New York 1928. pp. xviii + 228. ill. (Second copy.) (*Recd.* 15/6/28.) From Mr. E. Hatschek.

PROCEEDINGS

OF THE

CHEMICAL SOCIETY.

Extraordinary General Meeting, Thursday, October 18th, 1928, at 8 p.m. Professor J. F. THORPE, C.B.E., D.Sc., F.R.S., President, in the Chair.

The notice convening the meeting having been read, the PRESIDENT stated that in February, 1927, the Council had appointed a Committee to consider the provision of Committees, the election of Chairmen of Committees, the Chairmen of the Library and Publication Committees and also of the Bureau (if a Fellow) being *ex-officio* on the Council, and in what other ways the Bye-Laws should be altered. The Committee had met on several occasions, and its final report was received and adopted by the Council on June 21st, 1928.

Professor H. B. Baker then proposed that the additions to, and alterations of, the Bye-Laws, as detailed in the notice circulated to all Fellows resident in the United Kingdom, be adopted; the motion was seconded by Professor J. C. Philip.

Dr. R. H. Pickard asked for information as to what was involved in the proposed additions and alterations, and Professor C. S. Gibson made the following statement:

The present Bye-Laws contain no provision for the appointment of Committees or for framing Standing Orders. Under the new Bye-Law (to be numbered XIII) the Council seeks power (*a*) to appoint Committees; (*b*) in the case of the Library Committee, to invite each Society contributing to the upkeep of the Library to appoint a representative to serve on the Committee; (*c*) to co-operate with other similar bodies in carrying out schemes where combined action is necessary and to appoint Fellows as representatives to serve on any Joint Committee; (*d*) to delegate to such Joint Committee authority to incur expenditure in furtherance of such scheme, subject to such conditions as the Council may determine; (*e*) for the Bureau of Chemical Abstracts to be considered as a Joint Committee; and (*f*) for the Chairman of the Library Committee and of the Publication Committee and also the Chairman of

the Bureau (if a Fellow, or if not, a Fellow to be appointed by the Bureau) to be *ex-officio* Members of Council.

Under the new Bye-Law (to be numbered XIV) the Council seeks power to frame Standing Orders.

The proposed alterations give the Council power to make exceptions in special circumstances in dealing with the resignation and removal of Fellows; they provide that a retiring Vice-President shall not be eligible for re-election until after the lapse of one year, and that Ordinary Members of Council shall remain during their term of office in the category in which they are elected. Those Bye-Laws affected by the suggested new Bye-Laws are to be regularised, a verbal alteration in the Bye-Law dealing with the reading of certificates of candidates for election is to be made, and Bye-Law XX, which is no longer operative, is to be removed,

The motion was then put to the meeting and carried unanimously.

At the Ordinary Scientific Meeting which followed the PRESIDENT referred to the loss sustained by the Society, through death, of the following Fellows :

	Elected.	Died.
Gilbert J. Avey	Feb. 16th, 1922.	Aug. 8th.
Reginald A. Berry	Dec. 1st, 1898.	Oct. 12th.
Egerton C. Grey	Feb. 16th, 1922.	Aug. 10th.
William P. L. Hope	Dec. 4th, 1924.	Aug. 28th.
Henry R. Hoyles	April 4th, 1889.	May 7th.
Wilfred Irwin	Dec. 6th, 1883.	April 11th.
Alfred W. Mond	May 5th, 1927.	Sept. 12th.
Theophilus Pitt	Feb. 16th, 1882.	Aug. 30th.
Charles Platt	Feb. 16th, 1893.	June 14th.
Maurice S. Salamon	Dec. 3rd, 1908.	Sept. 19th.
Alfred Smetham	Dec. 16th, 1875.	Oct. 11th.
Charles W. Walker Tisdale	June 16th, 1898.	April 13th.

It was announced that :

1. The following presentations had been made to the Society :

By the President, medals struck in commemoration of the Liebig-Wöhler Celebrations.

By Dr. E. W. Maddison, the Pasteur Medal.

By Prof. H. E. Armstrong, photograph of group of chemists.

By Lady Tilden, various framed photographs.

2. The Annual Chemical Dinner would be held in the Connaught Rooms, Great Queen Street, W.C. 2, on Friday, November 9th, 1928, at 7 for 7.30 p.m. Tickets, price 12*s.* 6*d.* each, for lady or gentleman, including gratuities, but not wines, can be obtained from Mr. F. A. Greene, Honorary Secretary, Annual Chemical Dinner, 1928, Chemical Industry Club, 2, Whitehall Court, S.W. 1.

3. A circular letter had been received regarding "The New International Association for Testing Materials." This Association was formed at a Congress held in Amsterdam in 1927. In order to secure adequate British representation on the Association, a British Committee has been formed consisting of representatives appointed by a number of the most important British Institutions and Societies.

This Committee has appointed Dr. W. Rosenhain, F.R.S., as British representative on the Permanent Committee of the Association, of which body he has been elected as a Vice-President, and four International Committees have been appointed to deal with the four Sections into which the work of the Association is to be divided, namely, (*a*) Metals, (*b*) Inorganic non-metallic materials, (*c*) Organic materials, and (*d*) Methods of testing.

The annual membership subscription is 10*s.* for individuals, and not less than £1 for societies, firms, and other corporate bodies.

Further particulars of the Association, and forms of applications for membership, can be obtained from Mr. G. C. Lloyd, Honorary Secretary of the British Branch, 28, Victoria Street, S.W. 1.

The following were formally admitted Fellows of the Chemical Society: M. E. Birt, V. M. Thorn, B. Butterworth, W. L. Whiteley, A. Pollard, S. Murakami.

Certificates were read for the first time in favour of:

Arthur Donald Ainley, B.Sc., Highfield House, Dobcross, Oldham.
Nelson Alcock, Messrs. C. C. Wakefield & Co., Ltd., Spring Street, Sydney.
Rupchand Lilaram Alimchandani, M.Sc., Karnatak College, Dharwar, India.
Simon Amstell, 3, Ely Terrace, Mile End Road, E. 1.
William Rogie Angus, M.A., B.Sc., A.I.C., 35, Guildford Street, Russell Square, W.C. 1.
William Brookes, 473, Halliwell Road, Bolton.
Duncan Arthur Campbell, M.Sc.Tech., B.Sc., A.I.C., Roseleigh, Speldhurst, Tunbridge Wells.
Charles Ernest Chard, B.Sc., 53, Eleanor Road, Stratford, E. 15.
Joseph George Cockburn, B.Sc., 34, Cambridge Terrace, Gateshead-on-Tyne.
George Cecil Crummack, 130, Ash Road, Headingley, Leeds.
William Leslie Dixon, 14, Melrose Road, Merton Park, S.W. 19.
Shankar Magnath Godbole, Prof., M.Sc., College of Science, Nagpur, C.P., India.
John Grant Gordon, 23, Jennor House, Hunter Street, W.C. 1.
Frank Samuel Henry Head, B.Sc., 149, Fillebrook Road, Leytonstone, E. 11.
Rosalind Venetia Henley, 9, Oxford Square, W. 2.
Ralph Anderson Jackson, B.A., 46, St. James's Road, Carlisle.
Zenab Kamil, Bedford College, Regent's Park, N.W. 1.
Julian Maynard Leonard, 1, Lindfield Gardens, Hampstead, N.W. 3.
Charles Carr Marginson, B.Sc., The Homestead, Whitestakes, Preston.
Kottiazath Narayana Menon, M.Sc., 55, Parliament Hill, N.W. 3.
Albert Edward Oxford, M.Sc., Ph.D., 7, Talbotville Road, Broad Green, Liverpool.

Ronald Postell, B.A., 130, Saint John's Avenue, Bridlington.
Alfred Russell, B.Sc., The Queen's University, Belfast.
Sidney John Saint, B.Sc., A.I.C., Government Laboratory, Barbados.
Rupert Henry Saunders, Littlecot, Windsor Road, Slough.
Harry Selikman, B.Sc., 46, Harpur Avenue, Benoni, Transvaal.
Kantilal Maganlal Sheth, M.Sc., Shree Shakti Alkali Works, Dhrangadhra, Kathiawad, India.
Henry George Simpson, B.Sc., 21, Truro Road, Wood Green, N. 22.
William Solomon, B.Sc., 14, Finsen Road, S.E. 5.
Cyril Gordon Sumner, M.Sc., 53, St. Thomas' Road, Chorley.
Ramsimha Thakur, M.Sc., Mandla Fort, Mandla, C.P., India.
Arthur Ernest Vaughan, jun., Quebec Lodge, Regent Road, Birkdale, Southport.
George Reginald Webster, 8, Marlborough Road, Bearwood, Birmingham.
Margaret Katharine White, M.Sc., Northern Polytechnic, N. 7.
William Dudley Williams, B.Sc., F.I.C., Cia Industrial y Comercial de Petroleo, Canadon Rosales, Comodoro Rivadavia, Argentine.

The following Certificates have been authorised by the Council for presentation to ballot under Bye-Law I (2):

Alexander Lipworth, 23, Kerk Street, Johannesburg.
Walter William Saw, B.Sc., c/o Vacuum Oil Co., Ltd., Perth, W. Australia.

The following papers were read:

"Studies of dynamic isomerism. Part XXVIII. Absorption spectra of the ketonic and enolic forms of an α-diketone." By T. M. Lowry, H. Mourеu, and C. A. H. MacConkey.

"Explosions in closed cylinders. Part I. Methane-air explosions in a long cylinder. Part II. The effect of length of the cylinder." By W. A. Kirkby and R. V. Wheeler.

"Explosions in closed cylinders. Part III. The manner of movement of flame." By O. C. de C. Ellis and R. V. Wheeler.

"Pentanitroaniline." By B. Flürscheim and E. L. Holmes.

LECTURE.

The first Liversidge Lecture, entitled "Physical Chemistry in the Service of Biology," will be delivered by Professor F. G. Donnan, C.B.E., D.Sc., F.R.S., in the Lecture Hall of the Institution of Mechanical Engineers, Storey's Gate, S.W. 1, on Thursday, November 29th, 1928, at 5.30 p.m. Admission Free. Tickets will not be issued.

ANNUAL REPORTS.

The price of the Annual Reports for 1928, Vol. XXV, will be 5*s.* 6*d.* to those Fellows who apply by December 31st, 1928.

Application should be made to the Assistant Secretary, and must be accompanied by a remittance.

FARADAY LECTURES.

The Faraday Lectures which have been delivered before the Society since the Lectureship was founded in 1868 are now published in volume form. The volume contains twelve Lectures, with portraits of the Lecturers, an obituary notice of Faraday, and a short history of the foundation of the Lectureship. The volume can be obtained from the Assistant Secretary, and the price to Fellows is 5*s*. 6*d*. post free.

ABSTRACTS "A" FOR 1929.

(*Printed on one side of the paper only*)

Abstracts "A" (Pure Chemistry) for 1929, printed on one side of the paper only, will be issued at the reduced price of £1 to those Fellows who make application to the Assistant Secretary by December 31st, 1928. A remittance for £1 must accompany each application, and Fellows should state, when ordering, if they wish to receive the Abstracts gummed or ungummed.

THE CHEMICAL SOCIETY AS ITS OWN PUBLISHER.

The Council has decided that as from December 31st, 1928, the Society shall act as its own Publisher. All communications regarding the publications should, as from that date, be addressed to the Assistant Secretary, The Chemical Society, Burlington House, Piccadilly, W.1.

PUBLICATIONS OF OTHER SOCIETIES.

Fellows of the Chemical Society who are not members of the Society of Chemical Industry, the American Chemical Society, or the Dutch Chemical Society, may procure the publications of these Societies for 1929 at the following prices:

SOCIETY OF CHEMICAL INDUSTRY

(*a*) Abstracts in Applied Chemistry (exclusive of Index). £1 10*s*. post free
(*b*) Annual Reports of the Progress of Applied Chemistry for 1928 . . . . . 10*s*. „
(*c*) Abstracts in Applied Chemistry (printed on one side of the paper only) . . . . . £2 „

Application should be made direct to the Secretary, Society of Chemical Industry, 46 and 47 Finsbury Square, E.C. 2, and should reach him by 31st December, 1928. Fellows resident abroad should apply by return of mail.

AMERICAN CHEMICAL SOCIETY

(*a*) Journal of the American Chemical Society . . $7·25 post free
(*b*) Chemical Abstracts . . . . . $7·75 ,,
(*c*) Industrial and Engineering Chemistry . . . $7·25 ,,
Price for all three Journals : $18·00 post free.
Price for any two Journals : $13·50 post free.
(*d*) Chemical Reviews . . . . . $4·50 ,,
Application should be made direct to the Secretary, American Chemical Society, Mills Building, Washington, D.C., U.S.A., and should reach him by December 31st, 1928.
(*e*) Journal of Physical Chemistry . . . . $8·00 post free
Application should be made to the Journal of Physical Chemistry, Ithaca, N.Y., U.S.A.

NEDERLANDSCHE CHEMISCHE VEREENIGING

(*a*) Chemisch Weekblad . . . . . Fl. 10·00 post free
(*b*) Recueil des travaux chimiques des Pays Bas . . Fl. 11·50 ,,
Application to be made to Dr. A. D. Donk, Nederlandsche Chemische Vereeniging, Verspronckweg, 100, Haarlem, Holland.

NOTE.—*A remittance, made payable to the Society concerned, must accompany each application.*

RESEARCH FUND.

A meeting of the Research Fund Committee will be held in December next. Application for Grants, to be made on forms obtainable from the Assistant Secretary, must be received on or before Saturday, December 1st, 1928. Applications from Fellows will receive prior consideration.

All persons who received Grants in December, 1927, or in December of any previous year, whose accounts have not been closed by the Council, are reminded that Reports must be returned by December 1st.

List of Papers, or Abstracts thereof, received between June 21st and October 18th, 1928. (This List does not include the titles of papers which have been read at an Ordinary Scientific Meeting, or which have appeared in the Journal.)

"Mineral trees: their formation and significance." By M. COPISAROW.

"The influence of solvents on the rotation of optically active compounds. Part XXVI. The optical activity of malic acid in the presence of sodium molybdate." By T. S. PATTERSON and C. BUCHANAN.

" Colour and constitution. Part IV. The absorption spectra of nitrophenylhydrazones in alcohol and alcoholic potash." By H. H. Hodgson and K. E. Cooper.

" Determination of the pressure and density of saturated ammonium bromide vapour." By A. Smits and R. Purcell.

" Some complex salt studies. Part I. The preparation and properties of some selenitopentamminecobalt salts." By H. L. Riley.

" The iodometric estimation of iron." By E. C. Grey.

" The nature of hexagonal chromium." By A. J. Bradley and H. Muller.

" 1 : 3-Dichlorobenzene-4 : 6-disulphonic acid and its salts." By E. B. Kidson.

" Selective solvent action. Part VII. Solubilities in mixed solvents." By N. Gregg-Wilson and R. Wright.

" Note on the formulation of dissymmetric diphenyl derivatives." By R. J. W. Le Fèvre.

" The heat of adsorption of oxygen on charcoal. Part III." By D. McKie.

" The condensation of fluorene with acetone." By P. Maitland and S. H. Tucker.

" The acylation of diazomethane : The effects of variations in the conditions on the extent of formation of chloroacetophenone from benzoyl chloride." By W. Bradley and G. Schwarzenbach.

" The ionisation of aromatic nitro-compounds in liquid ammonia. Part II." By W. E. Garner and H. F. Gilbe.

" The interaction of acids and neutral salts with stannic oxide and its relation to electrical charge." By B. N. Ghosh.

" The chemistry of the 1 : 3-dicarbonyl compounds. Part I. The mechanism of the cyanoacetamide and cyanoacetic ester condensations." By J. C. Bardhan.

" Studies in the composition of coal. The rational analysis of coal." By W. Francis and R. V. Wheeler.

" The condensation of chloral with 2 : 6-dichloroquinol." By F. D. Chattaway and F. Calvet.

" Some substitution products of azobenzene." By J. Burns, H. McCombie, and H. A. Scarborough.

" Acid and salt effects in catalysed reactions. Part XVII. The variation of the catalytic activity of an acid with its concentration and the determination of ionisation constants." By H. M. Dawson, G. V. Hall, and A. Key.

" On active nitrogen. Part V. (Amended.) The decay of the nitrogen afterglow." By E. J. B. Willey.

"The addition of halogens to unsaturated acids and esters. Part II. The addition of 'bromine chloride' to phenylpropiolic acid and the interaction between the αβ-dihalogenocinnamic acids and the halogens." By N. W. HANSON and T. C. JAMES.

"The condensation of chloral with anisic acid and with *p*-nitroanisole." By F. D. CHATTAWAY and F. CALVET.

"The condensation of pyrocatechol with dichloroacetic acid. 2 : 2′-Dihydroxydiphenoxyacetic acid." By H. A. A. AITKEN.

"The partial substitution of polyhydric alcohols. Part VII. The unreliability of structure in disubstituted glycerols." By A. FAIRBOURNE and G. W. COWDREY.

"The interaction of ethyl acetoacetate with distyryl ketones. Part IV. Selective addition to unsymmetrical chlorodistyryl ketones." By I. M. HEILBRON and R. HILL.

"The production of thiophen by the interaction of acetylene and carbon disulphide." By H. V. A. BRISCOE, J. B. PEEL, and P. L. ROBINSON.

"The reactions of hydrogen chloride with the dioxides of selenium and tellurium between 0° and 170°, with special reference to alleged addition compounds." By T. W. PARKER and P. L. ROBINSON.

"Note on paper by Hartley and Barrett on 'The determination of the density of liquids.'" By J. GRINDLEY.

"On active nitrogen. Part VI. The formation of iron nitride in the iron–nitrogen arc." By E. J. B. WILLEY.

"Determination of the pressure and density of moist saturated ammonium chloride vapour." By A. SMITS and W. DE LANGE.

"The inhibition of chemical reactions. Part II. The mechanism of the inhibition of esterification by alkaline substances. Part III. A suggestion with regard to antioxygenic action." By K. C. BAILEY.

"An *X*-ray examination of the potassium salts of the monobasic fatty acids." By S. H. PIPER.

"Adsorption of vapour on a quartz- and glass wall." By A. SMITS.

"The synthesis of four amino-3-hydroxy-1 : 4-benz*iso*oxazines. By G. NEWBERY and M. A. PHILLIPS.

"Heterocyclic compounds containing arsenic. Part II. Derivatives of 1 : 4-benz*iso*oxazine." By G. NEWBERY, M. A. PHILLIPS, and R. W. E. STICKINGS.

"Heterocyclic compounds containing arsenic. Part III. Some derivatives of 4-amino-3-hydroxyphenylarsinic acid." By I. E. BALABAN.

"Molecular structure in solution. Part IV. The densities, vis-

cosities, and electrical conductivities of aqueous sol utions of cobalt chloride and hydrochloric acid at different temperatures." By O. R. HOWELL.

"The nitration of *o*-bromoacetanilide." By C. S. GIBSON and J. D. A. JOHNSON.

"The dependence of rotatory power on chemical constitution. Part XXXIII. The resolution of *dl*-*m*-carboxyphenyl ethyl sulphoxide and of *dl*-*m*-carboxyphenylethylsulphine-*p*-toluenesulphonylimine." By J. HOLLOWAY, J. KENYON, and H. PHILLIPS.

"The decay of the nitrogen after-glow." By W. C. BRAY and T. R. HOGNESS.

"The reaction between the dioxides of sodium and tellurium." By T. W. PARKER and P. L. ROBINSON.

"Researches on indoles. Part I. 5 : 6-Dimethoxy-2-methylindole." By F. LIONS.

"Some trimethoxyquinoline derivatives." By F. LIONS.

"Glucosides. Part I. The formation of glucosides from 3 : 4 : 6-triacetyl glucose-1 : 2-anhydride." By W. J. HICKINBOTTOM.

"An attempt to prepare selenium oxyfluoride by distillation of hydrogen fluoride with selenium dioxide." By J. O. MILLOTT and E. B. R. PRIDEAUX.

"The acetylation of diethylene oxide." By Miss M. MACLEOD.

"The reduction of nitro-compounds by aromatic ketols. Part II. Some *o*-, *m*-, and *p*-azoxy-compounds." By H. B. NISBET.

"The effect of the spatial position of substituent groups on acidic strength." By B. FLÜRSCHEIM.

"Nitroarylsulphuric acids and their reduction products." By G. N. BURKHARDT and H. WOOD.

"The infra-red emission spectra of flames in nitrous oxide." By C. R. BAILEY and KUN-HOU LIH.

"*ortho*-Sulphinobenzoic acid." By W. B. PRICE and S. SMILES.

"Carbon sulphidoselenide." By H. V. A. BRISCOE, J. B. PEEL, and P. L. ROBINSON.

"The chlorination of anilides. Part V. The significance of velocity measurements in relation to the problem of benzene substitution (*continued*)." By A. E. BRADFIELD and B. JONES.

"A gas circulating pump." By G. BARR.

"A study in the 2-substituted derivatives of *p*-cresol." By M. COPISAROW.

"Surface oxidation of aluminium, tungsten, and molybdenum." By L. C. BANNISTER.

"The alkaloids of some Indian aconites. Part II. Pseudaconitine." By T. M. SHARP.

"Synthetical experiments in the *iso*flavone group. Part III. A synthesis of genistein." By W. BAKER and R. ROBINSON.

"Acid and salt effects in catalysed reactions. Part XVIII. The dynamics of auto-catalysed ester hydrolysis." By H. M. DAWSON and W. LOWSON.

"Synthesis of oxydehydrocorydaline." By J. B. KOEPFLI and W. H. PERKIN.

"On the constitution of laurotetanine." By G. BARGER and R. SILBERSCHMIDT.

"Heterocyclic compounds containing arsenic. Part IV. Some urea derivatives of arylarsinic acids." By R. W. E. STICKINGS.

"Stability of ferrous sulphate solutions and their use in standardising permanganate." By J. A. N. FRIEND and E. G. K. PRITCHETT.

PROCEEDINGS

OF THE

CHEMICAL SOCIETY.

Ordinary Scientific Meeting, Thursday, November 1st, 1928, at 8.0 p.m., Professor J. F. THORPE, C.B.E., D.Sc., F.R.S., President, in the Chair.

The PRESIDENT referred to the loss sustained by the Society, through death, on October 13th, of Edward John Wall, who was elected a Fellow on June 19th, 1919.

The following were formally admitted Fellows of the Chemical Society: Robert H. Jeffers, Wilson Baker, A. Robertson, William Bleloch, R. J. Winterton, T. R. Seshadri.

Certificates were read for the first time in favour of:

Owen Stanley Brettle, Red Hall Road, Lower Gornal, Dudley.
Albert James Butterworth, B.Sc., 44, Hind Street, E. 14.
Aaron Cohen, B.Sc., 114, Langdale Mansions, E. 1.
Arthur William Martin Dickins, 2, Rotherwick Court, Golders Green, N.W. 4.
Allan Domleo, M.Sc., Charnwood, Southfield Park, Harrow.
Constance Mary Groocock, B.Sc., 25, St. Peter's Mount, Bramley, Leeds.
Gerald Uern Hopton, B.A., 25, Museum Road, Oxford.
Joe Arthur Jessop, B.Sc., 2, Bradley Terrace, Shadwell Lane, Moortown, Leeds.
Jason Thomas William Mann, A.R.C.S., The Homestead, Burcharbro Road, Abbey Wood, S.E. 2.
Albert Edward Martin, B.Sc., 47, Mildmay Grove, N. 1.
Nellie Patterson, 23, Ferndene Road, Herne Hill, S.E. 24.
Albert Fred Tipler, B.Sc., 13B, Harley Street, Bow, E. 3.
Tekumalla Venkajee, B.A., Rajahmundry, Madras Presidency, India.
William Francis Kenrick Wynne-Jones, The University, Reading.

The following papers were read:

"Surface oxidation of aluminium, tungsten, and molybdenum." By L. C. BANNISTER.

"Synthetical experiments in the *iso*flavone group. Part III. A synthesis of genistein." By W. BAKER and R. ROBINSON.

"Anthoxanthins. Part X. A synthesis of gossypetin and of quercetagetin." By W. BAKER, R. NODZU, and R. ROBINSON.

"The electrical conductivities of some uni-univalent salts in benzonitrile. Evidence for the incomplete dissociation of strong electrolytes and the applicability of the law of mass action to their dissociation." By A. R. MARTIN.

Ordinary Scientific Meeting, Thursday, November 15th, 1928, at 8 p.m., Professor J. F. THORPE, C.B.E., D.Sc., F.R.S., President, in the Chair.

The PRESIDENT referred to the loss sustained by the Society, through death, of the following Fellows:

	Elected.	Died.
Douglas J. P. Berridge	June 15th, 1893.	Nov. 11th.
Albert Clarke	Dec. 2nd, 1920.	Oct. 7th.
John W. Patterson	Dec. 5th, 1912.	Oct. 3rd.
Walter Tate	Dec. 18th, 1884.	Sept. 8th.
Edmund White	Feb. 17th, 1927.	Nov. 3rd.
John Wild	May 7th, 1891.	Sept. 28th.

It was announced that

1. Professor Samuel Smiles had presented a medal struck in commemoration of Moissan and his isolation of fluorine.

2. Professor C. S. Gibson, Mr. A. J. Greenaway, Dr. J. T. Hewitt, and Professor G. T. Morgan, together with Dr. T. Slater Price (Treasurer), had been appointed by the Council to represent the Society on the Bureau of Chemical Abstracts for the year 1928—1929, and that Professor A. J. Allmand, Professor J. Kendall, and Professor F. G. Donnan would represent the Society on the Editorial Board of the *Journal of Physical Chemistry* for the year 1929, together with Dr. E. K. Rideal, appointed by the Faraday Society.

3. The Railway Companies had granted special facilities by which Fellows and others attending the Anniversary meetings in Leeds on March 21st, 1929, will be enabled to travel by rail to Leeds from any part of the country at the rate of an ordinary single fare and one-third for the double journey, provided that not less than 200 avail themselves of the cheap tickets. Tickets will be available from March 20th to 22nd. Those desiring to avail themselves of this privilege must apply to the Assistant Secretary for a voucher, which must be surrendered to the Booking Office when purchasing the ticket.

Full particulars of the arrangements for the meetings will be announced later.

4. The Council had decided that a copy of the portrait of Liebig (the gift to the Society of Mrs. Alec Tweedie) should be presented by the Council and Fellows to the German Chemical Society. Any Fellow desiring to subscribe to the cost of the copy should send his contribution to the Treasurer.

5. The Centenary of the birth of Paul Schutzenberger will be celebrated in Paris towards the end of 1929. A Fund has been formed in Paris by the Centenary Committee, and the income from this Fund will be devoted to the award of grants and prizes for

scientific industrial research. Fellows desiring to subscribe to the Fund are invited to send their contribution M. le Professeur G. Urbain, Secrétaire Général, 1, Rue Victor Cousin (Sorbonne), Paris.

The following were formally admitted Fellows of the Chemical Society :—H. C. Gull and P. L. Robinson.

Certificates were read for the first time in favour of :

Charles Mills Cawley, B.Sc., A.R.C.S., 69, Richmond Road, Gillingham.
Sydney William Challinor, B.Sc., The Rosary, Myvod Road, Wednesbury.
Frederick Hurn Constable, M.A., D.Sc., Ph.D., St. John's College, Cambridge.
Ranchhodji Dajibhai Desai, B.A., M.Sc., 21, Cromwell Road, South Kensington, S.W. 7.
Amarendra Nath Dey, M.Sc., 153, Chamberlayne Road, Kensal Rise, N.W. 10.
Edward Thomas Mervyn Garlick, M.Inst.C.E., Block Chambers, Little Malop Street, Geelong, Victoria, Australia.
Frederick Hemming, 15, Nightingale Road, Southsea.
Henry Malcolm Forrest Hughes, 37, High Street, Smethwick.
Elfed Thomas Jones, B.Sc., 149, Fillebrook Road, Leytonstone.
Abbas Mousa Mousa Mandour, 24, Hill Top Mount, Harehills, Leeds.
Leslie George Brett Parsons, B.Sc., A.R.C.S., 73, Lynton Avenue, Ealing.
Millicent Mary Theodosia Plant, B.Sc., 55, Willenhall Road, Bilston, Staffs.
Sydney Walter Slaughter, B.Sc., 90, Westcliff Park Drive, Westcliff.
Ethel Gertrude Teece, B.Sc., Grafton, Moxley Road, Darlaston, Staffs.
Harry Augustus Thomas, B.Sc., 42, Cole Valley Road, Hall Green, Birmingham.
Clarence Sydney Woolvin, B.Sc., 35, Wyley Road, Radford, Coventry.
Winifred Mary Wright, M.A., Ph.D., Shaftesbury House, Shaftesbury Road, Cambridge.

The following Certificates have been authorised by the Council for presentation to ballot under Bye-Law I (2) :

Shankar Lal Jindal, Prof., M.Sc., 101/118, Talag Mahal, Cawnpore.
Benjamin Stuart Paschall, M.D., 1014, American Bank Building, Seattle, Washington, U.S.A.
Taizo Yamashita, Prof., Asamacho 4, Mukden, China.

The following papers were read :

" The densities of butyric acid–water mixtures." By J. Grindley and C. R. Bury.

" Studies of valency. Part XII. Isomeric derivatives of diethyl telluride." By F. L. Gilbert and T. M. Lowry.

" Studies of valency. Part XIII. Further experiments on the molecular structure and configuration of the quadrivalent derivatives of tellurium." By T. M. Lowry and F. L. Gilbert.

" The effect of intensive drying on certain physical properties of benzene." By H. V. A. Briscoe, J. B. Peel, and P. L. Robinson.

" The passivity of metals. Part II. The breakdown of the protective film and the origin of corrosion currents." By U. R. Evans.

List of Papers, or Abstracts thereof, received between October 18th and November 15th, 1928. (This List does not include the titles of papers which have been read at an Ordinary Scientific Meeting, or which have appeared in the Journal.)

"The structure of the normal monosaccharides. Part V. Lyxose." By E. L. HIRST and J. A. B. SMITH.

"Heterocyclic compounds of arsenic. Part V. Benziminazole arsinic acids." By M. A. PHILLIPS.

"The Budde effect in bromine." By E. MATTHEWS.

"Studies in the composition of coal. The active decomposition-point of coal." By R. HOLROYD and R. V. WHEELER.

"Note on the rate of photochemical combination of chlorine and hydrogen in glass capillary tubes." By D. L. CHAPMAN and P. P. GRIGG.

"Derivatives of diphenyl-2-carboxylic acid." By F. BELL.

"Crystallography of the aliphatic dicarboxylic acids." By W. A. CASPARI.

"Influence of poles and polar linkings on the course pursued by elimination reactions. Part II. Mechanism of exhaustive methylation" (*continued*). By C. K. INGOLD and C. C. N. VASS.

"Influence of poles and polar linkings on the course pursued by elimination reactions. Part III. A decomposition of dialkyl-sulphones." By G. W. FENTON and C. K. INGOLD.

"An attempt to prepare *iso*indole." By G. W. FENTON and C. K. INGOLD.

"Hydroxy-derivatives of thioxanthone dioxide." By W. B. PRICE and S. SMILES.

"The infra-red emission spectra of burning sulphur compounds." By C. R. BAILEY and KUN-HOU LIH.

"The oxidation of dipinene." By L. H. BRIGGS and W. F. SHORT.

"Experiments on the degradation of quaternary ammonium salts." By T. S. STEVENS, E. M. CREIGHTON, and A. B. GORDON.

"The migration of radicals in quaternary ammonium salts. Part I." By T. S. STEVENS and M. MACNICOL.

"Researches in the menthone series. Part VI. The crystallisation of menthylamines with optically active acids." By J. READ, C. C. STEELE, and P. G. CARTER.

"Esters of phosphoric acid. Part I. Cetyl and cholesteryl phosphates." By R. H. A. PLIMMER and W. J. N. BURCH.

"Esters of phosphoric acid. Part II. The action of ethyl meta-

phosphate on alcohols." By R. H. A. PLIMMER and W. J. N. BURCH.

"Esters of phosphoric acid. Part III. The action of ethyl metaphosphate on ammonia and some amino-compounds." By R. H. A. PLIMMER and W. J. N. BURCH.

"Esters of phosphoric acid. Part IV. Hydrolysis by acid and alkali." By R. H. A. PLIMMER and W. J. N. BURCH.

"Esters of phosphoric acid. Part V. Phosphoric esters of chlorethyl alcohol and glycol." By R. H. A. PLIMMER and W. J. N. BURCH.

"Replacement of halogen in *ortho*-bromobenzoic acid." By W. R. H. HURTLEY.

"The solubility of sodium ferrocyanide in water between 0° and 100°." By J. A. N. FRIEND and J. E. TOWNLEY.

"The interaction of piperidine with nitro- and halogeno-nitro-derivatives of xanthone and diphenylene oxide." By R. J. W. LE FÈVRE.

"On the electrical behaviour of surfaces of corroding iron." By A. L. MCAULAY and S. H. BASTOW.

"Stereoisomerism of disulphides and related substances. Part III. Some pairs of aromatic disulphoxides." By E. V. BELL and G. M. BENNETT.

"The thermal decomposition of ammonia with reference particularly to the Baly–Duncan effect." By W. A. STRINGFELLOW.

"Researches on residual affinity and co-ordination. Part XXXI. Molybdyl bis-β-diketones." By G. T. MORGAN and R. A. S. CASTELL.

"The mechanism of corrosion." By U. R. EVANS.

"Carbocyanine dyes with substituents attached to the three-carbon chain." By F. M. HAMER.

"The condensation of dichloroacetaldehyde with phenols." By F. D. CHATTAWAY and A. A. MORRIS.

"Colloidal platinum. Part V. The coagulation by electrolytes in acid solution." By S. W. PENNYCUICK.

"Colloidal platinum. Part VI. The nature of the surface of colloidal platinum particles, and the action of bases thereat." By S. W. PENNYCUICK.

"Colloidal platinum. Part VII. The coagulation by electrolytes in basic solution." By S. W. PENNYCUICK.

"Studies in ketol-lactol tautomerism. Part I. Ring-chain tautomerism in α-carboxy-ββ-dimethyl-γ-acetylbutyric acid and a synthesis of ββ-dimethyl-γ-acetylbutyric acid." By M. QUDRAT-I-KUDA.

"The action of aromatic acid chlorides on vinyldiacetoneamine." By J. GRAYMORE.

"The rotation dispersion and circular dichroism of caryophyllene nitrosite." By S. MITCHELL.

"Anthoxanthins. Part VIII. A synthesis of morin and of 5 : 7 : 2′ : 4′-tetrahydroxyflavone." By R. ROBINSON and K. VENKATARAMAN.

"Anthoxanthins. Part IX. Syringetin." By T. HEAP and R. ROBINSON.

"Properties of conjugated compounds. Part VI. The dibromination products of cyclic butadienes." By E. H. FARMER and W. D. SCOTT.

"The catalytic hydrogenation of different types of unsaturated compounds. Part IV. The hydrogenation of conjugated systems. Piperinic acid." By S. V. LEBEDEV and A. O. YAKUBCHIK.

"Synthetical experiments in the chromone group. Part I. A new synthesis of 7 : 8-dihydroxy-2-methylchromone and 7 : 8-dihydroxyflavone." By K. VENKATARAMAN.

"The action of acids upon diazoaminobenzene." By J. C. EARL.

"Aminobenzthiazoles. Part XI. The effect of substituents on the Hugershoff transformation in derivatives of thiocarbanilide." By G. M. DYSON, R. F. HUNTER, and C. SOYKA.

"Observations on the chlorination products of ββ′-dichlorodiethyl sulphide. Part II." By J. W. C. PHILLIPS, J. S. H. DAVIES, and S. A. MUMFORD.

"Reduction products of the hydroxyanthraquinones. Part VIII." By R. W. HARDACRE and A. G. PERKIN.

"Interactions of selenium oxychloride and phenols." By G. T. MORGAN and F. H. BURSTALL.

FORMS OF CANDIDATES FOR ELECTION AT THE BALLOT TO BE HELD AT THE ORDINARY SCIENTIFIC MEETING ON THURSDAY, DECEMBER 6th, 1928.

AINLEY, ARTHUR DONALD, Highfield House, Dobcross, nr. Oldham. English. Research Student. B.Sc. (1st Class Hons.), Manchester. (*Signed by*) Arthur Lapworth, Frederick Challenger, L. Klein, Arnold T. Peters, Alice C. Kellett.

ALCOCK, NELSON, c/o Messrs. C. C. Wakefield & Co., Ltd., Yorkshire House, Spring St., Sydney, Australia. British. Analytical Chemist. Four years as articled pupil to Mr. F. Higson, Manchester. Four years as Chief Chemist to Messrs. Huxley & Co., Oil Merchants, Liverpool. Nine years as Works Chemist to Messrs. C. C. Wakefield & Co., Ltd., Wakefield House, 30/32

Cheapside, London, E.C. 2., at their Liverpool works. (*Signed by*) Grove Johnson, E. A. Evans, Harold Moore.

ALIMCHANDANI, RUPCHAND LILARAM, Karnatak College, Dharwar, India. Indian. Lecturer of Chemistry. M.Sc. (Bombay). (1) Ten years' experience of teaching Chemistry in Colleges. (2) Joint or independent author of the following papers: (i) "Derivatives of Gallic Acid," etc., Parts I and II (*J.C.S.*, 1920, **117**; 1921, **119**); (ii) "Properties of Neighbouring Hydroxy-groups attached to a Benzene Nucleus" (*J.C.S.*, 1924, **125**, 539); (iii) "The Reduction of the Group $-CH(OH)\cdot CCl_3$" (*J. Ind. C.S.*, 1925, II, 1). (*Signed by*) A. N. Meldrum, A. R. Normand, M. Prasad.

AMSTELL, SIMON, 3, Ely Terrace, Mile End Rd., E. 1. British. Research Student at East London College. (*Signed by*) J. R. Partington, D. C. Jones, W. H. Patterson.

ANGUS, WILLIAM ROGIE, 11, Chattan Place, Aberdeen, Scotland. British. Research Student in Chemistry, University College, London. M.A., B.Sc. (Aberdeen), A.I.C. One year's research at Aberdeen University on "The Stability of Racemates." (*Signed by*) Alex Findlay, F. G. Donnan, T. Harold Reade, R. B. Strathdee.

BRETTLE, OWEN STANLEY, Red Hall Road, Lower Gornal, nr. Dudley. British. Assistant Gas Engineer and Manager. Nine years' practical experience in the chemical and technical control of chemical and gasworks plant. Five years' Assistant Engineer and Manager of Sedgley Gas Department, with extensive experience in chemical and technical matters relative thereto. Three years' experience in the constructional side of chemical plant. Holder of numerous certificates (Ordinary and Advanced Grades) of theoretical and practical inorganic chemistry, gas engineering, electrical engineering, and building science. Teacher of building science under Wolverhampton Technical College. (*Signed by*) Joseph Poulson, T. H. Poulson, Ernest Hardiker.

BROOKS, WILLIAM, 473, Halliwell Road, Bolton, Lancs. English. Manufacturing Chemist. Thirty years' experience as a Manufacturing Chemist. One of the two founders in 1906 of the firm of Marsh, Brooks & Co., Bolton, specialists for the supply of pharmaceutical preparations for the medical profession. (*Signed by*) Harcourt Phillips, Jno. L. Whiteside, Thos. Aspinall.

BUTTERWORTH, ALBERT JAMES, 44, Hind Street, E. 14. English. B.Sc. (London). Student at East London College since Sept. 1926. (*Signed by*) J. R. Partington, W. H. Patterson, D. C. Jones, F. E. King.

CAMPBELL, DUNCAN ARTHUR, Roseleigh, Speldhurst, Tunbridge Wells, Kent. British. Lecturer of Chemistry. M.Sc.Tech. Manchester, B.Sc. London. Blackpool Technical School, 1922–26. Lincoln Technical College, 1926–present. Associate of Institute of Chemistry. (*Signed by*) J. B. Firth, B. D. Shaw, E. B. R. Prideaux, F. S. Kipping.

CHARD, CHARLES ERNEST, 53, Eleanor Rd., Stratford, E. 15. English. Teacher (Science Master). B.Sc. London (1st Class). Teachers' Diploma (Cambridge). Science Master, Plaistow Secondary School, 1928. Student at Southampton University College, 1924–27. (*Signed by*) D. R. Boyd, D. V. N. Hardy, H. H. Hatt.

COCKBURN, JOSEPH GEORGE, 34, Cambridge Terrace, Gateshead-on-Tyne. English. Post-graduate Research Student. B.Sc. Durham (1st Class Hons.). (*Signed by*) G. R. Clemo, Richard Raper, R. D. Haworth, H. V. A. Briscoe.

COHEN, AARON, 114, Langdale Mansions, E. 1. British. Research Student. B.Sc. Hons. Chemistry (1st Class), London University. Professor's

Research Assistant, Chemistry Research Dept., King's College, London. (*Signed by*) Samuel Smiles, A. J. Allmand, K. C. Roberts.

CRUMMACK, GEORGE CECIL, 130, Ash Road, Headingley, Leeds. British. Pharmaceutical Chemist on staff of United Drug Co., Ltd. Major examination Pharm. Soc., Great Britain. Student of the late Professor Arthur W. Crossley, F.R.S., 1908–9. Examination of Faeces and Urine for Arsenic after 606 Treatment in 1915–16. Report sent to A.D.M.S., Portsmouth. (Brought to notice for valuable services rendered during war.) I am desirous of receiving the publications of the Society. (*Signed by*) F. Pilkington Sargeant, Wm. Forster, Frank Browne.

DICKINS, ARTHUR WILLIAM MARTIN, 2, Rotherwick Court, Rotherwick Road, Golder's Green, N.W. 4. British. Chemical Manufacturer. Diploma Finsbury Technical College. Researches in the manufacture of British Photographic Reagents as Metol Amidol Glycin, etc. (*Signed by*) O. Silberrad, T. Slater Price, F. F. Renwick, S. O. Rawling.

DIXON, WILLIAM LESLIE, 14, Melrose Road, Merton Park, S.W. 19. British. Assistant editor *The Chemist and Druggist*. Qualifying examination of the Pharmaceutical Society. Experience in laboratories of manufacturing chemists. (*Signed by*) George P. Forrester, Arthur E. Pitt, Sydney A. Mann.

DOMLEO, ALLAN, "Charnwood," Southfield Park, Harrow, Middlesex. British. Technical Assistant. M.Sc. (London). B.Sc. (London), Hons. in Chemistry, 1920. Engaged in research in Organic Chemistry at Battersea Polytechnic, 1920–24. Examiner in H.M. Patent Office (Organic Chemistry), 1920–28. With Joseph Kenyon, *J.C.S.*, 1926, 1841. (*Signed by*) J. Kenyon, A. Houssa, S. Greenberg, Henry Phillips, F. Bell.

GODBOLE, SHANKAR NAGNATH, Nagpur (India), College of Science, Nagpur, C.P. Indian. Professor of Chemistry. B.Sc. (Bombay), M.Sc. (Allahabad). Assistant Professor of Chemistry, 1913–24. Professor of Chemistry, 1924–onwards. Also Chemical Examiner of Explosives to C.P. Govt. from 1927. (*Signed by*) D. V. Bal, A. R. P. Aiyer, R. N. Kayasth.

GORDON, JOHN GRANT, 23, Jenner House, Hunter Street, W.C. 1. British. Chemist and Technical Director, Pioneer Chemical Works, Stratford, E. Wish to receive the Society's publications, to use the Library, and to attend the meetings of the Society. (*Signed by*) G. F. Merson, Thos. Tucker, J. F. Tocher.

GROOCOCK, CONSTANCE MARY, 25, St. Peter's Mount, Bramley, Leeds. British. Research Student. B.Sc. 1st Class Hons. Chemistry, Leeds. Research Student in Organic Chemistry at Leeds University. (*Signed by*) C. K. Ingold, J. W. Baker, H. Burton.

HEAD, FRANK SAMUEL HENRY, 149, Fillebrook Rd., Leytonstone, E. 11. English. Research Student, East London College. B.Sc. London, 1st Class Hons. in Chemistry. (*Signed by*) J. R. Partington, A. Robertson, F. E. King.

HENLEY, ROSALIND VENETIA, 9, Oxford Square, W. 2. English. Student of Chemistry at Bedford College. I wish to keep abreast of the advance of chemistry by attending the meetings and receiving the Journal. A joint paper has been presented to the Chemical Society for publication. (*Signed by*) James F. Spencer, E. E. Turner, Florence R. Shaw.

HOPTON, GERALD UERN, 25, Museum Road, Oxford. English. Research Student. B.A. Oxon. Passed Part I (Hons.) in Chemistry at Oxford. Scholar of New College, Oxford. (*Signed by*) W. H. Perkin, J. Masson Gulland, S. G. P. Plant, E. Hope.

HURTLEY, WILLIAM ROBERT HARDY, 28, Chestnut Road, W. Norwood,

S.E. 27. British. Demonstrator in Chemistry, King's College, London. B.Sc., Ph.D., King's College, University of London. (Joint author) *J.C.S.*, 1926, 1821, 2263; 1927, 534. (*Signed by*) Samuel Smiles, A. J. Allmand, W. H. Hurtley.

JACKSON, RALPH ANDERSON, 46, St. James's Road, Carlisle. English. Works Chemist to Messrs. Hudson Scott & Sons, Ltd., Colour Printers, Carlisle. Scholar of Peterhouse, Cambridge. Natural Sciences Tripos, Part I, Class II; Part II (chemistry), Class II. (*Signed by*) George H. Martin, Hamilton McCombie, Harold A. Scarborough.

JESSOP, JOE ARTHUR, 2, Bradley Terrace, Shadwell Lane, Moortown, Leeds, Yorks. British. Research Student in Organic Chemistry. B.Sc. 1st Class Hons. Chemistry, Leeds. (*Signed by*) C. K. Ingold, J. W. Baker, E. Rothstein.

KAMIL, ZÉNAB, Bedford College, Regent's Park, N.W. 1. Egyptian. Student. Honours Student of Chemistry at Bedford College. (*Signed by*) James F. Spencer, Ivy W. Rogers, Mollie Barr.

KRISHNASWAMI, KOLAR RAMAKRISHNAIYER, 21, Cromwell Road, S. Kensington, S.W. 7. Hindu. Research Student, University College, London. B.A., Mysore University (India). Associate of the Indian Institute of Science, Bangalore, India. Assistant Chemist, Indian Institute of Science, Bangalore, India. "The Atomic Weight of Antimony from Different Sources," *J.C.S.*, 1927, 2534. (*Signed by*) J. L. Simonsen, C. S. Gibson, W. M. Colles.

LEONARD, JULIAN MAYNARD, Firfield, 1, Lindfield Gardens, Hampstead, N.W. 3. British. Chemical Manufacturer. Partner in Carless, Capel & Leonard. Desires to receive the publications of the Society and to use the Library. (*Signed by*) Francis H. Carr, Thos. Macara, L. E. Campbell, Francis H. Banfield.

LEVI, ALFRED AARON, 2, Ormonde Terrace, Regent's Park, N.W. 8. British. M.Sc. (New Zealand University). Research Student. (*Signed by*) Samuel Smiles, W. B. Price, K. C. Roberts.

MALLEN, CATHERINE ELEANOR, The Red House, Beechwood Terrace, Sunderland. British. Lecturer. M.A., Cantab. Lecturer in Chemistry at Armstrong College, Newcastle-on-Tyne. (*Signed by*) R. D. Haworth, G. C. Leitch, H. V. A. Briscoe.

MANN, JASON THOMAS WILLIAM, The Homestead, Burcharbro Rd., Abbey Wood, S.E. 2. British. I am working under Professor J. F. Thorpe in the research laboratories of the Imperial College. A.R.C.S. (2nd Class Hons.), also 2nd Class Special B.Sc. will be awarded me after a further year at College. I am at present working for a Ph.D. degree. (*Signed by*) Jocelyn Thorpe, M. A. Whiteley, R. P. Linstead, R. F. Hunter.

MARGINSON, CHARLES CARR, The Homestead, Whitestakes, near Preston. English. Company Director. B.Sc. (Hons. Chemistry, Manchester). Inter. B.Sc. (London). In order to keep abreast of modern chemistry. (*Signed by*) Arthur Lapworth, R. Robinson, Frederick Challenger, D. H. Bangham.

MARTIN, ALBERT EDWARD, 47, Mildmay Grove, N. 1. British. Research Student. B.Sc. (Lond.), 2nd Class Hons. Chemistry. (*Signed by*) J. R. Partington, W. H. Patterson, D. C. Jones.

MENON, KOTTIAZATH NARAYANA, 55, Parliament Hill, Hampstead, N.W. 3. British Indian. Research Chemist under Prof. Robinson. M.Sc. (Bombay). *J.C.S.*, 1926, 2247; 1928, 431 (part author with Prof. J. L. Simonsen). (*Signed by*) Robert Robinson, J. L. Simonsen, W. M. Colles.

MURRAY, MARTHA ELIZABETH, 90, Channel Street, Galashiels, Selkirkshire.

British. Analytical Chemist. B.Sc. (2nd Class Hons., Lond.), A.R.C.Sc.I., A.I.C. Research Chemist and Lecturer in Chemistry at the Scottish Woollen Technical College, Galashiels, 1924–28. (*Signed by*) A. G. G. Leonard, W. E. Adeney, A. O'Farrelly.

OXFORD, ALBERT EDWARD, 7, Talbotville Rd., Broad Green, Liverpool. English. Research Chemist at War Office Research Establishment, Sutton Oak, Lancs. M.Sc., Ph.D. (Manchester). *J.C.S.*, 1926, 2004; 1927, 1964, 2239; (with Professor Robinson), *J.C.S.*, 1926, 383, 401; (with Professors Perkin and Robinson), *J.C.S.*, 1927, 2389; (with Professor Raper), *J.C.S.*, 1927, 417. (*Signed by*) Robert Robinson, James D. Fulton, Alex Robertson, Reginald C. Fawcett.

PATTERSON, NELLIE, 23, Ferndene Rd., Herne Hill, S.E. 24. British. Pharmaceutical Chemist. Major Diploma of the Pharmaceutical Society of Great Britain. Pharmacist, Tropical Diseases Hospital, Endsleigh Gardens, W.C. 1. I wish to attend the lectures and receive the publications of the Chemical Society. (*Signed by*) Francis H. Carr, Charles Alex. Hill, J. Langford Moore.

POSTELL, RONALD, 130, St. John's Avenue, Bridlington, Yorks. British. Schoolmaster. B.A. (Hons. in Chemistry, Physics, and Geology), Cambridge. Late Exhibitioner in Natural Sciences, Trinity College, Cambridge. Honours course in chemistry, Cambridge University, 1925–28. Chemistry Master, Aldenham School, June 1928 to date. (*Signed by*) W. J. Pope, W. H. Mills, F. B. Kipping.

RUSSELL, ALFRED, Department of Chemistry, The Queen's University, Belfast, N.I. British. Assistant, Dept. of Chemistry, Queen's University, Belfast. B.Sc. (1st Class), Belfast. (*Signed by*) A. W. Stewart, J. K. Marsh, H. Graham.

SAINT, SIDNEY JOHN, Government Laboratory, Barbados, B.W.I. British. Agricultural Chemist. B.Sc. (London), A.I.C. Formerly Lecturer in Agricultural Chemistry, Leeds University (1922–26). (With N. M. Comber), *Soil Science*, 1924, xviii, 131; *Trans. Faraday Soc.*, 1925, xx; *Proc. Second Comm. Inter. Soc. Soil Sci.*, 1926, Vol. A. (*Signed by*) H. Bassett, H. A. D. Neville, J. W. Dodgson.

SAUNDERS, RUPERT HENRY, "Littlecot," Windsor Rd., Slough, Buckinghamshire. British. Assistant Engineer and Manager, Slough Gas and Coke Co. Chief Chemist to Worthing Gas Co. Control of laboratories for analytical work and research, with special reference to effluents, tars, and ammonium sulphate. Subsequently as Assistant Engineer and Manager to the Worthing Gas Co., and now as Assistant Engineer and Manager to the Slough Gas Co., responsible for the efficiency of and the results obtained from the various manufacturing and by-products plant at their respective works. (*Signed by*) F. Napier Sutton, M. C. Clutterbuck, H. Houlston Morgan.

SELIKMAN, HARRY, 46, Harpur Avenue, Benoni, Transvaal. British. Research Student. B.Sc., Witwatersrand University, Johannesburg. Desire to keep in touch with the advance and development of chemical science. (*Signed by*) Henry Stephen, O. G. Backeberg, J. A. Wilkinson.

SHETH, KANTILAL MAGANLAL, Assistant Manager, Shree Shakti Alkali Works, Dhrangadhra, Kathiawad, India. Hindoo. State Chemist. M.Sc. (Bombay), A.I.I.Sc. (Bangalore). 1. One of the authors of the "Extraction of Caffeine," *J. Ind. Inst. Sci.*, Vol. V, Part XIII. 2. Analytical and Works Chemist in a Hydrogenation Factory, Bombay. 3. Enormous amount of experimental work carried out in connection with the manufacture of salt and by-products (soda, magnesium chloride, magnesium sulphate, etc.), *vide*

book on Salt by Kapilram H. Vakil, M.Sc., B.A., F.I.C. 4. Lecturer in Sir Ajitsinhji High School, with brilliant record for the High School in Bombay University. 5. State Chemist and Assistant Manager. (*Signed by*) K. G. Naik, M. Prasad, A. R. Normand.

SIMPSON, HENRY GEORGE, 21, Truro Road, Wood Green, N. 22. British. Research student at East London College. London University B.Sc. (General), 1st Class Hons. in Physics, Pure Mathematics, and Chemistry. London University B.Sc. (Special), 1st Class Hons. in Chemistry. (*Signed by*) J. R. Partington, W. H. Patterson, F. E. King.

SMITH, JOHN WILLIAM, 70, Verdant Lane, S.E. 6. British. Research Student. B.Sc. London (1st Class Hons. Chemistry), University College, London. Three years' experience as research student in Department of Chemistry, University College, London. Thesis for Ph.D. degree submitted to University of London. "The Vapour Pressure of Intensively Dried Nitrogen Tetroxide," *J.C.S.*, 1927, 867; "The Effect of Intensive Drying on the System Nitrogen Peroxide–Nitric Oxide–Oxygen," sent for publication; "The Adsorption of Vapours on an Amalgamated Platinum Surface," sent for publication. (*Signed by*) F. G. Donnan, L. F. Gilbert, H. Terrey.

SOLOMON, WILLIAM, 14, Finsen Rd., S.E. 5. British. Chemist. Special B.Sc. (Lond.) (1st Class Hons. Chemistry). Student at Birkbeck College (University of London). I desire to receive the current literature on pure chemistry. (*Signed by*) George W. Ferguson, Samuel Sugden, George Senter, F. J. Thorneycroft.

SUMNER, CYRIL GORDON, "Willow Dene," 53, St. Thomas' Road, Chorley, Lancs. British. Research Student, Victoria University of Manchester. B.Sc., 1st Class Hons. in Chemistry, 1925; M.Sc., 1926 (Victoria University of Manchester). Three years' research experience (under direction of D. C. Henry). Work so far unpublished. Subject: A New Method for the Study of Cataphoresis. Awards: Graduate Prize and Leblanc Medal in Applied Electrochemistry, 1925. Beyer Fellowship, 1927–28 (Victoria University of Manchester). Senior Research Award, 1928–31 (Dept. of Scientific and Industrial Research). (*Signed by*) Arthur Lapworth, D. C. Henry, Fred Fairbrother.

THAKUR, RAMSIMHA, Mandla Fort, Mandla, C.P., India. Indian. Research Scholar in Organic Chemistry at Royal College of Science. B.Sc. (Nagpur), M.Sc. (Nagpur), first in University. (*Signed by*) G. A. R. Kon, I. Vogel, W. E. Hugh.

TIPLER, ALBERT FRED, 13B, Harley Street, Bow, E. 3. English. Research Student B.Sc. (Special), London, 1st Class Hons. Student at East London College since Sept. 1926. (*Signed by*) J. R. Partington, W. H. Patterson, F. E. King, A. Robertson.

VAUGHAN, ARTHUR ERNEST, jun., Quebec Lodge, Regent Road, Birkdale, near Southport. British. Brewer and Analytical Chemist. Certificate of Brewing and Malting, University of Birmingham; and desirous of receiving the Society's journal. (*Signed by*) Herbert Hobson, G. D. Clarkson, C. E. Sutcliffe.

VENKAJEE, TEKUMALLA, Rajahmundry, Madras Presidency, India (present address, c/o The Laboratories, The Valleyfield Paper Mills, Penicuik, Midlothian). Indian. Chemist, The Carnatic Paper Mills, Ltd., Rajahmundry, India. B.A., Madras University, with Chemistry as the special subject. Honorary Research Student in the laboratories of the Maharaja's College, Vizianagram, India. Special student of Mr. William Raitt, F.C.S., M.I.Chem.E., in cellulose chemistry and paper technology. Trained in civil,

mechanical, and chemical engineering in the C.P. Mills under the American chemical engineer, Mr. E. P. Wood. Articles on "Sabai" grass and "Bamboo" in the Paper Trade Journal, New York. Manufacture of "Cotton Seed Oil and Paper from Cotton Stalks" in Andhrapatrika Annual, 1919. (*Signed by*) William Raitt, Madyar Gopel Rao, Navin Chandra Mittal.

WEBSTER, GEORGE REGINALD, 8, Marlborough Road, Bearwood, Birmingham. British. Assistant Works Manager (Branch Works). 1925, investigator and author of prize thesis, "Aluminium Soldering, Welding, and Fluxes," Birmingham Metallurgical Soc., also paper "Useful Alloys of Aluminium, and their Properties," *J. Inst. Brit. Foundrymen*, Nov. 4th, 1926. Position, Assistant Works Manager, Metallurgical Chemist, and Engineer. I desire also to attend the meetings, etc., and to keep in touch with current research. (*Signed by*) Ernest Hardiker, Joseph Lones, Arthur Adams.

WHITE, MARGARET KATHERINE, Northern Polytechnic, N. 7. English. Librarian, Northern Polytechnic, N. 7. B.Sc., 2nd Class Hons. Chemistry (London), M.Sc. Lond. Co-author with Dr. T. J. Drakeley, F.C.S., of three papers published in the *Journal of Agricultural Science*, Vol. 17, Pt. I, p. 118; Pt. III, p. 140; Vol. 18, Pt. III, p. 496; all dealing with the influence of breed, age, and period of lactation of the cow, on the yield and quality of the milk. (*Signed by*) T. J. Drakeley, D. H. Richardson, H. J. S. King.

WILLIAMS, WILLIAM DUDLEY, Cia Industrial y Comercial de Petroleo, Canadon Rosales, Comodoro Rivadavia, Argentina. British. Chemist. B.Sc. (Lond.), 1st Class Hons. Chemistry, F.I.C. Part-time Lecturer in Chemistry, Swansea Technical College, 1922–24. Chemist with Anglo-Persian Oil Co., Ltd., 1923 onwards. Part author of paper "Action of Chlorides of Phosphorus on Chlorodimethyldihydroresorcinol," *J.C.S.*, 1922, 121. (*Signed by*) J. E. Coates, L. E. Hinkel, E. E. Ayling, D. H. Hey.

WYNNE-JONES, WILLIAM FRANCIS KENRICK, The University, Reading. British. Lecturer in Chemistry. *J.C.S.*, 1924, 1031; 1928, 1230. (*Signed by*) D. Roy Maxted, J. W. Dodgson, H. Bassett.

The following Certificates have been authorised by the Council for presentation to ballot under Bye-Law I (2):

JINDAL, SHANKAR LAL, 101–118, Talag Mahal, Cawnpore, U.P., India. Indian. Professor of Chemistry. M.Sc. Allahabad University. Contributed articles to the *Chemical News* and *Nature*, and the author of *A Text-book of Inorganic Chemistry* for the Intermediate Classes and five years' teaching experience. (*Signed by*) N. R. Dhar, K. P. Chatterjee.

LIPWORTH, ALEXANDER, 23, Kerk Street, Johannesburg, South Africa (postal address, P.O. Box 5084, Johannesburg). British. Chemist and Druggist, Transvaal, South Africa. Interested in chemical research, being Managing Director of a wholesale firm of Manufacturing Chemists. (*Signed by*) Edward A. Andrews.

MAR, PETER, 296, Ellen Street, Winnipeg, Manitoba, Canada. Born Victoria, B.C., Canada. Instructor in Physics (Lingnaam University, Canton, China). B.Sc. (University of Manitoba (1922), M.A. (Oskaloosa College), M.Sc. (University of Manitoba (1924). Instructor in Sciences (Union Middle School, Canton, China) (1923–26). Fellowship China Medical Board of the Rockefeller Foundation (1925–26) at Pekin. (*Signed by*) Matthew A. Parker.

SAW, WALTER WILLIAM, c/o Vacuum Oil Co., Pty., Ltd., Perth, Western Australia. Australian. Analytical Chemist. B.Sc. (Western Australia). Associate of the Australian Chemical Institute. Five years' as Chemist with

Government Chemical Laboratory. One year as Chemist with Vacuum Oil Co., Pty., Ltd. (*Signed by*) N. T. M. Wilsmore, Edward S. Simpson.

YAMASHITA, TAIZO, Asamacho 4, Mukden (Japanese Concession), China. Japanese. Professor of S. M. Medical College. Doctor (Imperial University of Tokyo). (*Signed by*) Yasuhiko Asahina.

ADDITIONS TO THE LIBRARY.

PROCEEDINGS

OF THE

CHEMICAL SOCIETY.

Extra Meeting held at the Institution of Mechanical Engineers, Storey's Gate, Westminster, S.W.1, on Thursday, November 29th, 1928, at 5.30 p.m., the President, Professor J. F. THORPE, C.B.E., D.Sc., F.R.S., in the Chair.

The PRESIDENT stated that the Liversidge Lectures had been founded in accordance with the will of the late Professor Liversidge of the University of Sydney. By the terms of this will a sum of money was left to the Society in order to establish an annual lecture, in connection with similar lectures to be provided by the University of Sydney, The Royal Society of New South Wales, and The Australasian Association for the Advancement of Science. The PRESIDENT then read the clauses in the will dealing with the lectureships and stated that the Council had also established another series of lectures, called the Pedler Lectures, to perpetuate the memory of Sir Alexander Pedler, a generous benefactor to this Society. He said that the Council had decided that the Liversidge Lecture should be in the domain of Physical and Inorganic Chemistry and the Pedler Lecture in Organic Chemistry.

The PRESIDENT then called upon Professor Donnan to deliver his lecture entitled : " Physical Chemistry in the Service of Biology."

At the conclusion of the lecture, a vote of thanks to the lecturer was proposed by Mr. A. Chaston Chapman, seconded by Professor J. C. Philip, and carried unanimously, Professor Donnan making acknowledgment.

Ordinary Scientific Meeting, Thursday, December 6th, 1928, at 8 p.m., Professor J. F. THORPE, C.B.E., D.Sc., F.R.S., President, in the Chair.

Certificates were read for the first time in favour of :—

Osman Achmatowicz, D.Chem., 348, Banbury Road, Oxford.
Harry James Barber, B.Sc., Ph.D., 30, Bridgeman Road, Teddington.

George Discombe, 48, King Edwards Grove, Teddington.
Bertram John Frederick Dorrington, B.Sc., 287, New Cross Road, S.E.14.
Eustace Leonard Gates-Warren, B.Sc., 17, Chatsworth Road, West Norwood, S.E. 27.
John Mildred Deane Gauntlett, M.Sc., St. Edward's School, Oxford.
Gordon Rupert Gedye, B.A., Trinity Hall, Cambridge.
Mary Stephen Lesslie, M.A., B.Sc., Ph.D., Bedford College, Regent's Park, N.W. 1.
Arthur James Mee, B.A., B.Sc., 62, Rectory Grove, S.E. 18.
Hermy Richard Napp, 3 & 4, Clements Inn, W.C. 2.
George David Parkes, B.Sc., M.A., D.Phil., Keble College, Oxford.
Chaturbhai Shankarbhai Patel, B.A., M.Sc., 2, Hyde Terrace, Leeds.
John Powdrill, 20, Catlow Hall Street, Oswaldtwistle.
Walter Gunnar Theodor Qvist, D.Phil., Abo Academy, Abo, Finland.
David Roberts, B.Sc., 37, Water Street, Llanllechid, Bangor.
James Walker Rowe, Malton, Holmesdale Road, Orpington.
Richard Stanley Wrey Thorne, B.Sc., A.R.C.S., 51, Newlyn Road, N. 17.
William Harold Juggins Vernon, D.Sc., Ph.D., F.I.C., 6, High Street, Wimbledon, S.W. 19.
Frederick James Wilkins, M.Sc., 4, Humberstone Road, Cambridge.

Mr. W. H. Gray and Dr. H. Hunter, were elected Scrutators, and a ballot for the election of Fellows was held. The following were subsequently declared elected :—

Arthur Donald Ainley, B.Sc.
Nelson Alcock.
Rupchand Lilaram Alimchandani, M.Sc.
Simon Amstell.
William Rogie Angus, M.A., B.Sc., A.I.C.
Owen Stanley Brettle.
William Brooks.
Albert James Butterworth, B.Sc.
Duncan Arthur Campbell, M.Sc. Tech., B.Sc., A.I.C.
Charles Ernest Chard, B.Sc.
Joseph George Cockburn, B.Sc.
Aaron Cohen, B.Sc.
George Cecil Crummack.
Arthur William Martin Dickins.
William Leslie Dixon.
Allan Domleo, M.Sc.
Shankar Nagnath Godbole, M.Sc.
John Grant Gordon.
Constance Mary Groocock, B.Sc.
Frank Samuel Henry Head, B.Sc.
Rosalind Venetia Henley.
Gerald Uern Hopton, B.A.
William Robert Hardy Hurtley, B.Sc., Ph.D.
Ralph Anderson Jackson, B.A.
Joe Arthur Jessop, B.Sc.
Shankar Lal Jindal, M.Sc.
Zénab Kamil.
Kolar Ramakrishnaiyer Krishnaswami, B.A.
Julian Maynard Leonard.
Alfred Aaron Levi, M.Sc.
Alexander Lipworth.
Catherine Eleanor Mallen, M.A.
Jason Thomas William Mann, A.R.C.S.
Charles Carr Marginson, B.Sc.
Peter Mar, M.A., M.Sc.
Albert Edward Martin, B.Sc.
Kottiazath Narayana Menon, M.Sc.
Martha Elizabeth Murray, B.Sc., A.R.C.Sc.I., A.I.C.
Albert Edward Oxford, M.Sc., Ph.D.
Nellie Patterson.
Ronald Postell, B.A.
Alfred Russell, B.Sc.
Sidney John Saint, B.Sc., A.I.C.
Rupert Henry Saunders.
Walter William Saw, B.Sc.
Harry Selikman, B.Sc.
Kantilal Maganlal Sheth, M.Sc.
Henry George Simpson, B.Sc.
John William Smith, B.Sc.

William Solomon, B.Sc.
Cyril Gordon Sumner, M.Sc.
Ram Simha Thakur, M.Sc.
Albert Fred Tipler, B.Sc.
Arthur Ernest Vaughan.
Tekumalla Venkajee, B.A.
George Reginald Webster.
Margaret Katherine White, M.Sc.
William Dudley Williams, B.Sc., F.I.C.
William Francis Kenrick Wynne-Jones.
Taizo Yamashita.

The following papers were read :—

" The mechanism of corrosion." By U. R. EVANS.

" Properties of conjugated compounds. Part VI. The dibromination products of cyclic butadienes." By E. H. FARMER and W. D. SCOTT.

" The stereoisomerism of disulphoxides and related substances. Part IV. Di- and tri-sulphoxides of trimethylenetrisulphide." By E. V. BELL and G. M. BENNETT.

" The structure of organic molecular compounds." By G. M. BENNETT and G. H. WILLIS.

" Hexa-aminobenzene." By B. FLÜRSCHEIM and E. L. HOLMES.

Ordinary Scientific Meeting, Thursday, December 20th, 1928, at 8 p.m., Professor J. F. THORPE, C.B.E., D.Sc., F.R.S., President, in the Chair.

The PRESIDENT referred to the loss sustained by the Society, through death, of the following Fellows :—

	Elected.	Died.
Alfred Anderson	Dec. 2nd, 1915.	June 22nd.
John H. B. Jenkins	May 5th, 1892.	Dec. 11th.
John Edward L. Moore	Dec. 5th, 1907.	Dec. 15th.
Joseph Tcherniac	April 4th, 1878.	Dec. 11th.

It was announced that :—

1. The Subscription list to the Liebig Portrait Fund is still open and that subscriptions should be sent as soon as possible to the Treasurer.

2. Dr. O. Rosenheim, of the National Institute for Medical Research, had presented to the Society two manuscript letters of Liebig.

3. The PRESIDENT, Sir William Pope, K.B.E., F.R.S., and Prof. C. S. Gibson, O.B.E., had been appointed to represent the Society on the Federal Council of Pure and Applied Chemistry for 1929.

The following were formally admitted Fellows of the Chemical Society : A. A. Levi, A. Cohen, Jason T. W. Mann, J. W. Smith, G. R. Webster, K. R. Krishnaswami, and K. N. Menon.

Certificates were read for the first time in favour of :

Leslie Alderman Elson, B.Sc., A.I.C., 27, Truro Road, Wood Green, N. 22.
Masao Fukuda, Chemical Institute, Tohoku Imperial University, Sendai, Japan.
Sidney Herbert Jones, 85, St. George's Road, S.W. 1.
Thomas Edward Lescher, O.B.E., 16, Oxford Road, Birkdale, Lancs.
Charles Henry Maile, 3, Aubrey Walk, Kensington, W. 8.
Alfred Herbert Spong, B.Sc., Westminster College, Horseferry Road, S.W. 1.
Edgar Stedman, D.Sc., Ph.D., 12, Woodburn Terrace, Edinburgh.
John Norman Williams, A.M.I.Mech.E., 58, Alfriston Road, Clapham Common, S.W. 11.
Olli Viljo Anton Wuorinen, M.A., 1, Westfield Road, Edgbaston, Birmingham.

The following Certificates have been authorised by the Council for presentation to ballot under Bye-Law I (2) :

Robert Douglas Coghill, George Street, Dunedin, New Zealand.
José Pascual, Prof., Universidad, Seville.
Alfred Wagner, Pesterzsebet, Hungary.

The following papers were read :

" Influence of poles and polar linkings on the course pursued by elimination reactions. Part II. Mechanism of exhaustive methylation (*continued*)." By C. K. INGOLD and C. C. N. VASS.

" Influence of poles and polar linkings on the course pursued by elimination reactions. Part III. A decomposition of dialkylsulphones." By G. W. FENTON and C. K. INGOLD.

" Influence of poles and polar linkings on tautomerism in the simple three-carbon system. Part I. Experiments illustrating prototropy and anionotropy in trialkylpropenylammonium derivatives." By C. K. INGOLD and E. ROTHSTEIN.

" Researches on residual affinity and co-ordination. Part XXXI. Molybdyl bis-β-diketones." By G. T. MORGAN and R. A. S. CASTELL.

" Interactions of selenium oxychloride and phenols." By G. T. MORGAN and F. H. BURSTALL.

" The parachor and chemical constitution. Part X. Singlet linkages in chelated co-ordination compounds." By S. SUGDEN.

The Council has made the following Grants from the Research Fund :

	£	s.	d.
Mutual solubility relations of methyl alcohol and saturated hydrocarbons. S. Amstell. (E. Lond. Coll.)	10	0	0
Stereoisomerism in polycyclic systems. B. K. Blount. (Oxford Univ.)	10	0	0
Electro-deposition of hydrogen and the measurement of the accessible areas of metallic surfaces. F. P. Bowden. (Cambridge Univ.)	10	0	0

	£	s.	d.
Physico-chemical studies of some of the rarer acids and their salts. H. T. S. Britton. (Exeter Univ. Coll.)	10	0	0
Additions to vinyl bromide and the properties of the substances obtained. G. N. Burkhardt. (Manchester Univ.)	10	0	0
Magnetic susceptibility of binary mixtures of organic liquids. (Miss) J. Cattermole. (Bedford Coll.)	6	0	0
Hydrogenation of conjugated compounds. C. M. Cawley. (Imperial Coll.)	10	0	0
Dynamics of surface action. F. H. Constable. (Cambridge Univ.)	20	0	0
Oxygen content of wrought iron and steel. C. H. Desch and H. G. Rains. (Sheffield Univ.)	10	0	0
Colour and fluorescence of the pyronine dyestuffs. A. N. Dey. (Imperial Coll.)	8	0	0
Preparation and properties of simple aliphatic unsaturated ketones with particular reference to isomeric change. E. N. Eccott (Imperial Coll.)	10	0	0
Quantum efficiency measurements on the induction period of the hydrogen–chlorine reaction. J. G. A. Griffiths. (Cambridge Univ.)	10	0	0
Mechanism of permanganate oxidation. (Miss) C. M. Groocock. (Leeds Univ.)	8	0	0
Action of Grignard compounds upon substituted *cyclo*hexene oxides and the preparation of substituted *cyclo*hexanones. F. S. H. Head. (E. Lond. Coll.)	10	0	0
Influence of the solvent in reaction velocity in its bearing on the quantum theory. F. W. Hodges. (Chelsea Polytechnic)...	5	0	0
Determination of the mutual solubility curves of secondary and *iso*butyl alcohols in water, and of the four isomeric butyl alcohols in non-polar solvents. D. C. Jones. (E. Lond. Coll.)	15	0	0
Synthesis of rubiadin and rubiadin glucoside. E. T. Jones. (E. Lond. Coll.)	8	0	0
Chemistry of β-lactones. A. Kandiah. (Imperial Coll.) ...	10	0	0
Orientation by positive poles. R. J. W. Le Fèvre. Univ. Coll., London)	16	0	0
Isomeric changes in unsaturated dibasic acids. J. T. W. Mann. (Imperial Coll.)	10	0	0
Synthesis of the glucoside of 6 : 6′-dibromoindigo. L. W. Mullinger. (E. Lond. Coll.)	8	0	0
Chemistry of 2 : 3- and 4-methyl *cyclo*hexanones. (Miss) M. P. Oommen. (Imperial Coll.)	10	0	0
Tautomerism of unsaturated acids. L. G. B. Parsons. (Imperial Coll.)	7	10	0
Side-chain reactivity in aromatic systems. C. S. Patel. (Leeds Univ.)	12	0	0
Effect of so-called " strainless " rings on the carbon tetrahedral angle. K. A. N. Rao. (Imperial Coll.)	10	0	0
Constitution and synthesis of certain glucosides, and the synthesis of certain hydroxy-acids. A. Robertson. (E. Lond. Coll.)	30	0	0
Effects of poles in the simple three-carbon system. E. Rothstein. (Leeds Univ.)	20	0	0
Investigations of diphenyl compounds. (Miss) F. R. Shaw. (Bedford Coll.)	10	0	0

	£	s.	d.
Symmetrical triad systems. C. W. Shoppee. (Leeds Univ.) ...	15	0	0
E.M.F. measurements in anhydrous ethyl alcohol. H. G. Simpson. (E. Lond. Coll.)	10	0	0
Nitrations of unsymmetrical ethers of quinol. J. C. Smith. (Oxford Univ.)	7	10	0
Three-carbon tautomerism. R. S. Thakur. (Imperial Coll.) ...	10	0	0
Certain additive properties of piperylene and isoprene. R. S. W. Thorne. (Imperial Coll.)	10	0	0
Heats of adsorption at low pressures. A. F. H. Ward. (Cambridge Univ.)	10	0	0
Investigations on the bivalency of carbon. A. M. Ward. (Sir John Cass Tech. Institute)	5	0	0
Synthesis of xanthones and of xanthone glucosides. R. B. Waters. (E. Lond. Coll.)	10	0	0
Substitution in the benzophenone and diphenylmethane series. W. A. Waters. (Durham Univ.)	5	0	0
Reactions of halogens with certain organic acids and acid anhydrides. H. B. Watson. (Bangor Univ. Coll.)	15	0	0
	£411	0	0

ANNUAL REPORTS ON THE PROGRESS OF CHEMISTRY.

Fellows are reminded that application for the Annual Reports for 1928, Volume XXV, at 5*s.* 6*d.* per copy should be received by Mr. S. E. Carr without delay. Application must be accompanied by a remittance for 5*s.* 6*d.*

List of Papers, or Abstracts thereof, received between November 15th and December 20th, 1928. (This List does not include the titles of papers which have been read at an Ordinary Scientific Meeting, or which have appeared in the Journal.)

"The alkalinity of soap solutions as measured by indicators." By J. W. McBain and K. Hay.

"The formation of Liesegang rings as a periodic coagulation phenomenon." By J. R. I. Hepburn.

"The degradation of *l*-arabinose." By V. Deulofeu and R. J. Selva.

"Activated magnesium." By P. Maitland.

"*N*-Substituted derivatives of piperazine and ethylenediamine. Part I. The preparation of *N*-monosubstituted derivatives of piperazine and ethylenediamine." By T. S. Moore, M. Boyle, and V. M. Thorn.

"A steam drying oven with detachable base." By H. J. S. Sand.

"Constitutional influences on the conversion of azo-naphthols into their azo-sulphites and their bearing on the structure of α- and β-naphthol." By A. T. King.

"Tertiary phosphines containing the *n*-butyl radical." By W. C. DAVIES and W. J. JONES.

"The reaction between ferric sulphate solution and cuprous sulphide." By L. WHITBY.

"The decomposition of methane. Part I." By C. W. H. JONES.

"Note on the influence of colloids on the precipitation of salts." By R. DICKINSON.

"The reduction of *m*-nitrobenzaldehyde and some of its derivatives in neutral solution." By W. M. CUMMING and J. C. EATON.

"Non-existence of isomerism among the dialkyltelluronium dihalides." By H. D. K. DREW.

"The formation of quaternary ammonium compounds in solution. Part I. Influence of polarity of the solvent." By R. N. KERR.

"The synthesis of *meso*-alkyl and *meso*-aryl anthracene derivatives. Part V." By E. DE B. BARNETT and N. F. GOODWAY.

"The quaternary system: lead acetate–lead chloride–acetic acid–water at 25°." By K. SANDVED.

"The mechanism of thermal decomposition of the normal paraffins." By E. N. HAGUE and R. V. WHEELER.

"Effect of the addition of hydrogen and water on the radiation emitted from the carbon monoxide flame." By W. E. GARNER and F. ROFFEY.

"Synthetical experiments in the *iso*flavone group. Part IV. A synthesis of 2-methylirigenol." By W. BAKER and R. ROBINSON.

"Studies in the phenylsuccinic acid series. Part IX. The resolution of *r*-diphenylsuccin-α- and -β-naphthylamic acids into their optical antipodes." By H. WREN and E. WRIGHT.

"Studies in the phenylsuccinic acid series. Part X. Racemisation phenomena observed during the action of water and bases on the optically active diphenylsuccinic anhydrides." By H. WREN and E. WRIGHT.

"Note on the preparation of quinaldinyl chloride and quinaldinyl acetoacetic ester." By D. L. HAMMICK and W. P. DICKINSON.

"A synthesis of *iso*opianic acid." By S. N. CHAKRAVARTI and W. H. PERKIN.

"Synthesis of 3 : 10-dimethoxytetrahydroprotoberberine." By S. N. CHAKRAVARTI and W. H. PERKIN.

"Nitrosylsulphuric acid. Part II." By C. W. H. JONES, W. J. PRICE, and H. W. WEBB.

"A synthesis of *iso*naphthathioxin." By A. COHEN and S. SMILES.

"The acylation of diazomethane. A criticism." By T. MALKIN.

"Asymmetric synthesis and asymmetric induction." By A. MCKENZIE and A. G. MITCHELL.

"Some derivatives of the aliphatic glycols." By G. M. BENNETT and F. HEATHCOAT.

"The rearrangement of benzyl phenyl ethers." By W. F. SHORT and M. L. STEWART.

"The chlorination of phthalic acid in alkaline solution." By E. E. AYLING.

"The conversion of tetramethyl γ- and δ-gluconolactones to the corresponding mannonolactones, and of the trimethyl γ- and δ-xylonolactones to the corresponding lyxonolactones." By W. N. HAWORTH and C. W. LONG.

"Mercury compounds of thiophen and selenophen." By H. V. A. BRISCOE, J. B. PEEL, and G. W. YOUNG.

"Basic chlorides and addition compounds from metallic chlorides and hexamethylenetetramine. Exceptional behaviour of nickel chloride." By J. C. DUFF and E. J. BILLS.

"The preparation of some metallic chromates." By S. H. C. BRIGGS.

"Chromatocobaltiammines. Part II. The dichromatotetrammine cobaltiates and the maximum co-ordination number of cobalt." By S. H. C. BRIGGS.

"The potassium and sodium acid salts of normal fatty acids." By T. MALKIN.

"The boric acids." By L. F. GILBERT and M. LEVI.

"The influence of substituents on the Reimar–Tiemann reaction." By H. H. HODGSON and T. A. JENKINSON.

"The methyl urethanes of the isomeric-α-hydroxyphenylethyldimethylamines and their miotic activity." By E. STEDMAN and E. STEDMAN (Mrs.).

"The velocity of decomposition of heterocyclic diazonium salts. Part II. Diazonium salts of the triazole series." By J. REILLY and D. MADDEN.

"The preparation of α- and β-methyl glucoside." By T. S. PATTERSON and J. ROBERTSON.

"The chemistry of the three-carbon system. Part XX. *cyclo*-Pentylideneacetone and *cyclo*pentylidenemethylethyl ketone." By A. H. DICKINS, W. E. HUGH, and G. A. R. KON.

"The vapour density and pressure of ammonium iodide." By R. H. PURCELL and W. DE LANGE.

"Non-existence of isomerism among the dialkyl telluronium dihalides." By H. D. K. DREW.

"Acid and salt effects in catalysed reactions. Part XIX. The catalytic activity of chloroacetic acid in the hydrolysis of ethyl acetate." By H. M. DAWSON and W. LOWSON.
